Of all these 2,570 graduates, practicing in Minnesota or elsewhere, more than half practice "general medicine"—they are "family physicians," that is. No medical school in the Upper Midwest can match this record.

And among all the medical schools of the nation, only Harvard and Johns Hopkins have produced more graduates entering the fields of teaching and research. This, too, Dean Diehl and the citizens of Minnesota can be proud of.

Let us remember the more than 3,000 graduates of the School of Nursing who have gone out from the University during his deanship; the 1,030 medical technologists; the hospital administrators, x-ray technologists, the physical and occupational therapists; the more than 23,000 physicians who have attended the programs of post-graduate medical education on the campus and throughout the state which were developed and expanded under his leadership; the graduates of the School of Public Health whose knowledge and training have spread the name and fame of Minnesota not only nationally but in far-flung countries throughout the world.

I hope that as he looks back upon his life and work at this University, Dr. Diehl will see all these former students, for whom he helped so notably to create opportunity, as a great army on the march into the years beyond his time—advancing to new frontiers in the discovery of new knowledge, ministering to untold numbers who need help and rescue from the dangers of death and disease.

There's a peculiar paradox about this building that will bear his name that is a bit amusing. Dean Diehl, as his close friends and associates know, has a very slight sense of smell. He can sniff trouble, or money for Medicine, a mile away—but he is impervious to other odors.

I remember, as a high school boy years ago, attending a vaudeville show in which two comedians were trying to out-boast each other. One of them boasted he had an uncle who owned 2,000 cattle on a ranch in Texas. The other said his uncle had a ranch in South America on which 5,000 goats were grazed.

"But there's a funny thing about those goats," he said. "They haven't got any noses."

"Well, then, how do they smell?" his partner inquired.

"They smell awful bad," the other chap said.

You see, Dean Diehl would have made a poor comedian. He just has no olfactory sense of humor.

Now the paradox about the building that I mentioned is an olfactory one. Because it will house hundreds of animals indispensable for research, it will have a huge smoke-stack to carry off their odors. Just "wasted money," I'm sure the good Doctor regards it.

But these experimental laboratories will provide a long and seriously needed facility for medical research—and the other phase of the building will house the bio-medical library for which he has struggled so many years.

This splendid structure, indeed, will exemplify much that I have been saying about Dr. Diehl's aims and attainments. For here teaching and research are to be given new strength. And here is witnessed, in the financing of the structure, the contagion of his capacity to mobilize support.

Responding to his appeal, the Legislature appropriated $832,000; the U. S. Public Health Service provided almost a matching amount. Gifts exceeding three-quarters of a million dollars came from individuals and corporations and foundations, with the help of the Dean's faithful friend, Dr. Donald J. Cowling, and colleagues of the Faculty. Notably among additional resources toward cost of the library was $108,000 from the University's "Copavin" trust fund, representing patent right royalties accumulating to the University over the years from the Dean's own research on a product for treatment of the common cold.

Ladies and gentlemen, it is with profound respect, and with most grateful and affectionate regard, that we recognize the productive impact of a dedicated personality upon this institution. How fitting to write in perpetuity on this campus the name of Harold S. Diehl.

It is my privilege now to unveil the plaque of enduring University remembrance in the years to come—and I shall ask the Dean to stand with me as I perform this official act on behalf of the Regents and faculties of the University.

Diehl Hall—A Symbol

HAROLD S. DIEHL, M.D.
New York, New York

Dr. Diehl, Dean Emeritus, College of Medical Sciences, University of Minnesota, is at present Senior Vice President for Research and Medical Affairs and Vice President of The American Cancer Society, with headquarters in New York City.

WHEN I received the invitation to participate in this evening's program, I wondered what I should say in the few precious minutes available to me. Many things came to mind; but first and foremost, I decided that I want to say *many, many "Thank you's"* both for Julia and for me.

I want to say "thank you" President and Mrs. Morrill, or better still, "Freda" and "Lewis," for your constant encouragement, for your unfailing support and, above all, for your wonderful friendship—a prized possession which we hope to keep always.

I want to say "thank you" to the Regents for giving us this memorable evening, for your friendly support in my years as Dean and for authorizing the naming of the new building in my honor. I want to thank the representatives of the State of Minnesota. I want to thank "Bill" Middlebrook, Malcolm Willey, Dean Blegen and many others in the central University administration and on the general University faculty. And, I want especially to thank my colleagues and friends on the faculty of the College of Medical Sciences. To have been associated with you over all these years

has been one of the greatest privileges that anyone could possibly have had. To Julia and me you have been a wonderful family and as such we will always remember you. I want also to thank our many friends for coming here this evening. And finally, I want to thank those who arranged this occasion for inviting our relatives and a few close friends from outside the University group, and especially for inviting our children. Their being here completes the family circle and makes this a perfect evening.

Before proceeding further, I want to admit to a bit of a shock in seeing my name listed on the program as "Dean Emeritus." In time, I presume, I will get used to this but I still feel much like Dr. Evarts Graham must have felt after his retirement a few years ago as Professor of Surgery at Washington University. Concerning this, Dr. Graham said that a few days after his retirement, when Mrs. Graham went to the grocery store, her grocery-man said: "I was sorry to read in the paper the other day about Dr. Graham. What is this condition 'emeritis' that he has? Is it serious, or is it something he will get over?" Mrs. Graham, being quick-witted, responded: "Oh, it is a condition that comes on as a professor gets older. It is something that he just has to learn to live with." In my case, I am sure that I will learn to live with it, but at the moment, it still seems a bit strange.

When my predecessor, Dean E. P. Lyon, retired, he gave me an address entitled: "Swans Sing Before They Die." He took this title from a verse which reads:

> Swans sing before they die,
> 'Twere no bad thing
> Did certain persons die
> Before they sing.

As for me, I am not yet ready to sing my "Swan Song." True, Julia and I have moved from the banks of the Mississippi to the banks of the Hudson. But we are very much alive and are facing the future with interest and enthusiasm and with the hope that in the years ahead we may be able to make a contribution to the vitally important work of the American Cancer Society. This evening, however, I am sure that you will forgive me if I look backward a bit as well as forward.

The copper box to go into the cornerstone which you have filled this evening tempts one to speculate as to what Medicine, the University, the State of Minnesota, the United States, the world and even the universe will be like 600 years from now, when, as I understand it, this box will have to be opened if the contents are to be examined before they disintegrate.

To try to guess what will happen in the fields of medicine and public health in the next 600, 100 or even 25 years, would require more proficiency as a crystal gazer than I possess.

1958 was Minnesota's Centennial year. A hundred years is but a brief moment in the history of the world or even of mankind but more progress was made in the prevention and cure of disease during the last century than in the millions of years which went before.

Will the next 100 years bring an equal amount of progress? Certainly there is every reason to think so; for the rate of scientific advance has never been greater than it is today. So, when our copper box is opened, will cancer, arteriosclerosis, high blood pressure, mental illnesses and possibly even the common cold be only names and of interest historically as the Black Death and the other great epidemics of 600 years ago are of interest to us today? It would certainly be interesting to know.

As for me, however, I am content to live in the present and am thrilled to have the building housing the medical-biological library and the associated medical research laboratories named in my honor.

In a way I feel relieved that you have done this, because otherwise I would be retiring after 38 years on this faculty with my name having been attached to only two things associated with the University. One was the enormous excavation for the Mayo Memorial which, during the year or more that construction ceased because of rising costs, came to be known as "The Dean's Hole" or "The Dean's Folly." Later, when a water-main broke and this hole was partially filled with water, it was called "Diehl Lake."

The other thing with which my name is associated is a recipe which appears under the caption "Harold Diehl's Punch" in the recently published *Curriculum for Cooks,* prepared by the University Hospitals Auxiliary and the Faculty Women's Club of the University. Now this is a good punch, and I am glad to have my name associated with it. I am pleased, however, that these are *not* the only continuing associations of my name with the University of Minnesota.

Seriously, though, you could not possibly have

paid me a greater or more deeply appreciated honor than to associate my name with this building of which I dreamed so long, for which I worked so hard, and which, in the years ahead, will be a symbol as well as the heart of scholarship and of scientific progress in this great medical center. For recommending that this building be named for me, I thank the Administrative Committee of the College of Medical Sciences and the Administration of the University, and for authorizing it, I humbly thank the Board of Regents.

I also thank the Legislature for appropriating the money for the construction of the Library, and I thank the individuals, the groups and the United States Government which provided the funds for the research laboratories. I am particularly pleased also that construction of this building was assured before I retired. As I said last June, I could not possibly have had a finer retirement present than the news that the bids for this building were within the funds available.

I want to thank President Morrill and the Regents also for inviting the members of the Minnesota Legislature to be with us here this evening. For more than 20 years, I have appeared before appropriation committees of the House and the Senate to ask for funds to support the medical school, for medical research and for the University Hospitals. On these occasions, you were always courteous, interested, and generous. As a result, we have been able to develop at the University of Minnesota a great center of medical teaching, medical research and medical service—a center which not only is making distinguished contributions to medical progress but also is bringing distinction to the University and the State of Minnesota. I am sure that you agree with me that the funds which you have provided over the years for this enterprise have been a good investment.

And now may we take a brief look ahead. First of all, let me assure you that I have no doubts or misgivings about the future of our College of Medical Sciences. You have in the Medical School, the University Hospitals, the School of Nursing and the School of Public Health strong and dedicated staffs with the ability, enthusiasm and imagination to continue to move forward. Facilities are adequate, except for the completion of the remodeling of Jackson Hall and Millard Hall. In Jackson Hall, we need to provide teaching laboratories in anatomy and pathology for the larger medical classes which have been authorized. Millard Hall has some areas which are unchanged from the time of their construction more than 40 years ago. These need to be modernized. I hope that the Legislature will provide the funds this year for these important unmet needs.

I do not want to emphasize needs this evening but I would not be honest with you if I did not say that I am disappointed that we did not succeed before my retirement in obtaining funds for the construction of the proposed residence hall for married interns and medical fellows. These are carefully selected young men and young women upon whom future leadership in medicine and medical research depends. They come here to continue advanced studies and to engage in research. Their fellowship stipends are small, yet practically all of them are married and have children. This combination of circumstances plus the shortage of housing near the campus compels most of them to live many miles away from the University hospital and from the research laboratories in which they work; and even so, they frequently have to live under conditions that are disturbing and unfair both to them and to their families. The result is that they are tremendously handicapped in their scientific development and their research activities. Some give up in frustration. To correct this, we have proposed the construction of a moderately-priced housing development for this group within walking distance of the Medical School. I hope that this can be made a reality in the near future. It would, I am sure, pay big dividends in research accomplishments and in the development of our medical leaders for the future.

And now to get back on the track of my remarks about the future. I have spoken of our strong staff and our splendid facilities. In addition to these assets, I would mention especially two more. One is the invaluable interest, faith and support of the Medical School by the people of Minnesota. The other is the able and imaginative young man whom you have chosen as my successor. Dr. Howard was recommended for this appointment by President Morrill, with the unanimous endorsement of the advisory faculty committee. I am certain that no one will ever have reason to question the wisdom of this choice. The future holds great possibilities but it is certain also to present many problems. Dr. Howard, I am sure, will see and take advantage of the opportunities and will deal effectively and constructively with the problems.

Speaking of problems, one which you have already faced and taken steps to meet is the need for training more physicians. Your decision to increase to 150 the number of students admitted annually to the Medical School is clearly justified and forwardlooking.

Whether facilities for the training of still more physicians should be provided by or within the State of Minnesota is a question that is doubtless in your minds. In fact, I understand that it is being raised in the form of a proposal for a new medical school in St. Paul. Over-all in the United States, there is a need for the education of more physicians to keep pace with our increasing population. It does not necessarily follow, however, that this holds true for Minnesota. I would urge therefore that the need for educating more physicians within the state of Minnesota and the possible resources for such training be carefully appraised on a statewide basis by some appropriate body or group. If such a study indicates a real need for the training of more physicians, the question should then be raised whether such training can be best provided by further expansion of the University's Medical School, by the extension of the excellent graduate medical programs of the Mayo Foundation to include undergraduate medical education, or by the establishment of a new medical school. The development and support of a new medical school are tremendous responsibilities and should be undertaken only after most careful and serious study.

As a conclusion to remarks on an occasion such as this, I presume that one should give some advice or exhortation for the future. The only advice that I have to give, however, is keep your sights high; have confidence in yourselves, your University and your State; do not compromise with quality in education, in research or in service to your patients; continue to cultivate the interest and support of the people of Minnesota, physicians and laymen alike, in the work that you are doing, and continue to function as a team within your own college and within the University. Warren Weaver of the Rockefeller Foundation wrote in a recent issue of *Science* (July 18, 1958, p. 128) that "an institution is too big when the whole is no longer more than the mere sum of its parts." Here at the University, I have always felt that among our greatest assets and our most unique characteristics have been the easy exchange of ideas and the co-operation and team work that has existed between individuals, between departments and between colleges. Guard this with care so that it is not lost in the complexities of a large organization.

And finally, Julia and I want you to know that our many years with you have been happy and rewarding ones, that we will never forget you and that we hope you will not forget us.

HEARING AID INDUSTRY CONFERENCE TRANSCRIPT AVAILABLE

A transcript of the first joint conference among the professions and commercial elements serving the hard-of-hearing is now available, the Hearing Aid Industry Conference, sponsor of the conference, has announced.

The conference was held in New York City on February 17, 1959. Its purpose was to exchange information on the most recent advances in service to the hard-of-hearing in surgery, medicine, rehabilitation and technology. The sponsor suggests that the transcript may be of interest to all persons in these fields, especially since participants indicated the session had helped bring greater understanding among the various fields represented.

Represented were the American Academy of Ophthalmology and Otolaryngology, the American Hearing Society, the New York League for the Hard of Hearing, the Bureau of Medical Rehabilitation of the New York State Department of Health, the Society of Hearing Aid Audiologists and the HAIC.

Requests for transcripts should be made to Hearing Aid Industry Conference, 2900 W. 36th Street, Chicago, Illinois. Since the supply is limited, requests will be honored on the basis of date of receipt, one transcript per request.

60-30-10

These several circumstances have combined to stimulate the application of the 60-30-10 Law to current educational decisions:

1. The tale of a child's sullen behavior provoking from the mother the comment, "Isn't it terrible, the sort of kids they're raising in schools nowadays?"
2. Recurrent discussions about the need for more, bigger, and flossier school buildings.
3. The statement of the 60-30-10 Law by Dr. Milton Friedman *et al.**

That the principle of the 60-30-10 Law is applicable to our schools and education is self-evident. For the moment, and for the sake of illustration, accept the value judgments; i.e., 60 per cent of the effectiveness of schooling depends on the students put into the educational system; 30 per cent depends on the quality of the teaching; and 10 per cent depends on the physical plant in which the teaching is done. Then it follows that school boards who are bending all their efforts toward raising funds for more, bigger, more plush school buildings should start directing this energy toward employing better and better, and more inspiring, teachers (and weeding out some of the duds currently secure under the protective umbrella of tenure-is-supreme, professional-ability-be-hanged). Further, that parents who are harrying school boards to remedy the ten thousand ways in which our schools are failing, should themselves do something about injecting higher quality raw material into our educational system.

Marriage is the only socially sanctioned framework within which human reproduction can occur, and the choice of marriage partners (and therefore human breeding) remains a fairly random proposition. So eugenic techniques for improving the raw material fed into the schools are stymied. This leaves, however, abundant scope for even randomly self-chosen parents; to wit:—the inculcation in children of a desire for making the most of their abilities (what better goal for education?); the inspiration of children to eschew the life of ignoble ease and to occupy their energies with broadening and useful pursuits; the implantation in children of the awareness that a busy life is not only more likely to be productive but also to be happier, that even if work may not be praiseworthy *per se*, it is a laudable means to virtuous ends; the instillation in children of a wholesome sense of responsibility.

All these sound formidable? Don't sell the children short. Try these principles on them. Their cooperative acceptance and discharge of such responsibilities runs a higher titer per year of age than any of us can again reach.

H.G.M.

ADDENDUM: Two seriously critical students from a *new* high school reviewed the proof copy of this editorial and advocated changing the 60-30-10 values to 50-40-10, or even 45-45-10. Note the agreement with the "10" figure.

*"*The 60-30-10 Law.* The principle of this law is not new, but we have assigned to it value judgments. The 60-30-10 law is as follows: The values of the factors which influence irradiation cures are 60 per cent for the nature and extent of the tumor, 30 per cent for the skill and experience of the therapist, and 10 per cent for the modality employed . . . ." Am. J. Roentgenol., 81:415, March, 1959.

ESSENTIALS OF MONONUCLEOSIS

The following observations on mononucleosis have been gleaned from observing the impact of this disease on the student body at a state university. One of the most incomprehensible features of mononucleosis is the fact that a student ill with pharyngitis and fever apparently cannot transmit the disease even on intimate oral contact. Thus, "a history of exposure" so helpful in other instances is singularly lacking in mononucleosis. Transmission appears to be by way of an asymptomatic carrier, with no clinical or laboratory evidence of the disease. In this population the incidence among married students is so disproportionately low as to lend strong circumstantial support to the view that transmission is usually the result of a type of kissing favored by newly intimate or engaged couples.

Patients with this disease commonly complain of sore throat, malaise, and fatigue. Cases without

pharyngitis are classified as atypical, (typhoidal). Some students complain of a rather severe generalized headache lasting several hours daily during the prodromal period. Complaints of cough and myalgia are so uncommon as to point to some of the commoner influenza-like diseases. Few cases will be overlooked when honest attention is focused on the following signs:

Fever—Present in all, usual duration about nine days.

Adenopathy—This is the sign on which presumptive diagnosis hinges and can be found in almost all cases. When the examiner stands on the right side of the seated patient, careful palpation, with the tips of the fingers of the left hand from the back of the neck, will demonstrate enlarged left posterior cervical nodes in 99 per cent of cases by the end of the first week of illness. Right posterior cervical adenopathy, while an erratic runner-up, is of second importance. Axillary, epitrochlear and inguinal adenopathy can sometimes be elicited but their importance has been overstressed. Significant anterior cervical adenopathy suggests concurrent Vincent's infection or streptococcic pharyngitis.

Pharyngitis—Present in 90 per cent, may develop late. Palatine petechiae or a white tonsillar exudate appear in about one fourth of cases.

Splenomegaly—Present in 70 per cent male and in 30 per cent female patients.

Hepatomegaly—Present in 30 per cent, jaundice in 5 per cent.

Rash—So rare in patients untreated with antibacterial agents as to suggest some other diagnosis.

Most patients have a definite leukocytosis. Blood smears as prepared in the average laboratory for routine differential counts are too heavy to permit accurate identification of atypical lymphocytes; smears should be about one-half the usual thickness. Atypical lymphocytes in percentages ranging from 20 to 67 are present during the midfebrile period of the illness and are sustained at this level for a week or two. Smears made after the temperatures have returned to normal often do not demonstrate these cells clearly. Neutrophil counts are usually lowest a few days after normal temperatures appear and range from 6 to 49 per cent. All patients with a diagnostic smear, pharyngitis and cervical adenopathy will develop a heterophil titer of at least 1:56. This statement is based on over 700 cases, in which it was possible to check this test through the seventeenth day of illness. Thus, the patient with mononucleosis will have not one or the other, but both hematologic and serologic evidence of the disease. Absorption tests are unessential in patients with classic clinical and hematologic signs of mononucleosis. In my opinion, the practice of reporting diseases with gross hematologic or serologic deficiencies as mononucleosis is contrary to available evidence, serves no useful purpose and is responsible for most of the confusion about this disease.

It should be remembered that (1) positive heterophil tests on unabsorbed serum are present in other conditions, (2) tests may remain positive as long as one year after the illness, or (3) once negative may be reestablished during some subsequent illness. Consideration of these points illustrates the fallacy of basing the diagnosis on the positive heterophil test alone. Atypical lymphocytes will be absent in these situations, while the patient with acute mononucleosis will have both a positive heterophil test and a high atypical lymphocyte count.

At the university health center, mononucleosis is not a protean disease studded with the galaxies of bizarre clinical syndromes commonly described in the literature, but a disease with a remarkably clear, stereotyped picture. It is significant that accounts of mononucleosis with the most atypical features frequently lack common clinical or laboratory findings, sometimes both. For the present, it would seem appropriate to reserve the term mononucleosis for cases having both hematologic and serologic findings to support this diagnosis.

THE TRANQUILIZERS

The ability to classify, to *name* things, is man's basic means of communication. However—as indispensable and as comforting as they are—names have no magic in themselves. Naming does not necessarily imply complete understanding; for example, when we describe an illness as "functional," we are not only communicating knowledge, but also revealing ignorance.

So it is with mental illness. The names that psychiatrists have given to the many forms of mental illness have undoubtedly been helpful to understanding. It would be a mistake, though, to expect them to have precise limitations which, because of the nature of mental illness, they cannot have. Diagnostic labels are of little help when we try to pinpoint specific indications for tranquilizing drugs.

Tranquilizers act to allay the tension and anxiety that may accompany many different mental conditions. Patients who demonstrate hyperactivity (which may range from extreme restlessness to destructive violence) are those for whom the drugs are most often given and who usually respond the most dramatically to them. However, investigators have also reported success in using tranquilizers to treat depressed and apathetic patients. At first glance, this result seems paradoxical. After all, one might think that depressed patients would require a psychic change opposite to that produced by a tranquilizer. In general, this may be true and, when given to depressed patients, some tranquilizers have only deepened the depression. However, when anxiety is the underlying cause of depression, it does not seem paradoxical for a tranquilizer which effectively lessens anxiety to lessen the depression caused by anxiety. Hopefully, as our knowledge of what causes mental and emotional stress increases we will be better able to pinpoint the action of tranquilizers and to design drugs which will specifically treat certain psychoses and neuroses. As of now, we can say that almost all hyperactive patients (including agitated depressed patients) are likely to respond well to an effective tranquilizer, and that by relieving the anxiety accompanying depression, some tranquilizers may be of help in treating many depressed, apathetic and withdrawn patients.

Our knowledge of mental illness is limited. Our knowledge of the usefulness of tranquilizers is chiefly empirical. Trying to describe exactly how the tranquilizers act is a little like it would be trying to describe how penicillin acts if Fleming's discovery had occurred before Pasteur's.

Animal Experiments

Male Siamese fighting fish are, to say the least, unsocial. When two are placed together in a bowl of water they will usually fight until one or the other is dead. However, when a tranquilizer is added to the water, mortal enemies often find peaceful coexistence possible. Observing a drug's ability, if any, to modify the fighting instinct of these fish provides researchers with a rough preliminary test for screening drugs which may have tranquilizing activity.

An important part of the animal research done by pharmaceutical houses is designed to screen compounds in an attempt to find useful new psychotherapeutic agents. One ingenious and valuable screening test used in the Smith, Kline & French Laboratories is based on Pavlov's technique for bringing about a conditioned response. Rats are trained to leap on a pole when given a slight electric shock at the same time a buzzer is sounded. Eventually, they leap at the sound of the buzzer alone; for they learn to associate buzzer with shock, both with trouble. After receiving a barbiturate or other sedative, the conditioned rats no longer respond to either the buzzer or the slight shock. After receiving an effective tranquilizer, the rats no longer respond to the buzzer, but *do* respond to the shock. This ability to block the *conditioned* response without affecting the normal reflex, distinguishes most compounds which exert a true tranquilizing action.

Screening tests are only the beginning of a long series of animal experiments which may take years, and then not lead to anything. However, if research on animals proves that a compound is safe and probably effective, clinical research begins. Most clinical research on a new tranquilizer tries to determine the drug's general efficacy in treating various types of mental illness. As the drug becomes more accepted, clinical research usually becomes more sophisticated. For example, one continuing controlled study of chlorpromazine is being conducted on released mental patients whose progress has been, and will be, followed for many years. Hopefully, the study will reveal the need for, and efficacy of, long term therapy.

There are many other interesting areas of current research: Research to "test tests"—that is, to evaluate standard psychological tests and to develop new ones—may provide objective, precise methods for judging the effect of tranquilizing drugs; animal research to determine behavioral responses to certain stimuli may shed some light on the possible causes of neuroses and psychoses. There are others. But, of course, it's impossible for this editorial to take more than a brief look at a small portion of what is really a vast amount of research. Research whose ultimate goal is victory over mental illness.

MAURICE R. NANCE, M.D.

President's Letter

HOSPITAL ACCREDITATION

Since the Joint Commission on Accreditation of Hospitals was set in motion some seven years ago, you have heard many pros and cons. You have read many articles written by doctors and administrators vehemently protesting the so-called "policy system" of the Commission. Others have been complimentary in their comments.

It has been stated that "inertia and a reluctance to improve are responsible for the fact that almost 50 per cent of the hospitals in the United States are still not accredited." Nevertheless, hospital accreditation is here to stay and there is a growing interest, stimulated by many lay magazines, in accreditation on the part of the public.

There seems to be an inherent resistance on the part of many hospitals and doctors to achieve the status of accreditation. This status is actually not as exalted as might appear, inasmuch as accreditation only required hospitals to meet a minimum standard of quality. It is a voluntary program and actually in existence for forty years beginning with the late Dr. Malcolm T. MacEachern. At present, its purpose is to create in all hospitals an environment that will insure the best possible care of the patient.

In the foreword on Standards by Kenneth B. Babcock, M.D., Director, he states,

"These standards are considered necessary to insure the quality of medical care in hospitals which the Joint Commission can faithfully recommend to the public. They are not arbitrary or rigid in spirit, yet they require general conformity to achieve accreditation by the Commission. To qualify for accreditation, the hospital must have at least twenty-five beds, have been in operation at least twelve months, and, if located in the United States, be listed in the administration's guide issue of *Hospitals,* published by the American Hospital Association. There are basic principles and methods of procedure, dependent upon the type, size, degree of departmentalization and resources of a particular hospital."

In Massachusetts, a law governing hospital licensing (signed by the then Governor Christian A. Herter in 1956) was amended to clarify the state health department's status in examining medical records of unaccredited hospitals. Under the amendment the health department may order an examination of the medical records and "staff qualifications of all proprietary hospitals, sanatoria and all voluntary hospitals not fully accredited by the Joint Commission and may order such an examination of the medical records of other hospitals as said department may deem necessary." The law states also that hospitals must pay for such examinations.

Certainly, we have too many laws now that aggravate us but there may be more to come. I think it behooves us all as physicians to get on the band wagon and keep our house in order. I have served on records and audit committees and sometimes it has been a thankless job. Nevertheless, surveys are beginning to show that these committees and the tissue committees are producing amazing results in raising hospital standards. There is an old adage that "if you can't beat them you had better join them." However, if we work hard and diligently enough, we can join something we like rather than have to join something by compulsion that we will never enjoy.

HOSPITAL ADMISSIONS STUDY ANNOUNCED

A $200,000 study has been authorized by the Executive Committee of the Health Information Foundation to determine why more than 20,000,000 Americans or one out of eight enter a hospital each year. The study will be conducted jointly by the National Opinion Research Center of the University of Chicago and the Health Information Foundation.

A sample of admissions to hospitals in Massachusetts will be examined through the approval and cooperaiton of the Massachusetts Medical Society, the Massachusetts Hospital Association and the Blue Cross-Blue Shield Plans in that state. The 2½-year study will attempt to ascertain the non-medical factors and family situations which lead to hospital utilization as well as medical reasons given by physicians.

According to George Bugbee, Foundation President, admissions to hospitals are governed not only by medical diagnosis but by concepts of patient comfort, optimum conditions for treatment and by many personal and social factors.

"These same factors may also affect the patient's length of stay in the hospital," he said, "and it is important to study them if we are to establish a reasonable definition of the role of the hospital."

Such a definition is essential, he explained, because it governs interpretations of use or possible "overuse" of health insurance benefits.

"There have been allegations in recent years that there is 'abuse' or 'overuse' of hospitalization insurance," he said, "and that such 'overuse' adds substantially to the cost of care. We hope that the new study will bring greater insight to concepts of what constitutes adequate use of our hospitals."

Mr. Bugbee said the survey is one of a group of major studies of voluntary health insurance sponsored by the Foundation. The foundation was organized in 1950 as a contribution by the drug, pharmaceutical, chemical, and allied industries to research and education in the social and economic aspects of medical care.

According to the Foundation, many non-medical considerations are increasingly important influences on admissions to hospitals, and consequently, on the cost of care.

"The degree to which individual judgment is involved is one of the objectives of our study," said George Bugbee. Among others he included the individual's attitude toward hospitalization, his home and job situations, his ability to meet costs, and his doctor's habits, beliefs and experiences.

"We need to know much more about what the public expects of hospital service," Mr. Bugbee said. "Our study, however, will not attempt to evaluate current use of such service, but rather will describe it and thus be of value to those concerned with defining what may be considered justifiable and legitimate use of hospital care."

"Before limitations are imposed on money being spent for hospital care or the number of people being admitted to hospitals it is important that we have full information on why hospitals are now being used so much more widely," he said. "That is the purpose of our study."

"Overuse of services would be wasteful," Mr. Bugbee said. "On the other hand, undue limitations could stand in the way of needed medical care or could delay progress."

HOSPITAL HEAD TELLS HOW MEDICAL ADVANCES AFFECT HOSPITALS

The superintendent of the University of Chicago Clinics, Mr. Ray E. Brown, recently pointed out that medical advances not only influence the community's total hospital bill, but also affect the community's utilization of hospitals.

"In the first place," according to Mr. Brown, "these medical advances now permit doctors to offer treatment to patients whose condition was classified as hopeless and incurable a few years ago. These patients represented no expense to the prepayment plans because there was no treatment for them.

"If one reviews the average hospital's census today it is likely that a goodly per cent of the patients will be undergoing therapy that was unknown just a few years ago. Much of this new therapy is difficult and of long duration.

"The effort on behalf of these patients consumes an increased number of more costly hospital days that represent a net addition to the pay-out total of the community's prepayment plan," he said.

Mr. Brown pointed out that it is difficult to answer the question of whether some patients with prepayment overuse the hospital.

"The essential question in this connection is not concerned with whether those with prepayment coverage used more hospital care. If prepayment is serving any social purpose at all it would be expected that its members would have had better financial access to hospital care."

Medical items not covered by prepayment, such as prescription sales, have increased tremendously during the past ten years, and thus offer some evidence that the public is interested in health care "for its own sake and not as a means of beating the prepayment game," according to Mr. Brown.

In an article published in *Hospitals,* Journal of the American Hospital Association, Mr. Brown noted that there are the cultural and economic, as well as medical forces, which affect how many people are admitted to hospitals but are beyond the hospitals' control. Changing characteristics of the American population described by Mr. Brown in *Hospitals* include the following:

—experts say that by 1975 there will be an additional eight million people over sixty-five—a group with higher-than-average medical care needs whose hospital costs are estimated to be from three to four times greater than for those under age sixty-five;

—the dependent child population, those under eighteen, is expected to increase some twenty million or about 35 per cent by 1975. This means that the number of dependents covered under prepayment family certificates (for hospitalization and other services) will increase faster than the total number of certificates;

—concepts of illness are changing; an increase in the number of working wives, for example, means less care for the sick at home and more use of hospitals even for the less serious illnesses;

—the public is becoming increasingly aware of the value of hospital care and such care is "becoming an accepted component in the average American's standard of living."

FOR SALE—ONE UNION CLINIC

The *New York Times* recently reported that a union health center in which two locals of the Amalgamated Meat Cutters and Butcher Workmen's Union invested $240,000 has been offered for sale or sub-lease. Arnold Cohen, Administrator of the Labor Health Institute said that the center had been used for four years by Locals 342 and 640. According to Mr. Cohen, members of the locals would receive better care under group health plans.

HEALTH INSURANCE COVERAGE IN MINNESOTA REACHES NEW HIGH

Benefit payments by insurance companies to the people of Minnesota who are covered by health insurance policies reached a new high during 1958, reports the Health Insurance Institute.

In the period from January 1 through December 31, 1958, an estimated $53.7 million was paid out to help cover the cost of hospital and doctor bills, and to replace income lost through sickness or disability. This represents a 6.2 per cent gain over the 1957 figure of $50.5 million, and is based upon reports from insurance companies doing business in the state.

The rise in benefit payments in Minnesota was reflected in the figures for the nation as a whole, the Institute noted. Persons protected against the expenses of hospital and medical care and treatment received a total of more than $2.6 billion in benefits from their insurance company policies in 1958, up 8.3 per cent over the previous year's high of $2.4 billion.

By the end of the year, an estimated 70 million persons were covered by health cost policies bought from insurance companies, more than all other types of voluntary health plans combined.

GREATER DOCTOR-HOSPITAL-INSURER COOPERATION URGED

Dr. Anthony J. J. Rourke, internationally known hospital planner and consultant, addressing 300 insurance company executives at the Annual Meeting of the Health Insurance Association of America in Philadelphia, May 5, urged better liaison and increased cooperation between doctors, hospitals and health insurers to curb spiraling medical care costs.

Said Dr. Rourke:

"As soon as your industry and our profession can sit down and properly evaluate and measure the portion of increased costs which are due to the substitution of adequate care in place of inadequate care and that portion which may be considered abuse, we will have taken a long step toward a better understanding."

He said that medicine, through its "open skies" plan and accreditation program, had taken "the first long step" toward creating the climate for better understanding. "I know of no other group that bares its inner secrets to the eyes of other professionals in competitive positions in a way similar to that exercised in the accredited hospitals in the United States and Canada," he asserted.

Dr. Rourke, who has worked with hospitals in Alaska and Central America as well as in this country, said medicine had established "four committees of major consequence" which considered such problems as unnecessary hospital admission, increased length of hospital stay, unnecessary procedures and "the absence of stop-orders on expensive and dangerous drugs."

"Organized medicine knows that as prepayment is available, as hospital beds are sufficient and as

an adequate number of physicians have been trained, some increased utilization will occur," he said.

"It behooves the profession of medicine to make sure that this increased utilization represents only needed medical and hospital care and does not reach the point which can be considered over-utilization.

"The field is now fomented with arguments charging abuse, exploitation, unwise methodology and coverage, laxness in administration, and a host of other evils," he added.

He strongly urged larger medical societies to employ health insurance experts on their staffs and health insurance companies to appoint to their staffs more physicians with special knowledge of the fields of prepayment and industrial medicine.

"Liaison between doctors, hospitals and prepayment programs is badly needed," he said.

Dr. Rourke, who spoke on the subject, "Hospital Accreditation—The Significance to Health Insurance," also called for a "summit" session of the health insurance service benefit groups and the indemnity benefit groups.

He said a "cold war" existed between these groups, adding:

"The public, through its elected officials, has been screeching for investigations of the health professions. I can assure you that when it is aware of all the implications it will be screeching for a significant 'summit' session in which to unshackle prepayment into a free world.

"As long as competition prevents the payment of increased premiums adequate to furnish the care the public wants, we will continue to mistake the effect for the cause.

"Competitive surgeons meet and argue and the patient benefits. Competitive carriers (service and indemnity) must meet and argue as truly 'pro bono publico' groups.

"As long as we have no accreditation standards for the purveyors of coverage the public will suffer. Now is the time for your groups to take a page from the physicians' accreditation notebook and act."

MEDICAL AND VOLUNTARY HEALTH INSURANCE PLANS FOR SENIOR CITIZENS ACCELERATED

Dr. Leonard W. Larson, Chairman of the American Medical Association's Board of Trustees said recently that medicine and voluntary health insurance are protecting the nation's senior citizens at a "rapid, accelerated pace." However, he warned that "we have only about one year left . . . a year in which we must work fast and vigorously" to provide coverage for additional millions of the aged or be confronted with tax-paid health care.

He noted that the nation must be concerned "not about the specific provisions of the Forand Bill—which can be amended all over the lot—but about the basic principle involved."

The bill, introduced in Congress by Rep. Aime Forand (D., R. I.), would provide hospital benefits and certain other services to persons receiving Social Security retirement and survivorship payments.

Addressing the Health Insurance Association of America at its annual meeting in the Bellevue-Stratford Hotel, Philadelphia, Dr. Larson said the principle of adding service benefits to the Social Security program, which so far has been limited to cash payments on the "floor-of-protection" concept, "would completely alter the nature of the program."

"It would open the door for evolution of a system of tax-paid health care for the entire population," he declared. "Every two years—in the even years of Federal elections—the familiar process of amendment and expansion would roll faster and farther. Such legislation first would undermine and eventually would destroy our system of voluntary health insurance and the private practice of medicine."

Dr. Larson took note of the rapid growth in health insurance coverage for senior citizens over the past few years and the "hopeful developments" of the last twelve months which have accelerated the pace even more. He cited the joint meeting of last October of representatives of the AMA, health insurance companies, Blue Cross and Blue Shield which resulted in various actions by each of these groups to extend health care cost protection to the over age-65 population.

But because health insurance coverage for older people is "the most urgent, critical field of activity" for Congress in the 1960 election year, Dr. Larson said, medicine and insurance must "work together more closely than ever before" to provide protection for aged. He added:

"I honestly believe that if medicine and insurance will co-operate in a dramatic, convincing drive to increase the coverage of people over 65, we can take the steam out of those who advocate any Forand-type program. This will require open, clean, keen competition between voluntary insurers of all kinds—Blue Cross, Blue Shield, private insurance companies and other sound agencies in the prepayment field—plus the wholehearted support of the medical profession."

Dr. Larson declared that the future of private medicine in the United States "no longer depends primarily upon scientific progress and the professional competence of physicians," adding:

"In these times of swirling social, economic and political pressures, private medicine may stand or fall in relation to the success or failure of voluntary health insurance. . . ."

RECENT MEDICAL LEGISLATION TRENDS REVIEWED

A number of legislative measures, vital to medicine, have recently been introduced or will be introduced in the near future by the 86th Congress.

An analysis of several of these measures is given below for your information:

U. S. Doctor Shortage Study Urged

A bill to provide for the establishment of a commission to study the shortage of doctors of medicine in the United States, was introduced in the House Interstate and Foreign Commerce Committee, April 15, 1959.

This bill would authorize a one year study of the shortage of doctors in the United States. The study is to be undertaken by a twelve member group to be known as the "Commission on the Doctor Shortage in the United States." Its members would consist of two Senators, two members of the House of Representatives, two representatives from the Executive Branch of the Government and six members from private life. The medical profession would have representatives in the last group. The Commission would give particular attention to: The policy of medical schools in limiting the number of student admissions; the number of physicians graduated annually from medical schools in the United States; the extent to which hospitals must seek foreign doctors to fill internships; the number of U. S. citizens studying medicine in foreign countries who could not gain admittance to medical schools in the United States; and the extent to which graduates of foreign medical schools are permitted to practice medicine in the United States.

The Commission is to submit a final report to Congress not later than one year after the enactment of the Act. The report may contain recommendations and proposals for Constitutional amendments, legislation and administrative actions which in its judgment are necessary to carry out its recommendations.

Tax Deductions for Medical Expense Urged

According to a bill (H.R. 6415) introduced April 15 in the House Ways and Means Committee, tax payers, aged 65 and over, would be entitled to increased medical deductions.

Present tax laws provide that a tax payer in this age group may deduct only the amount of medical expenses for medicine and drugs which exceed one per cent of his adjusted gross income. The proposed law would authorize a deduction from gross income equal to the cost of all medicine and drugs if the expenses incurred is primarily for the care of the taxpayer and his spouse.

Chiropractic Bill Introduced

Chiropractic interests are again striving for a passage of legislation which would permit veterans to utilize their services on an out-patient basis on government expense. Although neither House has taken such legislation seriously in the past, proponents of the cause feel that this may be the right time to gain recognition. Sponsors of companion bills are Representative Edith Nourse Rogers of Massachusetts, and Senator William Langer from North Dakota.

Physical Disability—Social Security Benefits Transfer Urged

Representative Charles S. Bugser of California has introduced H.R. 5623 which provides that physical disability determinations for social security benefits shall be transferred from authority of state agencies to that of Department of Health, Education and Welfare.

U. S.-GROUP HEALTH CONDUCT PREPAID MENTAL CARE EXPERIMENT

The Federal Government and Group Health Insurance, Inc., of New York City, have launched an experiment which entitles a cross section of 30,000 Group Health members in Greater New York, psychiatric services in office and hospital at a fraction of the actual cost. The experiment is to be conducted over a two-year trial period with a $300,000 grant from the National Institute of Mental Health to finance the project.

Observers noted that this will mean subsidization of private, voluntary health insurance in order that broader benefits may be received without increased charges. Major part of the expense will be borne by the $600,000 special pool contributed in equal parts by Group Health Insurance and National Institute of Mental Health.

It may be noted that few nonprofit or commercial health insurances in force today provide coverage for mental and nervous ailments or their prevention.

The results of this survey could play an important role in determining the feasibility of broadening benefits and determining future premium costs.

WHY PEOPLE RESIST VACCINATION EFFORTS, SURVEYS SHOW

Recently, the California Department of Public Health conducted a survey among uninoculated citizens to determine why people resist vaccination efforts. The results indicated that the greatest reasons for not obtaining protection were fear and procrastination.

Of the people interviewed, 14 per cent doubted the safety of the vaccine; 46 per cent of the uninoculated said they were too busy or couldn't be bothered. Expense, according to the survey, was a problem to 15 per cent of those earning under $2,000 a year. Twenty-four per cent of the interviewees with children under six years thought their offspring were too young for the shots.

This year polio inoculation campaigns will be directed toward those hard-to-persuade groups who have resisted previous efforts. If your medical society is planning to round up these stragglers a survey like California's might point up who the laggards are and why they aren't getting their shots. Then publicity can be aimed in the right direction. Contact your local health department, voluntary health agencies or women's auxiliary for help.

For a summary of the progress in poliomyelitis vaccination in Minnesota, see "Polio Protection Step-up Urged by Minnesota Department of Health" in the Public Health section of this issue of MINNESOTA MEDICINE.

RING, TELEPHONE, RING

The telephone is indeed an annoyance as well as a convenience for everyone, notes the president of the Worcester District Medical Society, Worcester, Massachusetts.

For the young physician, the ring of the telephone is the clarion call of a new patient.

For the older physician, it interrupts his office hours and his needed sleep.

For the sick patient, the telephone is a quick way to summon help.

Years ago the sick patients' relative or neighbor came in a buggy or an early model car to the physician's house, routed him out of bed if the hour was late, and brought him to his task.

Now he telephones.

His call is answered by someone.

It may be answered by the impersonal voice of a secretarial service which makes every effort to advise him.

It may be answered by the physician himself.

It is the call that is answered by the physician that is of primary importance to us as a Society.

Most of us realize that when we pick up the telephone to answer a call for help, we represent doctors all over the nation. We do not turn down the call. We are not abrupt. We do not say that we do not make house calls and hang up. We assume responsibility and talk to the caller. We get the name, address, and telephone number. We tell the patient that we will go if we are able and willing.

Very often we are unable to throw on the harness and go to the fire described over the telephone. In such cases a responsible physician sends a doctor in his place.

There is no situation for any of us which calls for a reply that "We do not make house calls," without an offer to send a substitute.

We must be a little better than the better paid plumber and respond to house calls, or send someone in our place.

We respond to calls by picking up the telephone. We assume some measure of

responsibility by that act. Referring the call to the emergency service in this period of our Society's growth does not solve the problem.

We suggest that after picking up the phone that you go and see the patient, or offer to send someone. If the offer is not accepted, responsibility ends. If the offer is accepted, it is better that you find a doctor than for the patient to go through the yellow pages of the telephone without guidance.

In summary: If you pick up the telephone—you are in charge of our public relations.

WHO, WHEN, WHERE, WHY AND WHAT?

Who knows when you, a member of the medical profession, will be called upon to prepare a news release for broadcast or publication.

What you say and how you say it can be best expressed in the form of a news release.

James R. Gay, M.D., Chairman of the Committee on Public Relations of the Northampton County (Pennsylvania) Medical Society, notes the following suggestions for preparation of news releases by individual physicians or county medical societies.

Basically, these suggestions are fundamental in general news writing. However, they have an added perspective because they have been compiled by a member of the medical profession.

"The most effective method of issuing medical news to communications media is to prepare a written news release. It is recommended that each item be drafted and edited several times before being accepted by the authors.

"It is not difficult for a physician to become proficient at writing news stories. One method is to collect sample articles from daily papers and practice styles employed by professional writers.

"*Preparation*—News releases should be double spaced typed on plain white manuscript grade paper stock (8½ x 11). The name of the society is typed in capital letters across the top of each page. Be sure to number pages in upper right corners.

"*Timing of Release*—Most medical news will be offered for immediate use. Type (for immediate release) at beginning of story. If it is desirable to break a story in an evening paper, the release time of 6 a.m. and exact release date should be typed on the first page. Articles for appearance in morning papers should be designated for release at 6 p.m. on specified date.

"*Distribution of Release*—It is recommended that medical news be issued to all area newspapers and radio stations. A copy of the release should be mailed to the Public Relations Committee. In case of doubt about the propriety of the medical news story, it is suggested that the Public Relations Committee be consulted.

"*Avoid Public Controversy*—Medical news should be accurate and factual. Every effort must be made to avoid provoking public controversy. This statement does not imply that the society will refrain from supporting unpopular causes. Controversial subjects should be referred to the president or one of the vice-presidents, for necessary action.

"*Medical News*—Almost everyday, a physician encounters some event of interest to the general public; achievements of members; announcement of meetings; appointment of committees; attendance at national meetings; biography of new members; bulletins during epidemics; election of officers; human interest incidents; medical service developments; participation in community activities; preparation for disasters; preventive medicine suggestions; publications by physicians; scientific advances by members; and scientific programs."

EFFECTIVE PUBLIC RELATIONS URGED TO COMBAT GOVERNMENT MEDICINE

Attainment of the most effective public relations, is essential "if we are to keep medicine in the hands of the medical practitioner and not hand it, by default, to some government agency or bureau," according to Harry J. Loynd, President of Parke, Davis & Company.

In an address delivered before the Michigan Clinical Institute in Detroit, Mr. Loynd warned: "If we are to avoid further Federal legislation, spurred by public misunderstanding, the health team must explore all avenues and join together to support a mutually beneficial program of public information and communication, based on nothing but facts; in short, a good sound public relations program."

He described today's medical care as "the biggest service and commodity bargain that any person will ever buy in their entire lifetime."

Committee Action

COMMITTEE ON HOSPITALS AND MEDICAL EDUCATION

Hospital Construction
College of Medical Sciences
Medical Education
Nursing
Medical Technology

Hospital Construction in Minnesota

The Committee noted with pleasure the report of the Minnesota Department of Health indicating that during 1958 nineteen new hospitals or hospital units in the state were completed while an additional thirty projects were under construction. Nineteen of the programs were accomplished with the assistance of the Hill-Burton program, the remainder without such assistance. Altogether, the new construction already completed during 1958 will provide 1022 general beds, while projects under construction will ultimately provide an additional 1846.

Colleges of Medical Sciences

The year was marked by the retirement on June 30, 1958, of Dr. H. S. Diehl, who had served the University of Minnesota for more than forty years and for twenty-three years had been Dean of the Medical Sciences. In the spring of 1957, officials of the American Cancer Society offered Dr. Diehl the newly-created post of senior vice president for Research and Medical Affairs and deputy executive vice president. Faced with compulsory retirement from the University in June 1960, and bearing in mind that the proposed Cancer Society post would permit him to contribute significantly to American medicine for several years beyond this time, Doctor Diehl reluctantly decided to advance the date of his retirement and to accept the new position, a decision made only after much serious reflection and with due consideration of the many factors concerned. He began his new duties on November 1, 1957, but continued to serve as Dean of the Medical Sciences on the basis of a part-time leave of absence during the remainder of the academic year.

For nearly a quarter of a century, Dr. Diehl has presided over the fortunes of the College of Medical Sciences with consummate skill during a period of remarkable development and expansion, a period of momentous change in medicine, a period in which Minnesota took its place among the nation's finest medical schools. A wise administrator with a thorough knowledge of all aspects of medical education, Dr. Diehl is widely recognized in this country and abroad as one of the nation's outstanding leaders in this field. His retirement leaves a void which will be most difficult to fill, and he will be sorely missed by his friends and colleagues for both personal and professional reasons.

Dr. Robert B. Howard, who had served as Director of the Department of Continuation Medical Education since January 1952, was named Associate Dean of the Medical Sciences, effective October 1, 1957, and he thus served as the principal full-time administrative officer of the College during the period of Dr. Diehl's partial leave of absence. On June 13, 1958, President Morrill, following consultation with an advisory committee that he had appointed earlier, recommended to the Board of Regents the appointment of Doctor Howard as Dean of the Medical Sciences, effective July 1, 1958. This recommendation was approved by the Regents.

Medical Students

In June 1958, 113 students were graduated and in June 1959, 116 students are being awarded the Doctor of Medicine degree by the University of Minnesota. The number of students admitted to the Medical School in September 1958, was 139, while 150 were admitted in September, 1959.

Graduate Medical Training

The State of Minnesota continues to occupy a leading place nationally and internationally in graduate training in medicine, almost all of which is carried out under the Graduate School of the University. During the 1958-1959 academic year, more than 1000 graduate students were enrolled in the basic medical sciences and the clinical specialties of medicine, including those enrolled in the Mayo Foundation program in Rochester and those enrolled in the Medical School program in Minneapolis which utilizes for graduate training in the clinical fields, not only the University of Minnesota Hospitals, but also Minneapolis General Hospital, Minneapolis Veterans Administration Hospital, Ancker Hospital in St. Paul, the Gillette State Hospital, and several private hospitals in the Twin Cities.

Continuation Medical Education

The Department of Continuation Medical Education, which presents each year a series of continuation courses for physicians, continues to provide the practicing physicians of Minnesota with an opportunity to review significant fundamental material and to learn of important advances in medical practice. The unique facilities

In smooth muscle spasm...

• controls *stress*

• relieves *distress*

Pro-Banthine® with Dartal®

Pro-Banthine—
unexcelled for relief of cholinergic spasm—
has been combined with
Dartal—
new, well-tolerated agent for stabilizing emotions—
to provide you with
Pro-Banthine with Dartal—
for more specific control of functional gastrointestinal disorders, especially those aggravated by emotional tension.

Specific Clinical Applications: Functional gastrointestinal disturbances, pylorospasm, peptic ulcer, gastritis, spastic colon (irritable bowel), biliary dyskinesia.

Dosage: One tablet three times a day.

Availability: Aqua-colored tablets containing 15 mg. of Pro-Banthine (brand of propantheline bromide) and 5 mg. of Dartal (brand of thiopropazate dihydrochloride). G. D. Searle & Co., Chicago 80, Illinois. Research in the Service of Medicine.

SEARLE

(Continued from Page 798)

of the Center for Continuation Study provide an atmosphere especially conducive to learning.

During the 1957-58 academic year, 1,414 physicians attended twenty-two courses at the Center for Continuation Study. All but eight of these courses were intended primarily for physicians engaged in general practice. During the 1958-59 academic year, twenty-two courses, fifteen of them primarily for general physicians, have been or will be presented. Preliminary figures indicate that attendance during the current academic year will surpass that of last year. Since the fall of 1957, in addition to courses presented at the Center, Regional Seminars for physicians have been presented in Alexandria, Marshall, Fairmont, Detroit Lakes, Olivia-Redwood Falls, and Hibbing by the University in conjunction with the Minnesota State Medical Association and local medical groups.

The Department of Continuation Medical Education also is responsible for the planning and presentation of continuation courses for nurses, medical technologists, and dietitians. These programs continue to be well received.

Nursing

The provision of adequate nursing service remains a difficult problem in certain areas of the state, particularly those in which new hospitals have been constructed or existing hospitals expanded. Minnesota, however, is distinctly above the national average in the number of nurses per 100,000 population. The latest available figures indicate that 11,586 professional nurses were actively engaged in nursing in Minnesota during 1957. The Minnesota Board of Nursing issued R. N. licenses to 1658 nurses during 1958.

Eight of Minnesota's twenty-six schools of nursing have four-year degree programs, but one of these is no longer admitting students and will close in 1962. Five diploma programs will close within the next two years, but two new diploma programs opened in 1958. On January 1, 1959, total enrollment in diploma and degree programs amounted to 3597.

Practical nursing training is carried chiefly by vocational education departments of school systems in conjunction with local hospitals. On January 1, 1959, Minnesota had twenty schools of practical nursing with a total enrollment of 535. The Board of Nursing issued 743 L.P.N. licenses during 1958. A new development in Minnesota is the preparation of non-professional nursing personnel for the care of psychiatric patients.

Education for advanced professional nursing—administrative, teaching, supervisory, and public health nursing—is centered in the University of

in the depressed, unhappy patient

PROMPTLY IMPROVES MOOD

without excitation

- **Acts fast to relieve depression and its common symptoms:** sadness, crying, anorexia, listlessness, irritability, rumination, and insomnia.
- **Restores normal sleep**—without hang-over or depressive aftereffects. Usually eliminates need for sedative-hypnotics.

EFFICACY AND SAFETY CONFIRMED IN OVER 3,000 DOCUMENTED CASE HISTORIES.[1,2,3]

Dosage: Usual starting dose is 1 tablet q.i.d. When necessary, this dose may be gradually increased up to 3 tablets q.i.d.

Composition: Each light-pink, scored tablet contains 1 mg. 2-diethylaminoethyl benzilate hydrochloride (benactyzine HCl) and 400 mg. meprobamate.

(Continued from Page 800)

Minnesota which trains more teachers of nursing than any other institution in the country.

Rural community nursing is a part of the basic educational program of many schools of nursing in Minnesota. Experience for students is provided through affiliation with community hospitals outside the metropolitan areas of the state. Schools of nursing in Minneapolis, St. Paul, and Duluth assign students to community hospitals in Bemidji, Benson, Fairmont, Grand Rapids, Hibbing, Litchfield, Pipestone, Sauk Centre, Sleepy Eye, Stillwater, Thief River Falls and Worthington. The University of Minnesota provides the direction and co-ordination of this program.

Special educational nursing services in the state include extension classes, workshops, and institutes. Since 1951, the Minnesota State Nurse Scholarship Act has provided more than 1,851 scholarships.

Medical Technology

Although in the past few years the number of students completing requirements for the four-year degree program in Medical Technology has been below normal, the present indication of slight increases in the number of students in this program is encouraging. The present senior class has twenty-five students and the anticipated figure for next year is thirty.

The increasing need in the state for the services of the professional graduate Medical Technologist serves to emphasize the present critical shortage of laboratory personnel. Continued and vigorous efforts toward recruitment of students are urgently recommended.

Laboratory Aide Program

The Laboratory Aide program continues to expand. Currently, twenty-three hospitals, eleven of them outside the Twin Cities, provide clinical training for students. Since its inception in 1953, eighty-seven students have been graduated from this course, and forty-two will be graduated during 1959.

General awareness of the Laboratory Aide Program appears to be increasing, and enrollment in it may be expected to rise. Future expansion of the program should be contemplated if necessary financial support is available.

Acknowledgment

I am deeply indebted to Dr. Helen L. Knudsen, Director, Division of Hospital Service, State of Minnesota Department of Health; Miss Ruth Hovde, Associate Director, Medical Technology, University of Minnesota and Miss Leonora Collatz, Executive Secretary, Minnesota Board of Nursing, for the information they provided for this report.

in Rheumatoid Arthritis

*Using combined drug therapy with PLAQUENIL® or Aralen® as maintenance therapy. With Plaquenil or Aralen alone 62% grade I and II improvement. (Scherbel, A.L.; Harrison, J.W., and Atdjian, Martin: Cleveland Clin. Quart. 25:95, April, 1958. Report on 805 patients with rheumatoid arthritis or related diseases.)

Reasons for Failure:

1. Treatment discontinued too soon (percentage of patients improved increases substantially after first six months).
2. Patients in relapse after prolonged steroid therapy are resistant to Plaquenil or Aralen treatment for several months.

Plaquenil sulfate is supplied in tablets of 200 mg., bottles of 100.

Dose: Initial — 400 to 600 mg. (2 or 3 tablets) daily.
Maintenance — 200 to 400 mg. (1 or 2 tablets) daily.

Write for Booklet.

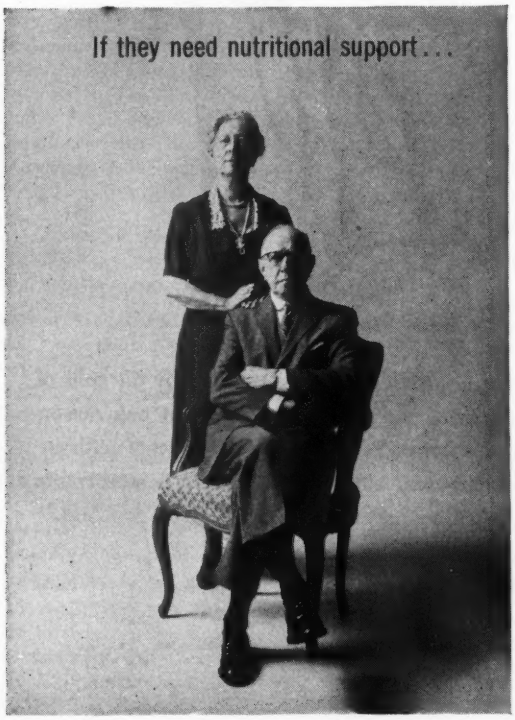
COURSE IN CONDUCT OF LABOR AND DELIVERY

The Woman's Hospital Division of St. Luke's Hospital in New York City offers a one-week course in "The Conduct of Labor and Delivery." This is for general practitioners and thirty hours Category I credit is allowed by the American Academy of General Practice.

The course consists of lectures, demonstrations, work in the Prenatal and Postpartum Clinics and assistance in the Delivery Room. Enrollment is limited as to numbers. If interested, please write to Mr. Carl P. Wright, Jr., Director, Woman's Hospital, 141 West 109th Street, New York City, for prospectus and details. The time of the course is October 8 through October 14, 1959. Enrollment will close on September 15, 1959.

ARTHRITIS AND RHEUMATISM FOUNDATION AWARDS

The Arthritis and Rheumatism Foundation offers predoctoral, postdoctoral and senior investigatorship awards in the fundamental sciences related to arthritis for work beginning July 1, 1960. Deadline for applications is October 31, 1959.



These awards are intended as fellowships to advance the training of young men and women of promise for an investigative or teaching career. They are not in the nature of a grant-in-aid in support of a research project.

The program provides for three awards:

Predoctoral Fellowships are limited to students who hold a bachelor's degree. Each applicant studying for an advanced degree must be acceptable to the individual under whom the work will be done. These Fellowships are tenable for one year, with prospect of renewal. Stipends range from $1500 to $3000 per year, depending upon the family responsibilities of the Fellow.

Postdoctoral Fellowships are limited to applicants with the degree of Doctor of Medicine, Doctor of Philosophy —or their equivalent. These Fellowships are tenable for one year, with prospect of renewal. Stipends range from

ARTHRITIS AND RHEUMATISM FOUNDATION AWARDS

(Continued from Page 806)

$4000 to $6000 per year, depending upon the family responsibilities of the Fellow.

Senior Investigator Awards are made to candidates holding or eligible for a "faculty rank" such as Instructor or Assistant Professor (or equivalent) and who are sponsored by their institution. Stipends are from $6000 to $10,000 per year and are tenable for five years.

A sum of $500 will be paid to cover the laboratory expenses of each postdoctoral fellow and senior investigator. An equal sum will be paid to either cover the tuition expense or laboratory expenses of each predoctoral fellow.

For further information and application forms, address the Medical Director, Arthritis and Rheumatism Foundation, 10 Columbus Circle, New York 19, New York.

AMERICAN UROLOGICAL ASSOCIATION AWARD

Urology Award—The American Urological Association offers an annual award of $1,000 (first prize $500, second prize $300 and third prize $200) for essays on the result of some clinical or laboratory research in urology. Competition is limited to urologists who have been graduated not more than ten years, and to hospital interns and residents doing research work in urology.

The first prize essay will appear on the program of the forthcoming meeting of the American Urological Association, to be held at the Palmer House, Chicago, Illinois, May 16-19, 1960.

For full particulars, write the Executive Secretary, William P. Didusch, 1120 North Charles Street, Baltimore, Maryland. Essays must be in his hands before December 1, 1959.

AWARDS FOR OBSTETRIC PAPERS

The Junior Fellow Division of District VI of The American College of Obstetricians and Gynecologists is offering one $100 First Award and one $50 Second Award for the best original investigative or clinical work in the field of gynecology, and a $100 First Award and a $50 Second Award for the best original investigative or clinical work in this field of obstetrics. Papers may be submitted by any resident in an accredited hospital within the confines of District VI, i.e., Illinois, Minnesota, Iowa, Nebraska, North Dakota, South Dakota, Wisconsin, and Manitoba and Saskatchewan, Canada.

For consideration for a prize this year, the papers must be received before August 1, 1959. They must be submitted in triplicate, without author identification on any copy. A covering identifying letter should be addressed to: Roger D. Kempers, M.D., Secretary-Treasurer, District VI Junior Fellow Division, Mayo Foundation, Rochester, Minnesota.

Woman's Auxiliary

HENNEPIN COUNTY AUXILIARY ELECTS OFFICERS

Mrs. Frederick G. Gunlaugson was elected president of the Woman's Auxiliary to the Hennepin County Medical Society at its annual meeting held recently at the Wayzata Country Club.

Also elected were: Mrs. Robert O. Quello, president-elect; Mrs. Sam Leonard, first vice president; Mrs. John P. Wendland, treasurer; Mrs. Henry W. Quist, Jr., assistant treasurer; Mrs. Theodore S. Smith, recording secretary; Mrs. Robert W. Goltz, corresponding secretary; Mrs. James E. Blake, auditor; and Mrs. Conrad J. Holmberg, custodian.

RAMSEY COUNTY PROJECTS HAVE YOUTH EMPHASIS

Salute to Youth Day.—The Ramsey County Auxiliary participated in the "Salute to Youth Day" recently, sponsored by the Inter Club Council of St. Paul. Outstanding and deserving students of the high schools were chosen to be honored.

Robert Kelsey, son of Dr. and Mrs. C. M. Kelsey, was the student selected by the Ramsey County Medical Auxiliary to be honored. Robert has been a leader in the Boy Scouts for many years. He is an Eagle Scout and, in 1956, attended a Boy Scout Rally in England.

In the past year, as a senior, Robert did a study on Salk vaccine for the Science Fair. Robert will attend Carleton College and plans to study medicine.

The Ramsey County Medical Auxiliary has been very happy to participate in both of these programs benefiting the youth of our country.

"Careers—See it In Action" Day.—The Woman's Auxiliary to the Ramsey County Medical Society co-sponsored with the Altrusa Club of St. Paul, a "Careers—See It In Action" day at the University of Minnesota. Senior students of the St. Paul high schools were transported to the University where they visited the hospitals and other medical facilities. The students had the opportunity to learn, at first hand, more about medical education and the allied fields which are offered at the University of Minnesota.

RENVILLE-REDWOOD OBSERVES TWENTY-FIFTH ANNIVERSARY

The Renville-Redwood County Medical Auxiliary celebrated its Twenty-Fifth Anniversary on April 30 at Olivia, Minnesota. Members of the surrounding county auxiliaries were their guests at a bridge luncheon. A highlight of entertainment was a style show consisting of clothes from the era of the organization's beginning and modeled by the auxiliary's own members.

Charter members who were present and honored with corsages were Mrs. W. Dummer, Fairfax; Mrs. R. Billings, Franklin; Mrs. G. Mesker and Mrs. J. A. Cosgriff, Sr., from Olivia. Those not present but honored with flowers were Mrs. John Dordal, Sacred Heart, and Mrs. Arthur Fawcett, of Renville.

The doctors of the Renville-Redwood Medical Society added to the festivity by presenting their wives with red roses.

Mrs. James Cosgriff, Sr., and Mrs. Harvey Knoche were in charge of arrangements.

WASHINGTON COUNTY MEETS

Members of the Washington County Medical Auxiliary, at their April meeting, were urged to bring contributions of any kind and medical magazines, to be sent to hospitals and clinics in the United States and foreign countries. The Auxiliary met at the home of Mrs. George Mitchell for a 1:30 p.m. luncheon.

Communications

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

"CAUTION"

According to the *New York Daily Mirror:* "The government today warned wearers of contact lenses to beware of current stocks of a cleaning fluid called Barnes-Hind Wetting Solution." It was stated that some of the fluid is contaminated and could cause blindness in persons with injured or infected eyes. Supplies have been recalled by the manufacturer. Replacement supplies will be available soon. Druggists have been advised to discontinue selling current stocks of this product and return unsold stocks to Barnes-Hinds Ophthalmic Products, Inc., 895 Kifer Road, Sunnyvale, California, for replacement.

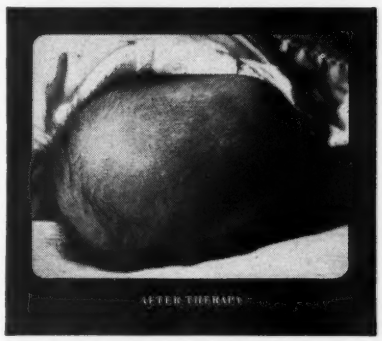
ANTI-SEBORRHEIC FOR CRADLE CAP



SOROPON™

PEDIATRIC SOLUTION

CONTAINS CERAPON-C* 12.0% IN PROPYLENE GLYCOL WITH PARABENS 0.1% AND TYROTHRICIN 0.1%. PURDUE FREDERICK *BRAND OF TRIETHANOLAMINE POLYPEPTIDE COCOATE-CONDENSATE

Specifically prepared for safe, effective removal and prevention of cradle cap, by combining unique proteo-lipid sebulytic effect with anti-infective action.

Bialkin, G.: Scientific Exhibit, American Academy of General Practice, San Francisco, April 6-9, 1959.

CASE HISTORY: J. D., a 5 month old white male developed a dry seborrhea capitis at approximately 6 weeks after birth which covered the whole scalp. By the time of examination, the child had been treated with various detergent ointment and lotion preparations without apparent effect. 'Soropon' Pediatric Solution was applied as a shampoo, directly to the scalp to remove the encrustations. A lanolin ointment was applied to scalp because of inherent dryness. A series of 5 treatments was required for complete removal and after this treatment period the seborrheic eczema had virtually disappeared. The patient has been symptom free since then.

Bialkin, G.: A New Anti-Seborrheic Agent in Pediatric Practice. Arch. of Ped. (to be published).

SUPPLY: 'Soropon' Pediatric Solution is available in bottles of 4 oz.

The Physician's Diary

Dr. Alan M. McKaig, resident physician with the Red Lake Falls Clinic since August, 1950, announced recently that he would be leaving that city for the practice of medicine at Chenango Bridge, New York. Dr. McKaig will join a clinic there and specialize in obstetrics.

* * *

Open House was recently held at the new $400,000 Austin Clinic. It was opened March 2—forty years after four doctors first associated themselves in medical practice as the Austin Clinic. The original clinic staff, Dr. C. F. Lewis, Dr. C. C. Allen, Dr. E. C. Rebman, and Dr. W. B. Grise, are deceased. Dr. Grise participated in the planning, but died before the opening. The new building has office space for the fourteen doctors now on the staff. Present members of the staff include: **Drs. David P. Anderson** and **Harold J. Anderson,** surgeons; **Thomas M. Serry** and **John D. Hagan,** internal medicine; **L. G. Flanagan,** eye, ear, nose and throat; **E. C. Sargeant,** gynecology-obstetrics; **Wallace R. Anderson,** pediatrics; **F. H. Rosenthal, Robert R. Wright, H. P. Van Cleve, Inman A. Hesla** and **Harold E. Paulus,** general medicine; and **Stanley C. Peterson** and **John C. Todd,** consulting radiologists.

Members of the Mayo Clinic who have participated in recent meetings throughout the United States and Brazil include the following: **Dr. H. F. Polley** presented two papers at meetings in Rio de Janeiro, Brazil. He spoke on "The Development and Use of Steroids in Rheumatic Diseases," before the Academia Brasileira de Medicina, and read a paper, "Early Diagnosis and Current Treatment of Rheumatoid Spondylitis" at a meeting of the Sociedade Brasileira de Rheumatologia. He also participated in a round table discussion on "Dexamethasone and Steroids in General" at a meeting of the society. He presented a paper, "Current Use of Steroids in the Management of Rheumatoid Arthrutic" at a meeting of the Isthmian Medical Society in Panama City, Panama. **Dr. C. W. Mayo** presented a paper, "Survival in Carcinoma of the Rectum and Tectosigmoid: A Comparison of Operative Procedures," at a meeting of the Phi Beta Pi Alumni Association in Pittsburgh. **Dr. T. T. Myers** presented a paper at the Sectional Meeting of the American College of Surgeons in Vancouver, Washington. His paper was entitled "Is Major Surgery Necessary in the Treatment of Varicose Veins?" **Dr. H. L. Williams** attended meetings of the American Otological Society, the American Laryngological Society and the Triologi-

the "full-range"

Dr. Alfred Uihlein, neuro-surgeon at the Mayo Clinic, is currently in Europe where he is participating in a panel discussion sponsored by the Latin-Mediterranean Surgical Association. Then at Padua he will speak at the University on invitation of Dr. Piero Frugoni, who was a fellow in surgery in the Mayo Foundation from 1936-40 and is now clinical professor of neurologic surgery in the University of Padua. In Zurich, Dr. Uihlein is scheduled to speak before the medical students of the University. He will also deliver the MacArthur Postgraduate Lecture in Edinburgh, Scotland.

* * *

Dr. John J. Catlin, of Buffalo, was honored for his more than fifty years of service to that community and area in a special "King for a Day" program held at Buffalo recently. Dr. Catlin received the key to the city in the morning, and was guest of honor and principal subject at the program at school in the evening. Several speakers recalled the many events which highlighted his life's work in Buffalo. He was saluted for his activity in civic affairs as well as his career service with the American Legion and the Tuberculosis Association.

* * *

Dr. Frank H. Krusen, senior consultant in physical medicine of the Mayo Clinic and professor of physical medicine and rehabilitation, Mayo Foundation, will be the principal speaker at the dedication of the Gottsche Rehabilitation Center at Thermopolis, Wyoming, in the very near future.

* * *

Physicians of the Park Region Medical Association and lawyers of the Seventh Judicial District attended a legal-medical institute at Alexandria recently. The interprofessional group was addressed by Charles Murnane, St. Paul trial lawyer, and **Dr. Gordon Kamman,** St. Paul psychiatrist. Arrangements for the meeting were made

DBI (N¹-β-phenethylbiguanide HCl) is an entirely new oral hypoglycemic compound, different in chemical structure, mode of action, and in spectrum of activity from the sulfonylureas. DBI is usually effective in low dosage range (50 to 150 mg. per day).

"full-range" hypoglycemic action — DBI lowers elevated blood-sugar and eliminates glycosuria in **mild, moderate** and **severe** diabetes mellitus...

brittle diabetes, juvenile or adult—DBI combined with injected insulin improves regulation of the diabetes and helps prevent the wide excursions between hypoglycemic reactions and hyperglycemic ketoacidosis.

stable adult diabetes — satisfactory regulation of diabetes is usually achieved with **DBI** alone without the necessity for insulin injections.

juvenile diabetes — DBI often permits a reduction as great as 50 per cent or more in the daily insulin requirement.

primary and secondary sulfonylurea failures — DBI alone, or in conjunction with a sulfonylurea, often permits satisfactory regulation of diabetes in patients who have failed to respond initially or who have become resistant to oral sulfonylurea therapy.

smooth onset — less likelihood of severe hypoglycemic reaction — DBI has a smooth, gradual blood-sugar lowering effect, reaching a maximum in from 5 to 6 hours, and a return to pretreatment levels usually in 10 to 12 hours.

safety — daily use of DBI in therapeutic dosage for varying periods up to 2½ years has produced no clinical toxicity.

side reactions — side reactions produced by DBI are chiefly gastrointestinal and occur with increasing frequency at higher dosage levels (exceeding 150 mg. per day). Anorexia, nausea or vomiting may occur — but these symptoms abate promptly upon reduction in dose or withdrawal of DBI.

supplied — DBI, 25 mg. scored, white tablets — bottle of 100.

IMPORTANT — before prescribing DBI the physician should be thoroughly familiar with general directions for its use, indications, dosage, possible side effects, precautions and contraindications, etc. Write for complete detailed literature.

Improved ULVICAL®

the preferred prenatal supplement is now even better!

TETANY OVERCOME

Tetany due to calcium deficiency is usually overcome within 24 hours.

OPTIMAL HEMOGLOBIN LEVELS

May be obtained in spite of subacidity or achlorhydria.

MORE EASILY TOLERATED

Ulvical supplies all necessary supplemental factors without discomfort of intolerance.

Ulvical® (Ulmer) assures these modern ladies-in-waiting of a generous amount of iron and calcium plus the recognized prenatal vitamins . . . in a small tablet . . . especially designed for rapid assimilation and easy toleration.

For maximal utilization . . . timed release of these essentials is accomplished by special coatings controlled to dissolve at the pH of the stomach, duodenum and jejunum.

Important, too, calcium pyrophosphate contains larger amounts of elementary calcium which is quickly metabolized to increase plasma blood levels. Leg cramps are quickly relieved; small daily doses sustain this relief.

Each tablet contains:

Calcium Pyrophosphate (Ca 150 mg., P 120 mg.), 7½ gr.
Ferrous Sulfate USP (Fe 38 mg.) 3 gr. 3.8 M.D.R.
Vitamin A (Ester) 1500 USP Units ⅜ M.D.R.
Vitamin D (Irradiated Ergosterol) 200 USP Units ½ M.D.R.
Thiamine Mononitrate (B_1) 1 mg. 1 M.D.R.
Riboflavin (B_2) .... 2 mg. 2 M.D.R.
Ascorbic Acid (C) 16.66 mg. ½ M.D.R.
Vitamin E .....2.2 I.U.* (from d alpha tocopheryl acetate N.F.)

M. D. R. — Minimum Daily Requirement. *M.D.R. not established.
Dose: One or two tablets three times a day.

Public Health

SUFFOCATION HAZARDS OF PLASTIC MATERIALS

Members of the Minnesota State Medical Association are encouraged to co-operate in a program of public health education against suffocation due to a soft plastic bag of the type commonly used in commercial dry cleaning, food and household product packaging. According to Minnesota State Department of Health statistics, thirty-five suffocation deaths from plastic materials of this type have been reported by state health departments across the nation. In Minnesota, three deaths have been reported in this same period. A fourth death from plastic suffocation was recorded on Christmas Eve.

All of Minnesota's plastic deaths were in infants from two to four months of age. All of the deaths could have been prevented if the danger of this new plastic material could have been known by the parents. There should at least be a warning printed on the plastic informing parents of the danger to infants. Elsewhere in the nation, deaths have been reported in older youngsters who were accidentally suffocated while playing with the plastic over their heads. At least thirty-five such incidents have been reported in the United States since January 1, 1959,; the total for two years is more than fifty-five.

While the use of any plastic sheeting on cribs is potentially hazardous, the soft flimsy type now found on so many household products and on dry-cleaning is particularly so. Apparently, an electrostatic charge is easily generated by the mere friction of handling the soft, pliable material. Thus when the youngster moves around on the plastic in the crib or plays with it, it is quickly attracted to his face where it stubbornly molds itself over his nose and mouth cutting off the air. In spite of its thinness, the plastic does not tear readily when the child fights to get it off. Unless an adult comes to the child's rescue, death can ensue in a few minutes from suffocation.

According to Dr. A. B. Rosenfield, Director of the Division of Special Services of the Minnesota Department of Health, every year in Minnesota, approximately twenty-five infant deaths are reported due to "mechanical suffocation in crib or cradle." Autopsies have revealed, however, that many of these are actually the result of a respiratory infection believed to be caused by a virus. Often an apparently healthy baby is found dead under tossed bedclothing, and parents mistakenly conclude that the "accident" resulted from their negligence, whereas, death was probably caused by an infection and could not have been prevented.

In all infant deaths attributed to suffocation, it is essential that an autopsy be performed to determine whether death was due to suffocation or infection. If possible, the autopsy should be performed by a pathologist who is familiar with infant diseases.

Some precautions recommended to prevent accidental suffocations in children and infants are:

1. Do not use pillows in cribs—infants do not need them.
2. Do not use sheets of thin plastic material—such as bags from dry cleaning—as homemade covers for crib mattresses or sofa pillows.
3. Never allow children to play with plastic bags or coverings, and keep them out of their reach just as you would sharp knives or poisons.
4. Be sure that crib mattresses are firm and fill the crib completely—babies can smother in the space between the edge of the mattress and the crib ends.
5. Crib slats should be close together so that the baby cannot get his head between them and strangle.

A leaflet on helpful hints to parents on the correct use and misuse of plastic film is available in quantity, free of charge, from the Society of the Plastics Industry, Inc., 250 Park Avenue, New York 17, New York; or from the Minnesota State Medical Association, 496 Lowry Medical Arts Building, St. Paul 2, Minnesota.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

NOW OR NEVER. The Promise of the Middle Years. By Smiley Blanton, M.D., with Arthur Gordon. 275 pages. Price, $4.95. Englewood Cliffs, New Jersey: Prentice-Hall, 1959.

Written by a practicing psychiatrist for people between the ages of thirty-five and sixty, this book is designed for all the troubled, anxious people of middle age, who could be given self-knowledge and through the resulting insights be able to live full, happy lives.

Dr. Blanton is a Diplomate of the American Board of Psychiatry and Neurology. His work is centered in the American Foundation of Religion and Psychiatry, of which he is associate founder and director, and with the Religio-Psychiatric Clinic of the Marble Collegiate Church, of which he is director. By means of the case histories of those who have consulted him through these two avenues, particularly the former, he illustrates why many middle-aged people fail to live happy, satisfying, anxiety-free lives.

In the chapter, "Alcohol—Friend or Foe," he reiterates what he calls the theme of the book: The energy of youth enables the adolescent to build up defenses against hidden fears and anxieties, but as middle age approaches, his defenses weaken, and often the emotional tensions, which have been growing since childhood, will break through with results ranging from irritability or moodiness to a complete mental "breakdown." Not all middle-aged people require expert medical help. Some have developed an emotional maturity which enables them to tolerate anxiety. Many less fortunate ones, however, probably because of the way they were handled as children, find themselves beset with tensions and unconscious anxieties to the point where relief must be found.

Each chapter discusses an area where tensions are most likely to develop: marriage, children, work, money, the body, alcohol, sex, religion, aging parents, facing old age, and personality integration. Those who come to the Foundation for help gain understanding through psychotherapy of the causes of the difficulties and, hence, discover the solution to their problems.

Psychiatrists will surely find the book not only helpful but very interesting. Unfortunately, it contains no index and almost no bibliography.

YOUR MIND CAN MAKE YOU SICK OR WELL. Curt S. Wachtel, M.D. 244 pages. Price $4.95, cloth. Englewood, New Jersey: Prentice-Hall, Inc., 1959.

PATIENT CARE AND SPECIAL PROCEDURES IN X-RAY TECHNOLOGY. Carol Hocking Vennes, R.N., B.S., formerly Surgical Supervisor and Clinical Instructor, University of Minnesota Hospitals, Minneapolis, Minnesota, and John C. Surgery of the Spleen

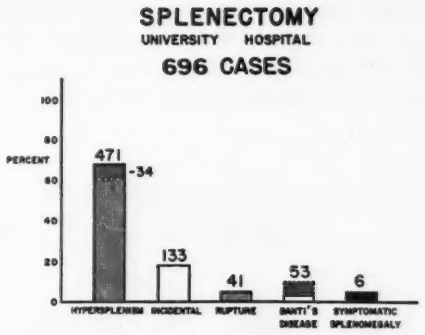

Fig. 1. Indications for splenectomy. Note that thirty-four cases are shown in both the hypersplenism and portal hypertension (Banti's disease) columns since there were two indications for splenectomy.

Splenectomy can be a life-saving procedure. 696 splenectomies were performed with a mortality of 1.9 per cent when the operation has been done for primary hypersplenism, but it increases to 13.6 per cent in those patients who have hypersplenism secondary to another disease. Splenectomy performed incidentally to other major upper abdominal surgery apparently does not increase the mortality in these cases. The use of ACTH and cortisone in hypersplenism has not removed nor reduced the need for splenectomy.

ROBERT M. ZOLLINGER, M.D.,
and ROGER D. WILLIAMS, M.D.
Columbus, Ohio

From the Department of Surgery, The Ohio State University Medical Center, Columbus, Ohio.

A BETTER knowledge of the physiology of the spleen in relation to certain blood dyscrasias and portal hypertension has increased the number of splenectomies performed during recent years. The number of splenectomies varies according to the interests of hematologists, internists and surgeons in a given area. Surgeons, however, must be familiar with the various indications for splenectomy and the problems they present before, during, and after operation. This is a report of the indications for splenectomy and results of surgery in a university medical center.

During the twelve year period ending June 30, 1958, 696 splenectomies were performed at the University Hospital. Figure 1 shows the indications for splenectomy in the order of their frequency. Hypersplenism was the most common indication due to the interests of our hemotologists. Thirty-four patients are included in both groups of hypersplenism and Banti's disease. Thus, there were two indications for splenectomy in these patients. Removal of the spleen in combination with either the stomach, pancreas or colon for either benign or malignant disease or in the occasional case when the splenic capsule was torn during another operative procedure has been our

second most common indication for splenectomy. We have grouped these cases under "incidental splenectomy." Our experience with traumatic rupture of the spleen has been limited but this should not imply that rupture is an uncommon indication for splenectomy.

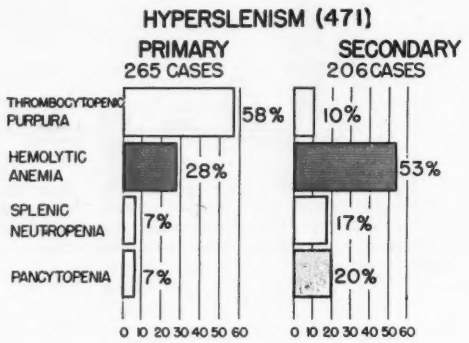

Fig. 2. Of the various cytopenics due to hypersplenism requiring splenectomy, hemolytic anemias are the most common (this includes acquired hemolytic anemia).

Hypersplenism

Figure 2 shows the incidence of the various cytopenias in 471 cases of hypersplenism. Idiopathic (primary) thrombocytopenic purpura has been the most common indication for splenectomy. Hemolytic anemias, both primary and secondary, apparently exceed thrombocytopenic purpura in frequency. In this series of cases those patients with idiopathic acquired hemolytic anemia have been grouped with the secondary hemolytic anemias, accounting for the increase in the latter.

Hypersplenism is a term used to describe an overactivity of the spleen which results in a decrease in one or more of the formed elements of the peripheral blood.[1] Whether the mechanism responsible for this hyperfunction is increased phagocytosis within the spleen or the production of a substance by the spleen which acts on the bone marrow or peripheral blood is a subject of continued investigation by hematologists.[2,3,4] Regardless of the basic mechanism involved, several clinical entities result, depending upon the deficient peripheral blood element. In addition, these diseases may be further divided into primary hypersplenism when of unknown cause and secondary hypersplenism when hyperfunction of the spleen occurs as a complication of another chronic systemic disease.

A decrease in blood platelets due to splenic overactivity unassociated with another disease process produces the disease known as idiopathic thrombocytopenic purpura. Primary or idiopathic hypersplenism involving the red cells leads to congenital hemolytic anemia (icterus). The decrease of white cells has been termed primary splenic neutropenia,[5] and when all three elements are involved, primary splenic panhematopenia.[6] The differential diagnosis in this group of diseases must be made by hematologists through a comparison of peripheral blood changes with bone marrow response.

The same cytopenias occur in secondary hypersplenism but the splenic overactivity is associated with another chronic disease. Figure 3 shows the chronic disease with which secondary hypersplenism developed as a complication. This secondary hypersplenism more often develops in patients with leukemia, a lymphoma, or some chronic infection such as tuberculosis. In addition, we have included as secondary hypersplenism forty-five patients with acquired hemolytic anemia and eight patients with Felty's syndrome although the primary systemic disease is not clearly defined.

The diagnosis of hypersplenism must be made by a competent hematologist if the results of surgery are to be good. Splenic enlargement is variable, being noted in nearly all patients with hemolytic anemia and all forms of secondary hypersplenism. It is so rare with idiopathic thrombocytopenic purpura that when noted it should suggest that the purpura is actually due to secondary hypersplenism. Bone marrow study is mandatory. A peripheral blood cytopenia is associated with an hyperplasia of the specific element(s) of the blood being destroyed. Special tests, such as the Coomb's hemagglutinin test and the determination of osmotic fragility, are important in determining whether an hemolytic anemia is of the acquired type. Lymph node biopsy, liver biopsy, or barium swallow may be helpful in determining other diseases when secondary hypersplenism is suspected.[7]

The results in the treatment of hypersplenism will depend on a correct diagnosis followed by close attention to pre and postoperative care and

a careful splenectomy. Whereas excellent results and a high cure rate follows splenectomy for primary hypersplenism, the immediate good hemotological results in secondary hypersplenism do not effect the course of the associated disease. Special factors in the preoperative preparation of patients with different forms of hypersplenism should be considered.

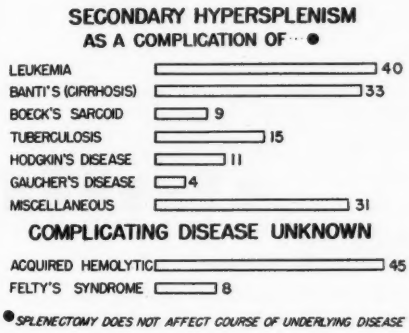

Fig. 3. The chronic diseases during the course of which secondary hypersplenism develops and the number of cases of each are listed. Splenectomy improves only the hematological state.

Preoperative Preparation

Thrombocytopenic Purpura.—The marked hemorrhagic tendency in thrombocytopenic purpura has suggested that these patients would benefit from fresh whole blood transfusions or from platelet transfusions. Nearly 50 per cent of our patients have had platelet counts below 10,000 and many have had spontaneous gastrointestinal or cerebral hemorrhage. Although blood platelet levels will be temporarily elevated with fresh blood, measurement of blood volume in a number of these patients has shown an average of over 1500 cc. volume deficits which suggest that volume replacement might be just as important as platelet replacement (Fig. 4). The frequently rapid rise of platelet levels following the use of ACTH or cortisone may therefore give a false sense of security when actually a blood volume deficit still persists.

Since these patients have a marked hemorrhagic tendency, naso-gastric intubation prior to surgery is not utilized. In addition, the anesthetist should be hesitant to use endotracheal intubation since oral-tracheal hemorrhage may produce marked respiratory embarrassment. This means that these patients should be at least 8 hours without food so that vomiting during the operative procedure

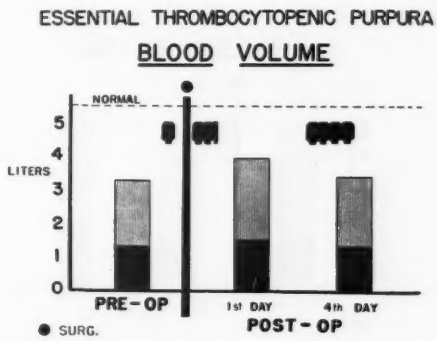

Fig. 4. The average blood volume values in eight cases of essential (primary) thrombocytopenic purpura are shown. Note the marked deficit in both red cell mass (black) and plasma volume (striped) and the average number of transfusions required (black "bottles," each equals 500 cc. whole blood).

or anesthetic recovery is not likely to occur. Although several years ago emergency splenectomy in those patients manifesting neurological symptoms was occasionally indicated, ACTH and cortisone have made possible the delay in most patients so that an elective splenectomy can be performed.

Hemolytic Anemia.—Splenectomy is often recommended in patients with hemolytic anemia despite an alarming anemia. Nearly half of our patients have had pre-operative red cell counts below 2.5 million and hemoglobin levels below 10.0 grams which are well below the usually accepted safe levels for elective major surgery. Many of these patients, however, have already had a hemolytic crisis and since preoperative blood transfusions usually increase hemolysis and may further precipitate another crisis, the hematologist may consider transfusion contraindicated. Although blood volume measurements have shown a marked deficit in red cell mass in these patients (Fig. 5) there is usually a compensatory increase in the plasma volume so that if adequate oxygen is given during anesthesia they will tolerate surgery well. These patients should therefore be ambulatory with an adequate vital capacity prior to elective

splenectomy. Ligation of the splenic artery as an initial step prior to surgery makes possible the giving of necessary transfusions during the operative procedure.

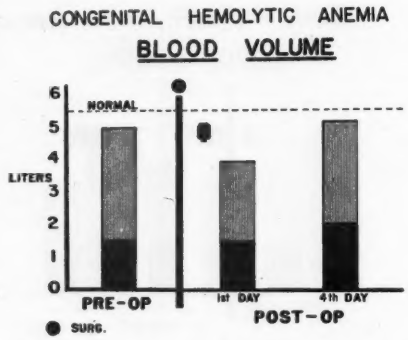

Fig. 5. Note that despite a marked deficit in red cell mass (black) there is a compensatory increase in plasma volume (striped). Adequate oxygen during anesthesia permits safe surgery without preoperative transfusions.

Splenic Neutropenia and Panhematopenia.—Blood volume deficits have also been noted in patients with splenic neutropenia and panhematopenia. However, the indications and contraindications to transfusions in this group will be determined by the hematologist. Every effort should be made to correct infections in patients with splenic neutropenia; this may require preoperative antibiotics. Since the splenic neutropenia frequently leads a cyclic course, splenectomy is often delayed until a time when the white count is at its highest peak.

A number of patients with splenic neutropenia or secondary hemolytic anemia have in addition had cirrhosis of the liver with portal hypertension. If esophageal varices exist the same precautions with naso-gastric intubation are carried out as followed in those patients with thrombocytopenic purpura. In all patients, prothrombin levels should be brought to the highest possible value with the use of parenteral vitamin K.

ACTH and Cortisone.—When adrenocorticotropic hormone (ACTH) and cortisone became available in early 1950 for the treatment of various hematological disorders, it was considered that there would be a change in the indications for splenectomy for hypersplenism. Figure 6 shows that despite the utilization of these drugs in a large number of our cases, the average yearly number of splenectomies for hypersplenism remains

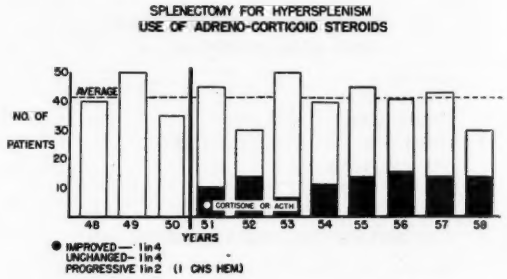

Fig. 6. The number of patients receiving steroid therapy are shown in black. The relatively poor response has not encouraged our hematologists to rely on these drugs in preference to splenectomy in most patients with hypersplenism.

unchanged. The decrease in 1951 is probably due to the temporary results of these medications. Unfortunately, the recurrence of purpura, neutropenia, and hemolytic anemia after discontinuance of these drugs is common. A recent evaluation by Doan, Bouroncle and Wiseman[8] of the results in cases treated with ACTH and cortisone has shown a two-fold increase in postoperative complications when surgery follows their use. They, therefore, hesitate to use steroids without great care and discrimination in patients with a classical hypersplenic cytopenic syndrome.

In some cases of hypersplenism ACTH and cortisone give dramatic remissions and for this reason their value in preparing patients for surgery must be considered in poor risk patients. They usually make possible the delay of surgery until the patient is in the best possible condition. Finally, when splenectomy fails, particularly in patients with acquired hemolytic anemia or thrombocytopenic purpura, these drugs should certainly be tried.

Operative Considerations

Splenectomy should be carried out utilizing a meticulous technique with individual ligation of bleeders and firm compression of wound edges to prevent oozing during the operative procedure. Early ligation of the splenic artery has been carried

out in all the elective splenectomies for hypersplenism since this usually makes possible the giving of whole blood transfusions to patients with hemolytic anemia and may dramatically decrease the oozing tendency of those patients with thrombocytopenic purpura. In addition, subsequent blood loss during the course of splenectomy is usually decreased. Great care should be taken to prevent injury to the tail of the pancreas during the removal of the spleen, and individual ligation of the vessels of the splenic pedicle should be carried out. The splenic vein is usually the last of these vessels to be ligated since its identification and preservation may be important for its utilization in a spleno-renal shunt in patients with portal hypertension. At the completion of splenectomy and following a careful repeated search for accessory spleens, biopsies are routinely taken of retroperitoneal lymph nodes, liver, and mesenteric lymph nodes.[7] Those retroperitoneal nodes along the border of the pancreas are readily accessible. These biopsies have established the correct diagnosis in 22 per cent of our cases of secondary hypersplenism. Without the aid of these biopsies, which have shown on pathological examination some other chronic disease process, the diagnosis would have remained one of primary hypersplenism. Accessory spleens have been found in approximately 20 per cent of our patients with primary hypersplenism as compared to 16 per cent in those with secondary hypersplenism.

The surgical risk in primary hypersplenism is less than that in secondary hypersplenism. The mortality in primary hypersplenism has been only 1.9 per cent. Poor liver function, chronic diseases with poor nutrition, lowered vital capacity and the increased age of the patients with secondary hypersplenism have increased the mortality in this group to 13.6 per cent.

Postoperative complications have been twice as common in patients with secondary hypersplenism. Pulmonary complications and postoperative bleeding, either intra-abdominal, into the wound or from the varices, have been the most common complications and accounted for a majority of the deaths. Cerebral hemorrhage, present before surgery in a few patients with purpura, has been a cause of death in one patient. Pancreatitis may present a serious problem following splenectomy, so that great care should be taken to prevent pancreatic injury during splenectomy. Pancreatitis has accounted for two of our postoperative deaths. Leakage of pancreatic juice or the formation of a pancreatic fistula, however, has not been a problem, so that we have not drained the pancreas following splenectomy.

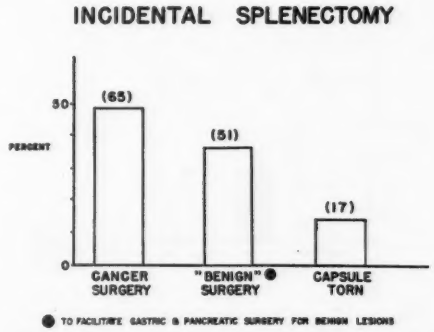

Fig. 7. The second most common indication for splenectomy is called incidental since the spleen is removed as a part of another surgical procedure.

Despite the marked rise of blood platelets following splenectomy, phlebitis or thrombo-embolism has not been a common complication. Two patients have developed mild superficial phlebitis of the lower extremities and one patient developed chest pain after discharge from the hospital, but pulmonary embolism was not proven. We, therefore, have not utilized anticoagulants prophylactically in the post-splenectomy period.

Incidental Splenectomy.—When the spleen is removed while performing another abdominal or thoraco-abdominal procedure, this may be termed "incidental splenectomy" (Fig. 7). Splenectomy in combination with radical upper abdominal surgery for cancer has become a commonly accepted procedure during recent years. This has been our most common indication for incidental splenectomy. Of 133 incidental splenectomies over half have been performed to facilitate the surgical removal of the stomach, pancreas, lower esophagus or colon for carcinoma.

Although it can be accepted that splenectomy is usually necessary when the body and tail of the pancreas are excised for benign lesions, the removal

of the spleen during subtotal gastrectomy for ulcer may not be so readily accepted. We have not hesitated to remove the spleen in these cases when this organ interferes with adequate mobilization

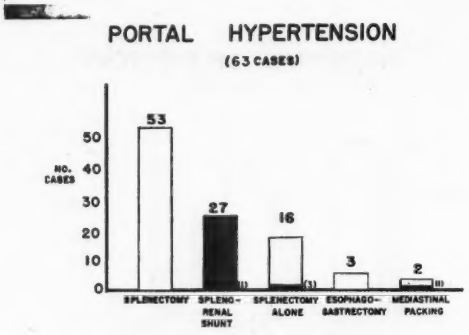

Fig. 8. The number of cases and procedures performed in sixty-three patients with portal hypertension. The figures in parentheses indicate mortality.

of the stomach or when it was considered that the spleen might, by its weight, place tension on a gastro-intestinal suture line. Adhesions of the spleen to the diaphragm may cause tears in the capsule when traction is applied to the omentum or gastric pouch during gastric resection. While performing elective gastrectomy, or in a few cases when the left colon was excised, the capsule of the spleen was torn and splenectomy became necessary.

Although the spleen can usually be readily removed while performing other major upper abdominal surgery, any change in morbidity or mortality thereby produced is of importance. A 13.5 per cent mortality was found in those patients in whom incidental splenectomy was performed. All deaths were in patients undergoing either radical gastrectomy with partial pancreatectomy or esophago-gastrectomy for cancer. It is difficult to match these with comparable cases where splenectomy was not performed since splenectomy was necessary in the more extensive cancer operations. However, no deaths and no increase in postoperative complications were noted when splenectomy was performed during elective gastrectomy or during procedures for benign disease after the capsule was inadvertently torn.

Portal Hypertension.—During recent years, a number of surgical procedures directly or indirectly associated with the spleen have been advocated in the management of portal hypertension. Fifty-three splenectomies have been performed and in thirty-three of these cases another procedure has been utilized in addition to splenectomy (Fig. 8). Splenectomy alone was performed on sixteen patients for portal hypertension and hypersplenism with one death. Either because gastrointestinal bleeding was not a problem, portal pressure was not greatly elevated, or induration of the splenic vein was great, a venous shunting procedure was not carried out in these patients.

Portocaval venous shunting procedures have become one of the most popular approaches to the treatment of portal hypertension during the past decade. For this reason we have utilized a meticulous technique of splenectomy which includes careful dissection of the hilum with individual ligation of the vessels leaving the splenic vein as the last vessel to be ligated so that it then is readily available should a splenorenal venous anastomosis be considered indicated. Portal venous pressure should be measured when hypertension is suspected. Twenty-seven splenorenal shunts have been performed with only one death (4 per cent). The majority of these patients had active hypersplenism associated with portal hypertension. In a one to seven year follow up there have been only four cases (17 per cent) with recurrent hemorrhage. Twenty (80 per cent) are living and sixteen (64 per cent) are working.

Esophagogastrectomy has been performed three times. Although these patients have done well immediately following their surgery we have not adopted this extensive procedure as the one of choice for patients with esophageal varices. Several years ago we tried mediastinal packing to control esophageal varices as advocated by Garlock;[9] however, animal experimentation in our surgical laboratory did not suggest a definite value for this procedure so that it has been discontinued.

Traumatic Rupture.—Traumatic rupture of the spleen is probably one of the most common indications for splenectomy throughout the country. Our experience, however, has been limited (Fig. 9). Our mortality may be higher than in clinics where splenic rupture is more commonly seen, but this finding has stressed, at least for us, the im-

portance of associated injuries as a cause for death in patients with rupture of the spleen. In all patients with rupture of the spleen in whom death occurred, injury to the brain, heart and lung, and abdominal viscera or multiple fractures were the most important causes of death. In a recent review of 200 patients with 273 abdominal injuries we found that multiple extra abdominal injuries were present in two out of five patients.[10] Also one out of five had more than one intra-abdominal organ injured.

With early use of whole blood transfusions and the rapid transit time of injured patients from the site of injury to a hospital emergency clinic there should be no mortality from an uncomplicated splenic rupture. However, a low mortality can be anticipated only if the diagnosis is suspected early. Shock in the patient with head injury and persisting shock after what has been considered adequate blood replacement for fractures point to internal hemorrhage. Abdominal roentgenograms are frequently of little help. When abdominal pain and tenderness exist a needle puncture paracentesis should be performed, utilizing a number 20 or number 18 gauge, long spinal needle, in the search for blood. Finally, splenectomy for splenic rupture is an inadequate operation without careful exploration for other organ injuries.

Summary

The indications for splenectomy have increased with better knowledge of normal and abnormal liver and splenic physiology. Splenectomy is indicated in the management of hypersplenism, portal hypertension and splenic rupture, and in facilitating other major abdominal surgery. The incidence of splenectomy will vary according to the interests of surgeons and hematologists in a particular area. In surgery for hypersplenism the diagnosis must be confirmed by the hematologists through study of both the peripheral blood and bone marrow. Careful pre-operative preparation of the patient is important regardless of the indication for splenectomy. Consideration must be given to the need for pre-operative correction of blood volume deficits and to the management of concommitant abnormalities, such as associated injuries with splenic rupture of chronic debilitating diseases with secondary hypersplenism. A careful technique of splenectomy should be performed which follows the principles of adequate exploration for associated injuries in cases of trauma and a meticulous technique in elective splenectomy. In the latter cases a careful search should be made for accessory spleens and the splenic vein should be dissected out for utilization in a spleno-renal shunt if portal hypertension is found.

Uniformly good results will follow accurate diagnosis combined with careful hematological evaluation, close attention to pre-operative preparation and a careful splenectomy.

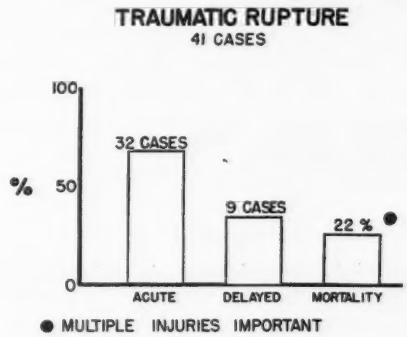

Fig. 9. Only forty-one cases of splenic rupture have required splenectomy. The high mortality is due to multiple injuries.

Air Pollution

A Public Health Problem of the Community

HAROLD J. PAULUS, Ph.D.
Minneapolis, Minnesota

Presented in symposium at the Minnesota Public Health Conference, Saint Paul, Minnesota, September 19, 1958.

THE emphasis on public health problems in a community has undergone several changes since the day of Ervin Chadwick. Treatment of a water supply, proper sewage disposal, vaccination —these and other preventive measures have changed serious problems into more or less routine procedures. Whenever it appeared in the past that most of the public health problems were under control, a different problem usually developed from our changing civilization. Such has been the recently recognized public health hazard, the pollution of the air of our communities.

We are concerned about the purity of the water, milk and beverages that we drink, the freedom from harmful bacteria and other contamination of the food we eat; the sanitation and safety of the place in which we live and work and now a concern about the air we breathe. When it is considered that breathing is a normal body function that must take place regardless of the type or amount of contamination in the air, it is only reasonable that serious thought be given to the problem from a public health standpoint. A positive answer to the question as to whether a given community has an air pollution problem may depend only on the passage of time. With the anticipated increase in industrial expansion and community growth, increased use and numbers of automobiles, buses, trucks and other means of transportation, the pollution of the air in our communities will increase substantially unless or until an adequate air pollution control program is in complete command of the situation.

Dr. Paulus is Associate Professor, School of Public Health, University of Minnesota.

Community Disasters

Pollution of the air by contaminants coming from various sources is not a new or recent problem of the community. In the thirteenth century, a law was passed in England in an attempt to control the serious nuisance of black sooty smoke caused by the combustion of a cheap coal. In the 1880's the cities of St. Louis, Cincinnati and Pittsburgh adopted ordinances in an effort to control the production of excessive smoke and its accompanying ill effects. Many other cities soon adopted smoke ordinances but industrial expansion and community growth continued the problem. It was not until well into the twentieth century that several disastrous episodes focused the world's attention on air pollution and pointed out dramatically the public health aspect of the problem. These episodes occurred in communities of varying size from a population of a few hundred to one of several million showing that this type of disaster is not selective in the number of people it may affect.

Communities along a section of the Meuse River in Belgium suffered the first noteworthy air pollution disaster in December, 1930. A heavily industrialized area was situated in a narrow valley with hills forming the valley walls. A strong temperature inversion lasting for several days provided a ceiling for the valley and helped in causing an increase in the concentration of various contaminants. The health of several thousand persons was affected with a total of sixty-three deaths attributed to this episode.

In our country, an air pollution disaster occurred at Donora, Pennsylvania, in October, 1948, with a result of twenty deaths and several thousand persons becoming ill. Donora, a community of about 12,000 people, is located in an industralized valley along the Monongahela River. As in the Belgium episode, a temperature inversion retained all the contaminants from various sources in the valley for a period of over four days. In November, 1950, Poza Rica, Mexico, a community of only a few hundred persons, was subjected to an air pollution fumigation when waste hydrogen sulfide

gas was accidentally released into the atmosphere during a period of stable weather conditions. People of all ages were affected with twenty-two deaths and many persons being hospitalized. In December, 1952, London, England, experienced a week-long fog accompanied by a strong temperature inversion which virtually gave the area a 150 foot ceiling. According to valid statistical evidence, about 4,000 deaths have been attributed to this period of London Smog. These and other episodes have several things in common both in cause and effects. Among the similarities are certain air pollution contaminants, a certain type of weather condition, and topography that lends itself to the situation. Almost any community with the right combinations of weather, contamination, and topography could be subjected to a similar occurrence.

Air Pollution Sources

In order that this public health problem of a community might be better defined from a preventive standpoint, it seems necessary to discuss briefly the sources and types of air pollution contaminants. One of the major sources results from the combustion of all kinds of fuel for the production of heat, electric power and for certain industrial operations. The combustion of coal, natural gas, and fuel oil when properly done may yield dust, flyash, sulfur dioxide, fluorine compounds and other contaminants. When the combustion is incomplete, soot, smoke, carbon monoxide (in addition to the above contaminants) are discharged into the air of the community. Incomplete combustion of gasoline and other motor fuel used in the operation of cars, buses and trucks places many different kinds of organic contaminants in the air.

Industrial operations and processes are the major sources of air pollutants in the communities in which they are located. Some examples of types of industry and a few of the contaminants they may contribute to the air pollution load are as follows: steel mill—dust, carbon monoxide, iron oxide and smoke; oil refinery—hydrocarbons, mercaptans and hydrogen sulfide; grain industry—grain dust and different odors; paper plant—sulfur compounds and odors; phosphate fertilizer plant—sulfur dioxide and fluorides; foundries—dust, iron oxide and oxides of nitrogen.

Some communities, by their own policies, may add to the air pollution problem. Communities that do not provide collection and disposal of refuse, rubbish, leaves and garbage encourage the use of backyard and home incinerators. The incinerators in use today are mostly of poor design, are poorly operated and can produce large amounts of dust, smoke, various gases and odors. Communities that do not operate a municipal incinerator or a sanitary land-fill may encourage the use of a burning dump with its continuous contribution to the air pollution load. Burning of leaves on the owners lot or in the street is another pollution problem for local community control.

Effects of Air Pollution

The effects of excessive amounts of air pollution in a community are numerous, the most important one, undoubtedly, being concerned with the health of the individual. In addition, there may be adverse effects on animals, vegetation and on property, contribution to low or poor visibility, damage to clothing and foodstuffs, soiling of clothing, et cetera. These effects may be calculated in terms of monetary loss as differentiated from the loss of human life where the value cannot be expressed.

From the public health viewpoint, the adverse effect of polluted air on the individuals in the community is the main concern and depends on the degree of intensity of the air pollution present. According to Cooper and Stern[1] of the U. S. Public Health Service, "The intensity of air pollution may run the gamut from severe episodes causing death, acute exposures sufficient to cause annoyance but without provable health effects, and exposures for prolonged periods to low concentration of contaminants which may cause chronic effects still unrecognized." Several of the severe exposures for a relatively short duration have already been discussed. With the exception of the Poza Rica episode caused by the accidental release of hydrogen sulfide, the causative agent or agents for the disaster are not difinitely known. Inconclusive evidence points toward sulfur dioxide, certain fluorine compounds, other particulate matter and oxides of nitrogen as the most likely materials to have caused the deaths and illnesses. It is highly probable that it was not one agent alone but the combined action of two or more contaminants acting in a synergistic manner. It has been pointed out that most of the deaths were among persons of advanced age already weakened by other illnesses. However, persons of all ages and states of health became ill and required hos-

pitalization or medical treatment in all of these episodes and in the Poza Rica incident, the deaths occurred in the same pattern.

These severe episodes have proved that the effect of air contamination upon human life can be fatal. What about a less severe attack—either with an equal concentration of contaminants for a shorter duration or a lower concentration for extended periods? This is the area in the field of air pollution effects on human health that has not been solved in the few years of study of the problem. It may take years of work on carefully designed projects to show any definite trends. Needless to say, these studies must be quite lengthy and costly, so the number of completed studies will be small.

A good example of mild exposures to air pollution contaminants over an extended period of time is the smog problem of the West Coast principally in the Los Angeles area. Since early in the Second World War, certain health nuisance effects have been noted by the people and the problem, although possibly lessening, has not been controlled. In the Los Angeles area, the rapid growth in population and industrial development over the past several decades has increased the air pollution load contributed from many different sources. In addition, the meteorologic features of the entire West Coast, and especially the lower portion, help in making the problem difficult. The Los Angeles area, ringed by fairly high mountain ranges, has a twice daily shift in winds, usually from the mountains toward the ocean in the morning hours and the exact reverse during the afternoon and evening. In this manner, the same parcel of air receives the contamination from the many sources in the area. A persistent temperature inversion prevents dissipation of the pollutants over the mountains. The effects on vegetation, visibility and property have resulted in millions of dollars in damage. On health, the effects have not been clearly defined. Mills,[2] by means of statistical study, showed a higher-than-normal mortality during some extreme smog periods but other studies of the same data disputed his finding. Those who have experienced this smog, which is frequently characterized by the presence of a lacrimatory agent, will readily acknowledge the nuisance value. It is now generally agreed that the probable cause of the Los Angeles smog is a reaction between hydrocarbons, oxides of nitrogen and ozone or total oxidant in the air. Several studies now in progress may answer the question as to whether periodic exposures to this type of air pollution will cause permanent damage to health.

Under the stimulus of Public Law 159, 84th Congress, in which funds were appropriated for research and technical assistance relating to air pollution, a number of studies are being conducted throughout the country on the effects of air pollutants on human health. These studies may be divided into three general types: (1) community and other epidemiologic studies, (2) statistical analyses of morbidity and mortality and their possible relationship to air pollution indices, and (3) toxicologic effects of air pollutants.

The statistical studies on correlation between morbidity and mortality and certain air pollution indices will furnish information for additional investigations. Toxicologic experiments on exposures of various animals to varying concentrations of air pollutants will develop information on potential hazards on human health. Aided by the data from these investigations, the function of community and other epidemiologic studies will be to identify causative agents and to establish scientific standards for allowable concentrations of such agents in the air. The standards may vary from community to community and from one section of the country to another depending on various factors.

An investigation recently started in metropolitan Nashville, Tennessee, sponsored in part by the Public Health Service, is a good example of a community study on total health effects. This project combines a medical investigation of the inhabitants of the area and an engineering and physical science study of the environment to which the people are continuously subjected. The latter study will provide thorough and comprehensive data on the concentration of certain contaminants in subdivided areas of the community. These data will be correlated with medical findings obtained in a series of studies—including surveys of morbidity, mortality, frequency of occurrence of cardiorespiratory diseases and incidence of anthracosis. The findings of this carefully planned project should aid materially in the establishment of permissible standards for contaminants of the environment.

There are other effects on the health of the people of our communities besides those derived from inhaling contaminants or from direct irritation of the eyes. With the formation of numerous smogs in a community, the amount of sunlight reaching

the earth's surface can be reduced materially. The lessening of sunlight, besides having an effect on growth of vegetation, may also have adverse effects on humans due to a decrease in solar ultraviolet radiation. This probably can be counteracted by consuming artificially irradiated milk or by other dietary supplements containing vitamin D. There is still the possible effect of a dark gloomy day on the mental health of the people in the community. Smoke, dust, dirt, odors, soiling of clothes are a constant problem of people living in certain communities. Visualize a housewife who has hung her wash on the line, only to discover a few minutes later that oily soot has soiled all her clean clothes. Don't you think that this situation, often repeated, would have a direct relationship to mental health?

Responsibility of the Community

In many of the communities, the question at the present time is this: Does our community now have an air pollution problem? or How does one know when the contaminated atmosphere of a community constitutes a problem? An air pollution control official of one of the larger cities made this statement:[3] "In order to define the problem in more specific terms, let us acknowledge that every community has polluted air in some degree but that a community enters upon a realization that an air pollution problem exists: (1) when there is a serious effect on the general health of the community reaching the proportions of a disaster, or (2) when the nuisance from dirt, soil, fumes, and odor is beyond the tolerance of individual citizens and they become dissatisfied and express a public desire for cleaner air." The second criterion is a subjective approach and should be backed by other means of analysis. Air contamination might get progressively worse in a community with the people accepting the condition as a sign of prosperity and not raising the necessary objections to start remedial action.

Our communities should not wait for a serious episode or some other obvious indication that the air pollution threshold has been reached or exceeded. Before the problem gets out of hand, as it may in many communities in the future, certain steps may be taken to control the situation. A careful examination should be made of the complaints, potential sources and obvious effects on vegetation and property and possibly changes in the types of weather. If the local health group does not have the qualified personnel to make such a study, the State Health Department should be consulted. If necessary, the State Health Department may call upon Federal experts in this field. Along this same line, do not forget the well qualified staffs of our colleges and universities.

In setting up an air pollution program for a community, consideration should be given to the fact that the emissions from air pollution sources do not respect city boundaries. An industrial plant outside the city limits may contribute heavily to the air pollution problem in that city and the reverse is also true. Communities in certain sections of the country have formed air pollution control districts consisting of one or more counties so that all potential sources come under one jurisdiction. This should yield much better results than to have separate programs in all of the cities and towns in a metropolitan area.

There are many other aspects of a successful air pollution control program which should be mentioned. An adequate budget for salaries of trained personnel and necessary field and laboratory equipment should be established. Control legislation to fit the paticular air pollution problem of the community must be enacted. Future community planning or zoning should take into account certain factors of air pollution control—especially prevailing wind direction, wind speeds, topography and even orientation of industrial plant buildings. An educational program for both industry and the people in a commuity can be a very important part of the control program.

Conclusion

It should be stressed that the air pollution problem is not confined to large cities or communities. Some of the well known disasters in which many people died and other serious effects occurred took place in communities much below 30,000 in population. Local health departments should accept the challenge of this public health problem and plan in the future to provide a cleaner, safer air for our communities.

Radiation

An Environmental Health Factor

Presented in symposium at the Minnesota Public Health Conference, Saint Paul, Minnesota, September 19, 1958.

THIS discussion of radiation hazard will be limited to natural radiation, fallout from nuclear weapons tests, and potential wastes from the peaceful application of atomic energy. Sources of ionizing radiation other than natural radiation are becoming increasingly important pollutants of the air, water, feed and food.

Background or natural radiation contributes to an external and an internal radiation exposure. External exposure is due to cosmic rays and gamma rays from potassium, uranium, thorium and daughter products in the ground. Internal exposure results from the ingestion of such radioactive elements as radium and potassium-40 in water or food or from the inhalation of radon and thoron gases and their daughter products released to the atmosphere following decay of parent products. Urban air pollution aerosols, on which radon daughter and thoron daughter products are absorbed, might cause increased retention and thus greater lung exposure.

It is the purpose of this presentation to review our understanding of the maximum permissible concentration of radionuclides and apply that concept to available data on the abundance and distribution of radioactivity in the environment.

Maximum Permissible Concentrations

All ionizing radiation, however small, is harmful and should be avoided.[1] The effects from exposure vary with the amount of radiation, ranging from genetic and somatic effects at low levels to the complete destruction of vital body cells at high levels. The U. S. Atomic Energy Commission and scientists the world over are making exhaustive studies on the physical, chemical, and biologic aspects of radionuclides, and national[2] and international[3] committees appraise the information as it affects the recommended maximum permissible concentration (MPC). The National Committee on Radiation Protection[2] adopted 300 millirads per week as the maximum permissible dose for occupational workers (40-hour week).

From this basic dose value, the MPC of radionuclides in air, and water (or food) were derived and reported in NBS Handbook No. 52,[2] on the assumption that each radionuclide is the sole contributor of radiation exposure other than back-

Dr. Setter is Chief of Radiological Investigations, Division of Radiological Health, Robert A. Taft Sanitary Engineering Center, U. S. Public Health Service.

ground. The nature of the exposure of the general public would indicate that these levels should be reduced to allow for the following:

1. Multiple sources of exposure (ingestion, inhalation, and external exposure) including medical use of radiation.

2. Composition of the general population—presence of more sensitive persons such as children and expectant mothers.

3. The increased genetic effects for total population.

The degree of reduction which should be applied for each of these variables is unknown but an overall reduction factor of 100 will be selected as a basis for this discussion. Therefore, "significant levels" (SL) of radionuclides in air and in water shall be defined as one one-hundredth of the maximum permissible concentrations, as given in Handbook No. 52.

TABLE I. SIGNIFICANT LEVELS OF RADIONUCLIDES
(1% of Maximum Permissible Concentration)

Source	Radionuclide*	Critical Tissue	Significant Levels	
			In Air $\mu\mu c/M^3$	In Water $\mu\mu c/l$
Fission products	Strontium-90	Bone	2	8
	Iodine-131	Thyroid	30	300
	Cerium-144	Bone	70	400,000
	Strontium-89	Bone	200	700
	Ruthenium-106	Kidney	300	1,000,000
	Yttrium-91	Bone	400	2,000,000
	Barium-140	Bone	600	20,000
	Promethium-147	Bone	2,000	10,000,000
	Cesium-137	Muscle	2,000	15,000
	Niobium-95	Bone	4,000	4,000
	Ruthenium-103	Kidney	7,000	100,000
	Xenon-133	Body	40,000	40,000
Natural activity	Radon-222	Body	100	20
	Radium-226	Bone	0.8	0.4

*Includes radiation effect of daughters.

The SL values for more important or abundant radionuclides formed by the instantaneous slow neutron fission of U^{235} are listed in Table I.

The significant levels (SL) for natural radioactivity of radium and radon are noted to be relatively low. Of the mixed fission products, strontium-90, iodine-131, cerium-144 and strontium-89, in that order, have the lowest SL in air, whereas strontium-90, iodine-131, strontium-89 and niobium have the lowest SL in water.

One week after fission, most of the radioactivity

resides in thirty radionuclides. The total activity decreases in such a manner that the average half-life is roughly equal to the time since formation. More specifically, the mixed fission products decay

TABLE II. SIGNIFICANT LEVELS OF MIXED FISSION PRODUCTS AS A FUNCTION OF TIME

Age of Fission Products Days	Significant Levels*	
	In Air $\mu\mu c/M^3$	In Water $\mu\mu c/l$
3.12	800	7700
6.7	450	4300
14.4	360	3300
21.1	370	3200
30.9	410	4700
66.4	390	2500
143	220	1300
438	160	260

*Calculated values using abundance data of Bolles and Ballou (4), and 1/100 of MPC values of Handbook 52 (2).

with a negative exponential factor of 1.28 until three days old, 1.0 between the ages three and thirty days, 1.2 between the ages thirty and 100 days and 1.35 between the ages 100 and 1000 days. A factor of 1.2 provides a rough estimate of decay between the ages one day and one year. Some long-lived radionuclides such as strontium are formed in small amounts soon after fission, but account for a very small per cent of the total activity until the more abundant short-lived radionuclides have decayed through many half-lives. Some parent radionuclides have long-lived daughters which grow in amount as the parent decays, whereas other radionuclides have short-lived daughters which remain substantially as abundant as their parent.

Based on the radionuclide abundance data of Bolles and Ballou,[4] and using the Handbook No. 52 formula for calculating the MPC of mixtures of isotopes, the SL values for mixed fission products of different ages were calculated.

Table II shows that the SL of mixed fission products in air varies from 800 $\mu\mu c/M^3$ for three-day-old to 160 $\mu\mu c/M^3$ for 1.2-year-old mixtures, and that the SL in water varies from 7,700 $\mu\mu c/l$ for three-day-old to 260 $\mu\mu c/l$ for 1.2-year-old fission products. Since the preponderant air particulate and fallout activity is rarely older than three months, the significant levels are in order of 300 $\mu\mu c/M^3$ for air and 2000 $\mu\mu c/l$ for rain water.

The potential removal of cerium, zirconium, and yttrium from rain water by coprecipitation on silt in streams or reservoirs would inrease the relative abundance of the more radiohazardous elements such as iodine, barium and strontium. As a consequence, the SL for the residual radionuclide mixture would decrease.

The fission of fuels other than U^{235} may also alter the relative importance of fission products, at least temporarily. The presence of bomb construction material or the proximity of bomb detonation to soil or water may induce activity of considerable abundance. Induced activity may be either short-lived or long-lived and of variable radiotoxicity. Accordingly, caution should be exercised in interpreting levels of radioactivity on mixtures whose composition has not been fully established.

Air Particulate Activity

The results of a National Air Sampling Network[5] show that the average beta activity of atmospheric particulates in the U. S., exclusive of the area within 400 to 500 miles of the Nevada test site, was 1.0, 1.75, 2.05 and 5.4 $\mu\mu c/M^3$ in 1954, 1955, 1956 and 1957, respectively.

During Pacific and foreign tests in 1954 and 1956, maximum values of less than 22 $\mu\mu c/M^3$ were observed. Generally, the levels of activity were quite uniform over large areas of the U. S., with the frequency of maximum values appearing at the Rocky Mountain, Western, Southern, Central and Eastern areas in that order. The activity decay rates in 1954 and 1956 were characteristic of mixed fission products more than two weeks and less than three months old.

During the U. S. tests at Nevada in 1955 and 1957, activity levels fluctuated greatly as each test cloud moved by a different route generally southeastward with horizontal dispersion into the South-Central states and thence in an east-northeasterly direction up the Ohio and Tennessee Valleys to the North Atlantic states. With some exceptions in 1957, the Canadian border states, the Pacific, the Atlantic, and to a lesser degree, the Gulf Coastal areas showed lower levels of atmospheric particulate activity than elsewhere. Values of 2000 to 5500 $\mu\mu c/M^3$ were observed several hundred miles from the test site on only three occasions during the five years of testing. Elsewhere, maximum values of 100 to 350 $\mu\mu c/M^3$ were observed in the Central, Southern and Western areas and 75 $\mu\mu c/M^3$ in the Eastern area. In these samples of maximum activity, the decay rate was high and characteristic of one-day-old to five-day-old fission product. One-day-old fission product, for example, decays to 10 and 1 per cent of its original activity in seven and forty-two days, respectively.

The level of long-lived alpha activity in samples of the National Air Sampling Network has been low—usually below 10 $\mu\mu c/1000M^3$, or hardly detectable by the testing procedure. On the other hand, the short-lived natural activity of radon and thoron daughters is readily detected by alpha counting samples of one-cubic meter collected over an hour's time. Depending on time of collection, 1 to 5 per cent of the alpha activity has a half-life of 10.6 hours and is identified by decay as the daughters of thoron, whereas the remainder has a half-life of thirty-one to thirty-three minutes and is identified as the daughters of radon. A number of tests have indicated that natural activity at Cincinnati, Ohio, and at Hagerstown, Maryland, fluctuate through a diurnal cycle reaching peaks during the early morning and low levels in the early afternoon. However, peak levels persist during prolonged inversion conditions and minimum levels appear associated with high soil moisture, precipitation (washout from rain or snow), freezing temperatures, and high winds (dispersion). The morning values of radon fluctuate from 80 to 800 $\mu\mu c/M^3$ with a maximum observed value of 2000 $\mu\mu c/M^3$ at Cincinnati. Afternoon or low values are rarely less than 60 $\mu\mu c/M^3$. From limited data available, the daily average concentration is estimated to be 80 $\mu\mu c/M^3$ or more.

Fallout

Cincinnati rain collectors consisting of polyethylene buckets, 7 inches in diameter, and a 2 M^2 tray are emptied (with rinsing) before, during, and after rains, and the samples tested for beta activity, decay and isotopic composition. Numerous tests indicate that 85 per cent or more of the fallout occurs as rainout or snowout.[6] Usually the level of activity does not change significantly during a storm of a few hours' duration. Dustout has been minor even when the air particulate samples have indicated high atmospheric contamination. Occasionally, however, significant dustout has been obtained several days after high rainout. This is attributed to rain fallout which has become airborne by local wind or vehicular disturbances. In a few instances, dustout decay has been characteristic of a previous rain, whereas the preponderance of air particulate activity at the time of dust collection had a decay rate characteristic of a more recent nuclear test.

TABLE III. CINCINNATI FALLOUT OF ONE-YEAR-OLD ACTIVITY

Year	Month	Rain,* (Inches)	Beta Activity (One-Year-Old**)		
			Total $m\mu c/M^2$	Dissolved $\mu\mu c/l$	Total $\mu\mu c/l$
1957	Jan.	3.0	9.0	37	150
	Feb.	3.2	10.0	55	125
	Mar.	1.2	10.0	85	310
	Apr.	6.4	22.0	35	142
	May	6.0	12.5	50	80

1957 Average		—	—	68	168
1956		42.0	150.4		141
1955		45.0	63.2		55
1954		36.0	37.5		41
1953		22.0	31.3		56
1953-1957 Total		194.7	494.5		—
1953-1957 Average		—	—		100

*Includes snow.
**Sr-90 activity of unclassified mixed fission product estimated at 2.3 per cent (4).

In 1957, the total fallout from 50 inches of rain (including some snow and dust) was 14.18 $\mu c/M^2$ or an average concentration of 1230 $\mu\mu c/l$. However, 12.5 $\mu c/M^2$ was only two to five days old and 1.68 $\mu c/M^2$ was ten days to three months old. Since long-lived activity presents the greater potential hazard, the Cincinnati fallout results have been extrapolated from decay data to age one year as shown in Table III.

The months of greatest fallout were April to September. These five months accounted for three-fourths of the annual fallout. This period of high fallout corresponds to the normal plant growing season!

Cistern Water Radioactivity

The water of six cisterns located within 15 miles of the Cincinnati rain collector were tested periodically in 1957—most frequently during the months of high fallout. The monthly average activity varied from 122 to 2530 $\mu\mu c/l$ at the time of collection. The annual average activity was 629 $\mu\mu c/l$. The dissolved activity ranged from 11 to 93 per cent of the total activity, with the lowest percentages of dissolved activity occurring in water collected soon after the rainout of relatively young bomb debris. The cistern samples were recounted periodically to establish the decay rate and extrapolate the activity concentration of one-year-old bomb debris. The monthly average of one-year-old activity of cistern water ranged from 10 to 129 with an annual average of 73 $\mu\mu c/l$, as compared to 168 $\mu\mu c/l$ in rain. From this it appears that over 50 per cent of the rainout is removed from the water in cisterns by sedimentation.

Stream Water Radioactivity

The State of Ohio Department of Health tests the radioactivity of grab samples collected each month from the principal streams of the State. Through the courtesy of F. M. Waring, Chief, Division of Sanitary Engineering, of that Department, the results were made available for correlation with Cincinnati rainout. The 1957 results of five stations on the Big Miami River from Venice upstream, including a station on Mad River above Dayton, a station on the Little Miami River at Newtown, and four stations on the Scioto River below Columbus were used for this purpose. Some of the stations were nearly 100 miles from Cincinnati so that the fallout at remote stations may have differed from that at Cincinnati.

The monthly average total activity from the ten stations ranged from 26 (in October) to 190 (in July), with an annual average of 70 $\mu\mu c/l$. From 35 to 70 per cent, with an average of 50 per cent, of the total activity was associated with suspended matter. When correlated with Cincinnati rainout (corrected for decay to the end of the month), only 0.6 to 25.7 per cent, with an average of 1.8 per cent, of the rainout was found in stream water indicating that natural agents, such as soil and vegetation, and decay were responsible for reducing the level of activity reaching the stream in the form of run-off or ground water. Although the high removal (98.2 per cent) is favorable to high quality drinking water, the long-lived radioactivity removed by vegetation and soil is unfavorable since the contamination may be incorporated in human and animal food by adsorption or metabolism.

Coagulation experiments performed on rain, cistern, and surface stream waters show that all of the suspended and a small part of the dissolved activity are removed by alum-lime treatment and filtration.[7] Treatment of these Ohio stream waters would yield an effluent containing an annual average of about 35 $\mu\mu c/l$ of residual beta activity. A single test of treated effluent water showed that of the one-year-old activity, the strontium-90 concentration was 5 per cent instead of 2.3 per cent expected in mixed fission product.[4] It may be predicted that the relative abundance of other (more soluble) radionuclides, such as I^{131}, Ba^{140} and Sr^{89}, would be greater in treated effluents than in mixed fission products.

Discussion

Comparing the average levels of activity in airborne particulate matter 5.4 $\mu\mu c/M^3$ for 1957 or 2.55 $\mu\mu c/M^3$ for 1954-1958 in the U. S., with the significant mixed fission product level of 300 $\mu\mu c/M^3$ for three-month-old material, it is apparent that the inhalation hazard is of minor public health significance. On the other hand, the average natural radon level at Cincinnati of 80 $\mu\mu c/M^3$, as compared to an SL of 100 $\mu\mu c/M^3$ (Table I), appears to have public health significance even though radon is a part of the natural radiation background.

It is also interesting to compare the 10 $\mu\mu c/l$ occupational MPC for radon in air with the concentrations in uranium mining atmospheres which Holaday and his associates[8] reported—maximum, median, and minimum values for seventy-nine mines were 59,000, 4100 and 70 $\mu\mu c/l$, respectively. Perhaps there are many areas of human habitation where the levels of natural radioactivity (radon and thoron) in air should be of public health concern.

In drinking water, the SL for one-year-old fission product was estimated to be 300 $\mu\mu c/l$. This level in rainout was exceeded only during one month in the last five years, July 1957. The 1957 average activity of rainout was 56 per cent, and the five-year average was 37 per cent of the SL. The trend line for rainout is increasing every year and is approaching what may be considered a

significant level. However, natural purification of cistern and surface waters lowers the water hazard since (a) half of the rainout is removed by sedimentation in cisterns, (b) only 2 to 3 per cent of the rainout is found in stream water, and (c) half of the stream water activity may be removed by conventional water treatment using alum-lime coagulation and filtration.

Should treatment of water for the removal of rainout be necessary, filtration and ion-exchange appear promising for waters low in calcium and magnesium. Filtration with alum coagulation would be effective in removing the suspended activity, and cation exchangers have high capacities for removing dissolved fission products in water of low hardness. Lime soda-ash treatment to precipitate fission products together with calcium and magnesium appears more promising for removing radioactivity from hard waters.[9]

The geological composition of water-bearing strata with respect to uranium and thorium should be reviewed, since well waters may contain significant quantities of radium or mesothorium and their daughter products. A knowledge of the geological formations and representative testing of well waters for radon daughters and radium should provide information for an assessment of their public health significance and of any need for removing excess amounts of natural activity.

Contributions of radiation to air, water, and the rest of the environment from nuclear reactor operations, the peaceful application of radionuclides, and chemical processing of spent nuclear fuel require special consideration, but these are areas where the hazard can be minimized by judicious site selection, determined by monitoring environmental samples, and controlled by providing adequate treatment of wastes.

Off-site monitoring stations should collect samples, measure radioactivity, and discriminate local sources of radiation from bomb debris and background. Bomb debris activity in airborne particulates is an indicator of high potential fallout during inclement weather, but rain collectors are more reliable for determining fallout and knowing when and where environmental samples such as water, vegetation, animal matter, and soil samples should be collected and assayed.

Summary

Significant levels of unclassified mixed fission product in air and water from the slow neutron fission of U^{235} have been calculated. The rate of decay of mixed fission products is utilized to characterize air particulate and fallout activity.

Airborne particulate radioactivity in the United States during the last four years represents a fractional part of what may be termed a significant level of contamination.

Fallout (rainout, snowout, and dustout) during the last five years represented contamination equal to 30 to 40 per cent of the significance level, but natural purification in cisterns and in surface waters substantially reduced the contamination.

Natural radioactivity due to radium and mesothorium and their daughters may present potential radiation hazards in air and water, and warrant more extensive investigation.

More extensive fallout studies are needed to determine distribution and the relation of fallout to the contamination of food and feed.

Radiation and Human Genetics

Presented in symposium at the Minnesota Public Health Conference, Saint Paul, Minnesota, September 19, 1958.

SOON after the discovery of radium and x-rays, physicians and others got radiation sickness and some died. As these deaths occurred, it became obvious that large doses of radiations to the whole body caused death, and that shielding and proper safeguards against death to the operators were necessary. Consequently, the grossest hazards were quickly remedied and not much further attention was paid to the dangers of irradiation for many years.

It is rather odd that one must obtain a prescription from a physician to purchase all sorts of relatively innocuous materials such as histamine diphosphate or banthene, while anyone can buy and operate a death-dealing x-ray machine if by chance he should have the money and the inclination to do so. Fortunately, most people who buy x-ray machines know how to take proper precautions and it is hoped that before long the State of Minnesota Board of Health will be in a position to require registrations for all x-ray machines and have safety control over them.

As a result of the bombing of Nagasaki and Hiroshima, it seems clear that a dose of 500 r. spread over the whole body will cause the death of half of the people so exposed and within a few years time after the exposure. All of those receiving this diffused whole body dose will be very ill with radiation sickness (rise of temperature, falling out of the hair, vomiting, et cetera. But if the rest of the body is shielded, a dose of 3,500 r. (or more) can be directed to a particular spot, such as the cervix, in order to destroy the cancer cells at that site. The chromosomes in the cancer cells are broken to bits by this large dose, thus preventing further growth and division of the cancer cells and also, of course, of normal cells which happen to be in the path of the x-rays.

The radiation from the bombing of Hiroshima and Nagasaki was responsible for the production of abnormalities in some fetuses in gestation at that time. The most obvious damage to the embryos was to their front ends and resulted in microcephaly; that is, much arrested development of the brain with resulting idiocy.

Everyone must agree that large doses of radiation received from accidents or from bomb explosions could only be disadvantageous and perhaps lethal. The area which is less well understood concerns the effects of small doses of radiations on man.

There is *not* agreement as to whether a small dose of radiation can trigger off leukemia or bone cancer or decrease longevity. Possibly a threshold dose, that is, a minimum amount, is necessary in order for these damaging effects to appear. It *is* known that chronic radiation of only 1 r. per week results in the loss of white blood cells.

It is very clear, however, and there *is* general agreement, that any amount of radiation, no matter how small the dose, increases the *rate* of genetic mutation (that is, permanent change) in the population. It is my purpose today to describe something of the nature of what is now a vast subject in itself, which may be called "Radiation Genetics."

In the late 1800's, August Weismann went to elaborate lengths to show that mutilations of the body such as cutting off the tails of mice did not affect the germ plasm or heredity of the individual.

SHELDON C. REED, Ph.D.
Minneapolis, Minnesota

From the Dight Institute for Human Genetics, University of Minnesota.

The idea grew that the gonads were perfectly insulated from the environment and that man and the other forms of life were unchangeable. In the twentieth century, biologists began to suspect that Weismann's theory, which considered the germ plasm to be inviolate, was incorrect. It was obvious that sports or mutations arose all the time, at a very low rate to be sure, and that something must be causing them. The technical difficulties of proving that mutations did occur were very large, but by 1927 proof was in hand that radiations were one agent which could produce mutations. The beautiful experiments which showed this were designed and executed by Professor H. J. Muller who later received a Nobel Prize as a reward for his success.

Muller proved, in the laboratory animal, *Drosophila melanogaster,* that there was a precise linear relationship between the roentgens of radiation put into the animal and the number of mutations shown in its offspring. The larger the dosage, the more mutations produced in the offspring. Sturtevant and Beadle have produced an estimate that in *Drosophila,* the laboratory fruit fly, every increment of 350 r. adds 1 per cent to the number of recovered mutations of the x-chromosome. This would be tripled at least if the other chromosomes were included. Mice have been found to be fifteen times as sensitive to radiations as *Drosophila* and perhaps man is even more sensitive than mice.

Bender[1] x-rayed tissue cultures of human cells with low doses and found that only 3.3 r. were required to double the number of chromosome breaks or mutations found in the control tissue culture cells. If this is true, that it only takes 3.3 r. to double the breakage in tissue culture cells, it means that the 10 r. recommended by the National Research Council as the maximum permissible dose which a person should have during his lifetime, may be too high. Members of the National Research Council did *not* say that 10 r. is safe. Indeed, this amount is certainly harmful, but it was their thinking that the resulting damage was all that society would accept. Society must accept some damage; it is only a question of how much it will pay for the advantages of radiation.

The reasoning of the expert committee of the National Research Council is based on the following data. It is estimated that 4 to 5 per cent of all live births in the United States have gross defects such as mental deficiency, congenital malformations, defects in vision and hearing. Of these about half appear to be of simple genetic origin. They are due to present or past mutations just like those produced by radiations. Consequently, of the next generation of 100,000,000 births in the United States, something like 2,000,000 of the generation will experience genetic defects of the sorts listed just now. According to the best data we have, the addition of 10 r. of man-made radiation to the natural causes of mutations already present, would add some 50,000 new instances of inherited defects to the next generation, and, if this increased dosage continued indefinitely, there would ultimately be about 500,000 additional defective children per generation. Thus, the 2,000,000 gross defects of genetic origin now observed each gen-

eration, would have risen to 2,500,000 in the distant future (20 per cent rise).

This is a frightening figure but it is certainly a reasonable one and is too low if Bender's observations on tissue culture cells are completely relevant. Even if the radiation to which the United States population is exposed is raised by only 1 r. per person, an additional load of 5,000 new defects would probably appear in the next generation.

This grim picture should give us an increased respect for radiation hazards which are easy to disregard since they cannot be seen, heard, smelled, tasted or felt.

The 2,000,000 children now born each generation with gross heritable defects result largely from mutations which occurred in past generations. In such cases where the child dies or fails later to reproduce, his mutation dies with him. Each generation the mutations that become extinct are replaced by different new mutations which result from natural or man-made causes. Some of these mutagens are cosmic rays, many chemicals such as formaldehyde, medical irradiations and to a slight extent, bomb-test fallout. It is thought that each person in the United States receives during his lifetime the *equivalent*, from all sources, of about 50 r. Of this 50 r., about 4.5 r. comes from cosmic rays at our elevation (in Denver, there would be about one more roentgen due to the higher altitude), 3 to 4 r. from medical irradiations and 0.2 r. from fallout. Most of the background causes are of unknown origin.

In medical use, fluoroscopy is much more dangerous than taking films because exposure is longer and probably scattering is greater. Five seconds of fluoroscopy is equivalent to 500 pictures. Fortunately, many of those getting large doses of radiations are past the reproductive age so that mutations produced in them will not result in deaths or defects in future generations.

However, this is an appropriate place to mention the occasional practice, now fortunately on the decline, of applying 200-300 r. units to the surface of the body overlying the ovaries in the treatment of sterility. This is extremely dangerous because the dose is so large that it is hard to imagine how new mutations can be avoided. From the point of view of the next generation, it would be better to leave the woman sterile rather than ensure that she will pass on disastrous mutations to whatever offspring might be produced as a result of the treatment. This is, of course, highly exceptional.

Usual doses of x-irradiation are:

Chest 14 x 17 in. film	0.1 r.
Chest photofluoroscopic x-ray	1.0 r.
Cardiac fluoroscopy and catheterization	10-140 r.
Gastrointestinal series—6 films	10-20 r. per minute
Gastrointestinal fluoroscopy	(5 seconds usual)
Full-mouth dental films	5.0 r.

Fortunately, not much of this gets to the gonads. In order to cause mutations, it must get to the gonads if the next generation is to be affected. Mutations in other parts of the body called somatic mutations, are relatively harmless, and die with the person affected.

You may ask, "Why is it that if just one little quantum of x-ray energy hits a chromosome in one sperm and this sperm happens to fertilize an egg, that the resulting child may die, be an achondroplastic dwarf or be damaged in some way?" The answer is that the chromosome that was hit by the x-ray will be in every single cell in the whole body of the child and thus will create its effect in every cell. Furthermore, the dwarf, if he has any children, will pass on the mutated chromosome to half of them. Thus, the damage is passed on for more than one generation, though eventually the mutant chromosome will be eliminated from the population.

Why are mutations always thought of as being harmful? If you throw a monkey wrench into a smoothly running motor there is a very large chance that you will damage it and only a small one that you will make it run better.

Finally, admitting the dangers of careless use of radiations and the resulting damage, where does this fit into the whole picture which includes the tremendous advantages of the harnessing of irradiations, that is, atoms for peace?

No one would suggest that x-ray machines be abolished. Radiant energy is here to stay. The only sensible attitude is that of the balance sheet of business. We must increase the profits by cutting the costs. Rigid safety precautions are the only answer and every physician should always have this foremost in his mental picture of his x-ray equipment.

The Cardiac Patient

Employment in Industry

● *The role of the personal physician, his industry, and union, are important not only in helping the cardiac patient recover from his acute illness but also in planning the patient's future employment and livelihood.*

ARTHUR C. KERKHOF, M.D.
Minneapolis, Minnesota

Inaugural Thesis read before the Minnesota Academy of Medicine, meeting of October 8, 1958.

THE employment of cardiac patients, particularly those with coronary disease is becoming an increasingly important medical problem, in addition to having far-reaching social and economic implications for the individual, his family, and his community. The constantly increasing average age of our population, together with better diagnosis and improved care of the patient with coronary disease has steadily increased the number of such patients in the employable age group. Recent figures show that about three quarters of a million new cases of coronary thrombosis recover sufficiently to be able to go back into industry each year. This is an impressive figure, and therein lies the problem. We also know that about 75 per cent of men in the United States at the age of twenty-one have significant amounts of coronary arteriosclerosis, and this of course means that the problem of employment of the cardiac patient may be expected to increase rather than diminish. This figure also suggests that at least 80 to 85 per cent of men at age forty have some coronary disease. Routine electrocardiograms at age forty taken at the Twin Cities Arsenal show that approximately 7 per cent of those individuals have significant abnormalities. These statistics are of concern to members of industrial management. If industry interpreted these facts rigidly, one logical conclusion would be to eliminate from employment all men over the age of forty. This is so obviously irrational from the standpoint of either common sense or our national economy that other solutions to the problem must be explored.

What problems do we face in the employment of the cardiac patient, and how can they be solved?

The major problem is that of fear—fear on the part of the coronary patient that he will injure himself or precipitate another attack by working. This fear can be dispelled. There is evidence to show that at least 65 to 70 per cent of all post-coronary thrombosis patients go back to their former jobs no matter what those jobs were. Patients must be reassured concerning this matter and concrete examples should be cited.

One sound step towards dispelling these dangerous fallacies has been through the organization of "Coronary Clubs" throughout the country. They consist of individuals, both lay and professional, who have had myocardial infarctions and who are trained in the indoctrination of others in the proper attitude towards their disability. Properly directed and oriented, these club members can be most helpful in improving the mental attitude of persons newly stricken. Such a club is now being currently formed under the auspices of the Minnesota Heart Association and they will soon be able to assist in this problem.

Industry is also fearful. They know about the compensation losses. They are faced with the practical problem involved in employing an individual who must, at times, be limited in his efforts. They hesitate to invest a considerable training period in such an individual. Now that medical care and sick benefits have been added as a fringe benefit in many industries, it becomes obvious that management does not want to load its insurance program with individuals who might be poor risks in such a plan.

Labor also has its fears. One certainly is the fear that physical disabilities cause unemployment for the individual. Labor is jealous of its seniority system and the right to maintain a position despite a physical handicap. Yet some of its interpretations discriminate against the union member who could possibly do less active work providing adjustments of seniority rules could be satisfactorily worked out.

Labor is being faced more and more with a problem growing out of the spread of welfare plans. If disabled union members cannot go back

to work they are dependent upon the welfare plans supported wholly or in part by union contributions, and it is easy to see that long-term disabilities of a number of workers can be a constant drain upon those welfare funds.

Probably one of the major factors in employment of the individual with a cardiac ailment involves workmen's compensation. Originally these laws were enacted to protect the employee and his family if the employee suffered death or disability while on the job. These laws were designed to mitigate the appalling industrial accident and death toll; they were, for the most part, liberally drafted and liberally interpreted. They unquestionably favored the employee. As long as compensation laws concerned themselves with true accidents only, there was no great problem. However, in recent years, these laws have been progressively enlarged and their interpretations have also been widened. Heart disease, particularly coronary disease (a process of degeneration), has now been brought within the scope of this law. Some states rule that occurrence of a coronary thrombosis at work has a direct cause-and-effect relationship. Special groups, particularly firemen and policemen, have been provided for under the laws of some states. The laws in those states provide that any heart disease occurring in an individual belonging to such a specified group is automatically presumed to rise out of his employment and thus is an automatic matter of compensability. However, these laws do not specifically state anything concerning heart disease aside from their application to these special groups. It is a matter of interpretation of the law by workmen's compensation boards. The tendency of these boards and the legislatures has been to favor the employee's position, and in so-doing, benefits and coverage are being extended to more and more individuals for more and more disabilities. Naturally, employees with heart disease have fallen into this liberalized interpretation of the present workmen's compensation laws.

I am interested and concerned with the attitude and philosophy of the physician towards workmen's compensation problems. We are all familiar with the physician who always testifies on the side of the plaintiff and the physician who always testifies on the defendant's side. The actual facts in each case are usually perfectly clear and uncontested. Therefore, the widely differing opinions of several physicians facing the same admitted facts must depend on other factors besides the evidence. In other words, the philosophy, background and training of the individual physician causes him to interpret facts differently than his colleagues. One might speculate whether or not the physician who always appears for industry feels basically insecure and is bolstering himself by linking himself with a large corporation. One may also speculate if the physicians who always appear for the plaintiff have an inherent dislike of "big business" and feel that they must champion the cause of the oppressed. Whatever may be the reasons, the practical result is that testimony before an industrial commission or before a court becomes a contest. One physician looks at the case and decides that the evidence favors the plaintiff, and when he appears in court that physician sees no shade of gray. Things are either black or white; the same of course can be said for the physician who appears for the defendant.

Similarly there are differences between the private physician and the industrial physician. In my own case, I find I have what might be called a case of medical schizophrenia, for I find myself arguing on both sides of the question. As a physician in private practice I advise my patient with coronary thrombosis to go back to work. I have told him that he can return to his original job with no injury to himself or to his fellow workers, and that he will have no difficulty. Then I swing my chair around and as an industrial physician I see that same patient, and tell him that I cannot employ him in the industry where he originally worked; that because of his coronary thrombosis I cannot place him back in the work he formerly did because the industry wishes to protect itself. Obviously, if I am thrust into this awkward, perplexing, and somewhat frustrating experience as an individual, there is ample and justifiable reason to expect even wider and sharper differences to occur between several physicians who are wedded even more irrevocably to their points of view than I am.

In an attempt to crystallize the viewpoints of physicians on this problem, Ehrlich conducted a poll of internists and cardiologists and reported his findings.[1] He sent out a questionnaire to these hundreds of physicians and obtained their answers. The following are the conclusions:

1. Work does not produce heart disease (vote 94 per cent to 1.5 per cent).

2. Coronary arteriosclerosis or some form of

coronary disease must have pre-existed in an indivdual who suffers a coronary occlusion and myocardial infarction (vote 93.4 per cent to 6.3 per cent).

3. Performance of the same type of moderately heavy work without engaging in unusual exertion or strain has no injurious effect upon the heart. A myocardial infarction occurring during such work is not causally related to employment (vote 88.6 per cent to 7.1 per cent).

4. Subsequent attacks of myocardial infarction are not causally related to the first attack but to the underlying pathology of the coronary vessels of the heart (vote 82.8 per cent to 12.9 per cent).

5. Opinion on the effect of a strenuous physical exertion or emotional disturbance upon the heart was diveded (46.6 per cent considered that there was a causal relationship between strenuous work and ensuing myocardial infarction. 49.5 per cent did not believe so. Emotional factors were considered slightly more important than physical factors).

6. Opinion was divided on whether a person has a permanent partial disability after he has recovered from his myocardial infarction and returned to work asymptomatic. (45.8 per cent felt there was a disability and 47.9 per cent that there was not).

It is commonly stated by those individuals who are endeavoring to get the cardiac patient back into industry that the cost of compensation for the cardiac is minor. This is not the case. In 1949 in New York State, although the number of cases involving workmen's compensation in cardiacs was only .18 per cent of the total, the cost of those cases was 2.5 per cent. The cardiac cases averaged $9,400 each. This should dispell any thought that the cost of compensation in these cases is incidental and relatively unimportant.

There are other managerial problems beyond compensation. In most industry today a certain amount of training is needed to develop the employe to the point where he becomes a useful and productive worker. Industry is, of course, very careful in the selection of individuals for this type of training. Managers are probably not going to select a candidate for training who has a fairly decreased life expectancy or work potential. This has a marked tendency to eliminate the post-coronary patient from such a program. Industry also has another problem of not always being able to provide light work. Many industries have labor pools for example, out of which an individual can be taken to do practically any type of work. If the industry is large enough there may be sufficient light jobs to be used for this purpose; but in a smaller industry, where the employes must do various types of work, it is sometimes impossible for the industrialist to limit the activity of any given employe. Also, whatever light jobs occur are often kept for those who develop illness while in the employ of the company and these jobs are therefore given to them on return from their illness.

The unions, of course, have a very definite problem. In many cases the industry works with a so-called union hiring hall. Under this system the individual is assigned to jobs solely on a rotation basis and, therefore, whether or not he has heart disease plays no role in his right to take a job. This poses two problems. First, it is unfair to the employe himself. He might take a job beyond his physical capacity and this could aggravate his disability or even cause his death. The union in a sense takes a certain responsibility for this when it permits this individual to take the job. On the other hand, seniority is one of labor's corner stones and any changes, even though desirable from the medical standpoint, would necessarily have to be approached slowly and systematically. After all, the older an individual gets and the more seniority he has built up, the better chance he has for choosing the type of job he might like to do. Because of this, the easier, lighter jobs are given to those individuals high on the seniority list. It is unfair then, from a union's standpoint, to allow someone with a disability to circumvent the seniority list and take a lighter or easier job which others, through length of service, have a prior right to.

There are also problems in an industry where, for example, trade unions are used. Let us assume a man is a bricklayer. The only thing he can do, under his union rules, is to lay bricks. Possibly this is more than he can do because of his cardiac status and the man is unable, because of his training potential, age, or inclination, to adapt or prepare himself for something else. The union can do nothing for him if he cannot do the work of a bricklayer. In other industries where they have an industry-wide organization, it is possible to shift a man from one type of a job to another without violating union contracts.

The industrial physician giving pre-employment examinations has a problem. As a physician and

as a person he would like to see that all the individuals with coronary disease (who are able to do so) should be productively employed and continue to live a normal life with as near normal a life span as possible. On the other hand, he is charged with reducing the compensation losses in his industry. Knowing the facts as they exist today, he must, therefore, reject such individuals unless he can be absolutely sure that the work to which they will be assigned will not in any way contribute to disability or death for the employe.

It becomes imperative, therefore, that the industrial physician know the work requirement of the various positions within his industry so that he may adequately place those individuals he finds able to work.

Employment of the cardiac is without question a major industrial and medical problem. However, changes can be made to improve opportunities for this large group. The first step involves changes in the interpretation of the compensation law. Actually, we are dealing here with a degenerative disease, a disease which begins in early life and progresses with age. Because of this chronic degenerative process associated inevitably with aging, it would seem that this type of disease falls in a different category than a broken leg or an injured back. It would seem that we should have entirely different interpretations of this illness.

Attempts have been made to decrease the liability on the individual employer. In Minnesota we have a "second injury law" patterned after laws in other states. This law at the present time has several provisions. First, the employer must list with the industrial commission the physical or mental defects of his employes. Second, in the event of an accident involving an individual already listed as having a pre-existing disability the employer may apply for reimbursement for the increased cost incurred by reason of the original disability. Third, in no event shall the employer be liable for more than 104 weeks of compensation and the medical costs in such a case. Relief beyond this will be obtained from the second injury fund. This has been held out as a hope to industry in the case of cardiac patients but in my opinion it is not adequate. Actually, as we know from the opinion of physicians in the poll by Ehrlich, coronary thrombosis does not occur except in those individuals who have pre-existing artery disease. In other words, coronary thrombosis always is a second injury. It is never a first injury and, therefore, under those circumstances should always be listed under the second injury fund. Under our present law, however, the employer must list with the industrial commission the fact that the individual had a defect prior to the incident which is requiring compensation. If the employer wishes to do this correctly at the present time, he will very frankly state that all of his employes have coronary disease. At least he will be correct in 85 per cent of them. This of course is a farce and, therefore, the only solution is to amend this law so that all cardiac disease is listed as a second injury and never as a primary injury. Although this would relieve the employer somewhat, it still would not relieve him entirely because he still would be faced with 104 weeks plus the medical and hospital cost and this can easily amount to $8,000.00 or more in each case.

I believe there is another solution to this problem. It would seem to me that at no time is a coronary thrombosis entirely the result of anyone's employment. Neither is a coronary insufficiency resulting in death entirely due to the work of the moment. These individuals have pre-existing disease to a great extent and some incident comes along to change the course of events. It would seem that instead of things being either black or white, there are shades of gray involved. Even though a man develops a coronary insufficiency as a result of heavy work and dies, not all of this is due to the work of the moment. Much of this difficulty was related to the coronary disease and the marked narrowing of the coronary arteries which was pre-existing. In other words, it would seem more logical that we allocate 10, 20, 30, 40, or 50 per cent or even more of a man's death as a result of the effort at the time, and that the remaining percentage be judged as the result of the existing disease and not assessed totally to the job. We would then be in a much better position to judge this more equitably than we do at the present time.

The second thing we ought to do is avoid the contest type of medical testimony. As we have previously discussed, certain doctors are always on one side of the fence and certain others on the other. It would seem to be much wiser to have these cases judged by a panel of doctors as illustrated by the Utah plan. In this procedure, a panel of cardiologists is selected in a rotating fashion. They hear the evidence and render a decision. The compensation court so far has always accepted the panel's recommendations for

compensation, even though the board is not obligated in any way to be bound by the panel's decision. This avoids the contest type of testimony in court and gives a more responsible judgment of the case.

The establishment of a work classification unit would also appear to be a useful step. These units, and there are now about fifty throughout the country, are composed basically of a physician, a medical social worker, and a vocational counsellor. Other professional disciplines may be represented, too, but these three are the central personnel. A work classification unit does not diagnose, treat, or cure heart disease; it is an adjunct to the physician in his effort to see that the patient he treats is placed on a job that is no danger to the employe himself or to his colleagues. One of the amazing results of the work of these units is that the carefully kept records of two major centers revealed that over 2,000 clients were successfully placed in jobs and that not one single claim arising out of workmen's compensation occurred in this group.

A work classification unit is usually attached to a hospital, accepts patients only upon the referral of a physician, and is primarily oriented towards successfully placing the cardiac patient on a job he can handle. Complete reports are sent to the referring physician after the unit makes its recommendations. These recommendations are reached after a conference of the entire staff of the unit.

The Minnesota Heart Association is currently exploring the possibility of recommending that a demonstration unit of this kind be established to see what its practicality might be to this state.

The services of a work classification unit can be a useful assist in developing another important step in employment of the individual with a cardiac ailment, which is to develop better techniques of matching the man to the job he is best able to handle. The industrial physician should become better informed about the requirements of the positions in his industry so he may adequately fit the individual to the job. For example, the use of the word "light work" is often a misnomer, because the term has so many connotations. We need to explore this more explicitly. Union rules must be relaxed as far as seniority rights are concerned and I am sure leaders of the unions realize this. They realize they have a great stake in this problem, both from the point of trying to do the right thing by the individual, and from the financial point of their own welfare fund being greatly taxed if these individuals are not put back to work in an industry. Last of all, members of the medical profession must support such a program in order to make it work. It becomes necessary that we, as physicians, do our best to support some changes in the compensation law, that we assist in changes concerning medical testimony, that we assist in the work of a cardiac evaluation clinic and try to help industry and labor make a better selection and placement of these individuals.

Summary

1. Employment of the cardiac is a major problem today and is increasing in importance.

2. Much of the difficulty comes from fear on the part of the employe, the labor unions, and industry.

3. Excessively liberal interpretation of workmen's compensation laws is a major factor in employment of the cardiac patient.

4. The individual physician's role in workmen's compensation has a most important bearing on the "contest" philosophy presently obtained in these cases.

5. Questionnaires and documented findings show that the cardiac patient can take his place in industry.

6. Workmen's compensation cases involving cardiac patients comprise a proportionately large percentage of the total costs of workmen's compensation.

7. Both industry and labor have unique problems associated with employment of the cardiac and education is needed to change some of the current attitudes which hinder the cardiac from employment.

8. Changes in workmen's compensation laws seem to be desirable.

9. The possibility of establishing a work classification unit should be explored to determine its relevance to Minnesota's needs.

10. The physician's attitude, interest, and approach towards the individual involved in employment is still the primary determining factor and his increased knowledge and perception of the complex facets of the problem is the eventual key.

11. The Utah plan for establishing a panel of specialists reviewing cardiac cases appears to have merit and should be considered for use in Minnesota.

Common Ocular Trauma

Presented in part before the Interim Session of the American Medical Association, Minneapolis, Minnesota, December 3, 1958.

DAN M. GORDON, M.D.
New York, New York

From the New York Hospital, Cornell University Medical Center and the L. Margolyes League, New York, N. Y.

THE frequency with which a physician sees a specific type of ocular injury depends upon the nature of his practice. In an industrial neighborhood, foreign bodies and flash and hot oil burns would be most common. In a residential section, with a practice containing a high percentage of housewives, there would be many foreign bodies, corneal abrasions caused by brushes and infants' fingernails, and contusions due to open cabinet doors. In the event of a thermonuclear attack, radiation burns would present problems entirely different from those of everyday practice. The most common ocular injuries are those due to foreign bodies; direct blows causing abrasions, contusions, and lacerations; and thermal, chemical, or radiation burns.

The presence of anything in the eye which does not belong there constitutes an emergency. The foreign material must be removed by the handiest and safest method possible, usually by irrigation with water or some other bland fluid. Educational programs for children, workers, and housewives should stress the importance of immediate and copious irrigation with water, milk, or any other handy bland fluid if foreign material of any type enters the eye. After this generous eye bath, the patient should consult a physician. This immediate attention will often prevent blindness, especially in the case of chemical burns.

Workers who are exposed to the possibility of flying objects or to sources of flame should wear goggles. Hobbyists and "do-it-yourselfers" should be warned to use adequate protective devices. Incidentally, any patient who is struck in the eye with a flying particle while he is using a hammer or other metallic object should be instructed to bring in the tool so that it can be tested to determine whether it is magnetic or non-magnetic. It will also be helpful to locate the particle, because it can then be matched against the tool from which it has come to see if any missing portion may still be within the eye.

This paper is directed at non-ophthalmologists who may find it necessary to treat eye injuries, either because of the nature of their practice, or because the exigencies of the situation demand

medical care before a specialist can be summoned. Visual loss which is not obviously of a temporary nature demands consultation and treatment by an ophthalmologist. Before the non-specialist can treat ocular injuries, he must be prepared to approach the eye. This demands a minimum amount of equipment, including the following:

1. Some form of magnification, preferably a loupe, consisting of a combination of plus lenses and prisms, which can be worn either as a spectacle or in a head band.
2. A source of focal light, preferably a floor lamp, which throws a narrow, bright beam.
3. A treatment tray which should contain:
   (a) cotton balls
   (b) toothpick swabs
   (c) sterile fluid for irrigation, preferably in a squeeze bottle or an atomizer
   (d) topical anesthetic (tetracaine ½ per cent, ophthane, dorsocaine, et cetera, not cocaine)
   (e) a foreign body spud or hypodermic needles which can be used for the same purpose
   (f) fluorescein for staining the cornea
   (g) lid retractor
   (h) cycloplegic (homatropine ½ per cent, cyclopentolate ½ per cent)
   (i) eye pads
   (j) scotch tape

Although fluorescein comes in bottles of 1 to 2 per cent concentration, it is preferable to use fluorescein strips which come in sterile, individual packages. Since fluorescein is an excellent culture medium for pyocyaneous, the individual, sterile fluorescein strips eliminate the dangers of contamination inherent in using bottles of the solution. Actually, the less one relies upon stock bottles and eye droppers, the less the danger of contamination. If a lid retractor is not available, a heavy bent hairpin may serve the purpose. While cycloplegics should be available, they should rarely be used by the general practitioner and never after the removal of a simple foreign body. Many patients have been practically immobilized for a week or two by a dilated pupil following a trivial injury, owing to the unnecessary instillation of atropine.

It is mandatory to obtain a history of the accident, preferably from the patient himself, at the first visit, before "compensationitis" has had a chance to set in. It is amazing how often a simple foreign body in one eye will cause a need for reading glasses in an individual over forty. He has consciously or unconsciously neglected to do anything about his presbyopia before the accident, but is now convinced that it was caused by the foreign body. Also, long after the accident has occurred, the patient is frequently persuaded that the rich insurance companies are in a better position to take care of him than he is. If possible, vision with and without glasses should be determined and recorded before the eye is handled. Prognosis should not be discussed until the outcome is certain.

Every physician should learn how to evert the upper lid. It is important to have complete control of the patient. If the upper or lower lid is held firmly against the superior or inferior bony margin of the orbit, the patient will be unable to close his eyes when he squeezes. A head rest makes immobilization easier.

Whenever the cornea is involved, it should be stained with fluorescein so that any denuded areas may be more effectively highlighted. A drop of fluorescein is instilled into the anesthetized eye. After waiting a minute, the eye is irrigated with sterile saline or water. It is advisable to place a plastic apron of the type used in beauty parlors around the patient's neck. People resent having their clothes saturated with irrigating solution, especially if it is tinged with fluorescein. In addition to the major advantage listed above, the use of fluorescein strips will diminish this possibility. The patient is asked to look up, and the fluorescein strip is placed inside the lower lid of the anesthetized eye, which is then closed for a few moments. Irrigation is unnecessary. The eye is then examined with good focal illumination and magnification.

Following are some important points to remember in examining an eye, in addition to those that have been mentioned above.

1. Always evert the upper lid, since foreign bodies commonly tend to lodge on the shelf just inside the upper lid border.

2. If a foreign body cannot be found, hold the everted upper lid up while the patient looks down, and explore behind the lid with a moistened, tightly wound, cotton toothpick swab to ascertain if any foreign material is lodged in that blind area of the cul de sac.

3. Irregularity of the light reflexes on the cornea or loss of the normal mirror-like relucency of the cornea indicate corneal injury ar edema.

4. Blood in the anterior chamber, dilation or paralysis of the pupil not due to medication, distortion of the pupil, or subconjunctival hemorrhage after a history of a blow to the eye, indicate possible ocular damage. A shallow anterior chamber in comparison with the other eye points to a probable penetrating injury.

5. Normal vision is compatible with serious eye injuries.

6. Always examine with an ophthalmoscope, employing a high plus lens (plus 12 or plus 15), starting 6 or 8 inches from the patient's eye. Pick up the pupil and the red reflex, and slowly decrease the plus as you approach the pupil and examine the fundus. A corneal scar, foreign body, or lens opacity is seen as a dark spot in the red reflex. If there is vitreous hemorrhage or a large retinal detachment, the normal round, red reflex will be obscured or absent. A large vitreous hemorrhage will cause a black reflex. If fundus examination reveals any abnormality, consultation with an ophthalmologist should be secured. A retinal detachment is usually seen as a gray, elevated area over which the retinal vessels are black, rather than red.

7. An iris which trembles during movement of the eye indicates that the lens is either dislocated or absent.

8. A "black eye" or bleeding from the nose or ears following a head injury may mean cranial damage.

Management

For purposes of discussion, the eye will be divided into its geographic parts.

Orbit.—Injuries to the orbits may involve either soft tissue trauma with bleeding, lacerations of the brow, or fractures of the orbital rim. An important injury is the "Herb Score" type, in which the patient is struck in the region of the orbit with a hard or a soft ball. This will most commonly be seen in adults who play rarely and who have not learned that men should not play boys' games. The orbital rim will usually cushion a blow against the eye unless the offending object hits the relatively unprotected temporal side. A soft ball, with its larger circumference, is more apt to cause bony injury than a hard ball.

Emphysema and crepitation on palpation should lead one to suspect fracture of the orbital rim, and demand an x-ray examination. When a fracture of the floor of the orbit is not promptly corrected, the eye ball will drop and severe diplopia will result. Simple, uncomplicated lacerations of the orbital skin are sutured in routine fashion.

Sudden loss of vision accompanying an injury to the globe may mean fracture of the orbit resulting in laceration of the optic nerve or hemorrhage into the nerve sheath.

Blows to the lids most commonly cause ecchymosis, the common black and blue eye. This rapidly responds to daily intramuscular injections of 1.0 cc. of trypsin. The injection of 20 units of hyaluronidase into the discolored area will stimulate more rapid absorption of the blood. This is inadvisable, however, in aged and debilitated individuals, as it may produce more bleeding.

Simple lacerations of the skin may be closed with a 5-0 or 6-0 silk sutures. If the laceration is through the lash margin of the lid, one must approximate the cut distal edges, otherwise lid notching will occur. When the laceration is deep, the lid must be closed in layers. If the laceration extends though the conjunctiva, the cut ends of the sutures should be buried within the lid, otherwise they will abrade the cornea. If the laceration is between the punctum and the nose, one should ascertain if the lacrimal canaliculus is severed, as this calls for specialized care. If an ophthalmologist is not available, the physician should attempt to push a fine wire, polyethylene tubing, or stiff catgut suture through the punctum and then out the cut end of the canaliculus and into its other cut end as far as possible. Because of its delicacy, loss of any appreciable amount of lid skin demands plastic surgery to prevent lid distortion with eversion of the lash margins and consequent tearing and discomfort, or inversion of the lash margins with resultant denuding and scarring of the cornea. Partially severed ocular tissues which hang down, as, for example, the edge of an eyelid with its lashes, and are almost completely separated from the rest of the lid, will often retake with amazing rapidity. One should not do extensive debridement or excise such dangling tissue areas unless he is sure of his ground.

Conjunctiva and Cornea.—Small lacerations of the conjunctiva need not be sutured. Any laceration of the conjunctiva means that a penetrating injury must be ruled out. Chemicals which enter the conjunctival sac must be removed immediately by copious irrigation. Solid chemical particles which remain must be removed with fine forceps. This is especially true of lime and plaster. One should thoroughly irrigate the area of the upper cul de sac. Corneal and conjunctival injuries are similar when chemicals are involved. Acids tend to cause immediate, usually localized, non-progressive tissue necrosis. Alkali burns, such as those due to plaster and lime, are dangerous and progressive, especially if any residual particles are not removed. At this point, it must be emphasized that neutralization of chemicals is passe. One no longer waits to neutralize a chemical, but washes it out as rapidly as possible. The patient's eye should be irrigated promptly at the work site with water from a pan, bucket, hose or any other handy source of supply, or his head should be held

in a bucket of water, or under a running tap with the lids forcibly held open.

Corneal burns heal more rapidly under the influence of topical steroids. Chemical gases may penetrate the cornea and enter the globe, necessitating paracentesis of the anterior chamber. This procedure demands the attention of an ophthalmologist. The danger of this type of injury should be borne in mind.

When chemicals enter the cul de sac, they may create adhesions between the abraded conjunctiva and the cornea. These should be prevented by: (1) instilling bland ointments between the lids, (2) avoiding complete immobilization of the eye for long periods, and (3) by putting a shape-retaining conformer made of dental wax or some similar material into the cul de sac if the burn is severe.

Occasionally, contaminated foreign material in the cul de sac will result in an internal (meibomianitis) or external (hordeolum) sty after several days.

It is the physician's aim to control pain, remove foreign substances, stimulate healing, or at least not interfere with it, prevent anatomic distortions, and produce maximal visual recovery. To that end, topical anesthesia is used when the patient is first seen, but as infrequently as possible thereafter. It is better to give the patient some holocaine and epinephrine ointment to be used sparingly at night rather than to have him awaken you because of pain. Where intense lid spasm is present, the anesthetic will enable the patient to open his own eyes and to co-operate with the physician. Topical anesthetics tend to delay healing and should therefore be used sparingly. Antibiotic ointments also tend to interfere with healing and should be used only if infection is present or feared. One should never put any medication into the eye just for the sake of doing something. Topical steroids are not indicated after the removal of simple corneal foreign bodies and may be deleterious in the event that herpes simplex virus is present. In keratitis following reaction to incomplete rust ring removal, steroids minimize reactions. Contamination in the physician's office may result in infection of the wound and possible loss of the eye. One should use sterile solutions and instruments. This means that one should not have his solutions made up by the druggist, but should buy already prepared sterile products.

Metallic foreign bodies are usually associated with rust rings. The foreign body can be lifted out with the tip of a sterile cataract knife, a corneal spud, or a hypodermic needle, using focal illumination and magnification. If the foreign body is deep in the cornea, it should be removed by an ophthalmologist. Do not mistake an iris freckle for a corneal foreign body. The eye should be patched after a corneal foreign body has been removed.

Removal of rust rings is difficult and usually requires the use of a slit lamp. At times, one can touch the area of the rust ring gently with 1 per cent silver nitrate on the tip of a tightly wrapped applicator. The eye should then be patched for 24 hours. The next day the whole area can usually be lifted out with the sharply pointed end of a narrow knife or a needle. It is not advisable, however, for a nonophthalmologist to employ silver nitrate on the cornea and this procedure should not be attempted except in emergency situations.

Occasionally, one will see a large number of foreign bodies in a cornea. When it is evident that attempted removal of these foreign bodies, especially in the pupillary area, might result in considerable corneal scarring and consequent loss of vision, it may be wise to wait and to allow the foreign bodies to extrude themselves. This advice does not apply, however, to metallic foreign bodies, since these should always be removed as promptly as possible. I have seen two cases in which the corneas were spattered with hundreds of foreign bodies as a result of backfire during target practice. In both cases, the foreign bodies extruded spontaneously over a period of months. Attempts at removal would have resulted in considerable visual loss, as a result of corneal scarring caused by the instrumentation.

If a protruding foreign body has penetrated through the cornea into the anterior chamber, it is best not to attempt removal, but to refer the case immediately to an ophthalmologist. Frequently, attempts to remove these protruding foreign bodies result in breaking them off, thus rendering later removal difficult.

Corneal abrasions rarely require more than a cleansing irrigation and a tight pressure patch for 24 to 48 hours. A double eye pad should be affixed with multiple strips of firmly placed adhesive tape to produce the desired pressure immobilization of the abraded globe.

When the attending physician cannot handle a

corneal injury or estimate its gravity, the eye should be patched and thus immobilized until more expert attention can be secured. If the injury is a penetrating one, both eyes should be patched. Corneal lacerations may require suturing. Impact or lacerating injuries to the cornea demand ophthalmoscopic examination to rule out hemorrhage, retinal edema, or detachment. Blows to the eyes may produce ruptures of the choroid which are seen as semilunar, white rings concentric and usually temporal to the optic nerve. Traumatic anterior chamber hemorrhages tend to be recurrent and may produce secondary glaucoma.

Penetrating wounds of the cornea are always potentially dangerous, especially if they have perforated the lens or iris. One should note the depth of the anterior chamber by comparing it to the other eye. If a pupil is irregular or protrudes through the laceration, an ophthalmologist should be consulted immediately. One should avoid the error of trying to wipe a blood clot away from a wound only to discover that it is a prolapsed iris. If the services of an ophthalmologist are not available when the iris is prolapsed, the prolapsed portion should be excised with sterile scissors, after which a cycloplegic such as atropine should be instilled.

Deep injuries of the cornea and iris are accompanied by iritis.

Burns

Flash burns and ultraviolet radiation burns of the cornea rarely cause any serious problem except for the initial discomfort and lid spasm which may last several days. Burns due to boiling water, flames, or hot grease which have not caused serious corneal damage also belong in this category. A drop of topical anesthetic should be immediately instilled into the eye of the victim to show him that he can open his lids and that he has not been blinded. Such burns are best treated with cold compresses, holocaine and epinephrine ointment several times a day for the first few days, and a decongestant (ocular vyzine, ocular privine, phenylephrine ⅛ per cent) two or three times a day, and ample reassurance. Lid burns are treated in the same manner as skin burns elsewhere.

In these days of potential atomic warfare, it is advisable for the physician to know something about ocular injuries during atomic attack. Byrnes[1] and his co-workers have shown that it is possible for an eye which is facing in the direction of the exploding weapon to suffer injury when it is as far as 45 miles away from the blast. While the eye represents a relatively small portion of the total body area, its injury rate may be out of all proportion to its size. External eye burns due to atomic radiation are very much like burns from other causes. The one difference is that because the blink reflex is much slower than the speed of the light delivered by the atomic flash, the inside of the eyeball may be burned before the blink reflex can close the lids. The atomic energy which is delivered to the inner eye through the open pupil results in a choroidal burn. This is permanently damaging and very little can be done for it. At the time of the burn, there is considerable edema of the surrounding retina and choroid. It is probable that the immediate systemic administration of a large dose of ACTH or of one of the steroids would prevent much of the damage due to the edema itself. The size of the pupil controls the amount of damage suffered by the inner eye. All other things being equal, including the distance from the exploding atomic weapon, if the damage takes place in the daytime when the pupil is normally narrower, less light intensity is delivered to the inside of the globe. If the explosion occurs at night when the pupil is normally dilated, the damage is likely to be much more severe. The moral, then, is to avoid being anywhere near an exploding atomic weapon. But, if you are and you cannot get to a safe place, arrange to be exposed in the daytime and to face in a direction opposite than from which the blast comes and to keep your eyes closed. One is apt to be lulled into false security by being many miles away from the explosion. As Byrnes has shown, this security becomes less with each increase in potency of atomic weapons.

Conclusion and Summary

The various ocular traumata which the nonophthalmologist is commonly apt to encounter have been discussed, together with their management. In the main, this is one field where prevention through safety measures and prompt attention to rational first aid is often worth more than later attempts at cure.

Hypnosis in General Practice

FRANK J. BONELLO, M.D.
Saint Paul, Minnesota

The Mechanism of Neurosis

Some typical nervous symptoms

'pressure' in head	bladder
migraine	bowel } disorders
headaches	sexual } disorders
'full' or 'tight' feelings	menstrual } disorders
vertigo	tension etc.
trembling	'panic' feelings
sweatings	lack of concentration
blushing	(due to preoccupation
'flushes'	with own feelings)
palpitation	failing memory
breathlessness	(results from preoccupation
'sinking' feelings	with self and lack of attention)

From Van Pelt, S. J.: Medical Hypnosis Handbook, courtesy of Wilshire Book Company, Los Angeles, California.

MILTON[1] once wrote: "The mind is its own place, and in itself can make a Heaven of Hell, a Hell of Heaven." Probaby no two lines could express more fully the problem of neurosis in medicine, for in the neurotic it is the working of the mind and the imagination, combined with fear and anxiety, that creates the symptoms and signs which make life one continual torment of suffering.

All of us in practice are confronted daily by the person, who, in spite of multiple or systematic complaints, fails to present a pathological picture that can be interpreted as organic. Lewis,[2] at Johns Hopkins Hospital, in a report of 163 care-

fully studied consecutive patients, found 49 per cent had only psychogenic disorders and 27 per cent represented a combination of psychic and somatic processes. Thus 76 per cent of the patients were suffering wholly or in part from emotionally determined disease. The medical problems were predominantly chronic in nature and usually not severe enough to require hospital care but sufficiently severe to warrant some medical attention. In the average general practitioner's practice, this percentage will follow very closely. If one eliminates the common infectious processes, it will be found that approximately 60 per cent to 70 per cent of all patients seen have psychogenic illness, either pure or admixed with certain organic factors. What therapy have we for these patients?

John Schindler[3] once stated, "Our therapy for neurosis is no better today than it was 3000 years ago." In spite of the numerous and varied tranquilizers and sedatives, the neurotic still continues to plague us almost daily with his irrational and sometimes illogical symptoms.

In a study by Weiss and English[4] of the so-called "thick chart" patients (i.e., patients from the outpatient department selected solely on the basis of having a chart an inch or more thick) they coined a new phrase to replace "the high cost of psychiatry;" it was "the high cost of no psychiatry." Patients who accumulated these thick charts often had made dozens of visits with numerous referrals to specialty clinics involving hundreds of dollars worth of laboratory work and x-rays, innumerable prescriptions for placebos and barbiturates, and often, unnecessary surgery as well. Their illness frequently could have been better understood by an hour's interview conducted along psychosomatic lines.

In the evolution of the study of psychiatric health, Freud, of course, deserves credit for the great initial stride. His concept of the continual battle between the id, the ego, the super-ego and the environment, which is the basis of all neurotic illness, is familiar to us all. In 1885, Freud[5] began the use of hypnosis but soon abandoned it because of his inability to hypnotize most patients into a deep enough state to make analysis feasible. His attitude toward hypnosis was one of avoidance rather than outright rejection. His honest and open admission of confusion and ambivalence with regard to hypnosis is to his credit as a scientist.[6] All of Freud's pupils continually felt that psychoanalysis was too long, too detailed, and too expensive for the average individual and that shorter techniques of psychotherapy were indicated. Meyer's School of Psychobiologic Therapy has shortened psychotherapy and psychoanalysis immensely. However, this requires a fully coordinated and systematic review of the patient's entire biologic, psychic, and physical systems and is still too long and too expensive for the average individual. Now then, what other techniques do we have?

Van Pelt[7] in England, has put forth a theory of neurosis which is based on fear—either real or imaginary, which if implanted in the mind, concentrated with emotion, invariably gives rise to a tension state. Tension, of course, gives rise to symptoms on the basis of autonomic stimulation. The symptoms cause additional unpleasant sensations and worry which in turn causes more fear. This cycle is repeated over and over again. The original fear may have long ago been forgotten but the symptoms are promulgated by the constant vicious cycle of tension and fear. For example, fear may cause palpitation which in turn may give rise to further fear on the basis of a suspicion of heart disease. This latter fear gives rise to additional tension, which, of course, reactivates the palpitation. Symptoms of palpitation and subsequent insomnia may in turn give rise to increased fear and anxiety which only aggravate the symptoms so that a vicious cycle is established. On the basis of this one cycle alone, all of the various findings which could be symptomatic of neurosis can be found. (See diagram).

Selye,[8] in his study of adaptation and stress, has noted the fact that emotional turmoil gives rise to the most prolonged form of stress reaction of almost any illness. In emotion, the constant tension and fear continue to stimulate the pituitary-adrenocortical reaction which continues to produce the signs and symptoms of stress and alarm reaction. Within the past several years, studies have been done which are beginning to point to the fact that asthma, rheumatoid arthritis, and rheumatoid diseases, habitual abortion in women, and other of the so-called stress diseases may fall, at least in part, in the psychosomatic realm. Considerably more research will, of necessity, have to be done before any conclusions can be drawn.

Estabrooks[9] has advanced another theory in which he believes that mental disease is basically due to repression, which is in reality, a post-hypnotic suggestion given on the basis of auto-hypnosis or auto-suggestion. This complex is imposed

by life itself—is not under any kind of control, and probably dates back to an early age. The psychiatrist in dealing with the patient is confronted with a post-hypnotic suggestion to be sure, but it is a very different post-hypnotic suggestion from that which he could produce in his laboratory merely to demonstrate a point. He can guarantee to remove his laboratory post-hypnotic suggestion at a moment's notice with no harm done. He can make no such guarantee in the case of the Freudian complex. The two characteristics of the Freudian complex, namely, emotional conflict and time duration, cause the personality to erect extreme resistances to any change. Therefore, how do we treat these emotional illnesses? The basic concept is simple. The best way, as we well know, to rob a post-hypnotic suggestion of its compulsive power, is to bring it into consciousness. This puts an end to the process of unconscious motivation, for the complex in the post-hypnotic suggestion is now a part of our normal conscious life. However, the techniques involved are extremely difficult and occasionally impossible.

If one reviews the cycle as set up by Van Pelt, it is obvious that, analytically, in order to remove all of the tension it becomes necessary to go back and remove the basic fear. Van Pelt[7] has shown that by hypnotic recall, it is frequently possible to bring the original precipitating fear back into consciousness. This serves to remove the unconscious motivation producing the patient's symptoms. A thorough discussion and reintegration of these experiences into consciousness in many instances will result in an amelioration or complete disappearance of symptoms.

For the most part, the use of hypnosis in medical practice will be limited to the treatment of disorders in which symptoms play minor defensive roles. In treating patients under hypnosis we attempt to use the same type of procedures we would use in the waking state of psychotherapy, namely, reassurance, re-education, persuasion, direct symptom removal, treatment through psychobiologic techniques, and lastly, reconstructive therapy, or therapy directed at reconstructing the entire personality, which would be based on deep hypno-analytic techniques. For the most part, for our use in general practice, we will confine ourselves to symptom removal, symptom amelioration, symptom displacement, re-education, persuasion and reassurance. Using these techniques alone, fully 60 per cent to 70 per cent of all neurotic illness will improve under direct hypnotic suggestion. Erickson[12-17] has written extensively on these techniques and reference to his methods are invaluable to anyone employing hypnotherapy.

One criticism which many have to the hypnotic removal of symptoms is that it attempts to remove the symptoms without getting at the basic underlying cause of the illness and that therefore, it removes the symptoms but leaves the neurotic personality intact. However, in actuality, it seems that the very persons who would decry such symptom removal are the same men who would prescribe ergotamine for migraine, barbiturates for tension headache, corticosteroids for asthma, antispasmodics and antacids for gastric neurosis, et cetera, without attempting to get at the underlying psychological conflict. What difference is it then, if we can remove tension headaches by teaching a process of relaxation rather than by giving repeated doses of a barbiturate?

The list of conditions in which hypnosis may be used is legion. It may be used both in the treatment of functional and organic disease, and anyone interested in its use in general medical patients is referred to the works of Bernheim[10] and Bramwell[11] who used it successfully in almost every syndrome reported. For our own use and for our description, we are going to take just a few conditions and state briefly some of the results which have been attained and list certain cases which demonstrate its effectiveness.

Psychoneurosis

Probably nowhere has hypnosis been more extensively used than in the treatment of the psychoneuroses and their attendant somatic symptomatology. Its use in these syndromes is either in the form of authoritative direct symptom removal, which has in many instances given remarkable and prolonged results, or in combination with persuasion, re-education, reassurance and other simple psycho-therapeutic techniques. The following cases illustrate some of the techniques which have been used.

Case 1. Mrs. W., a thirty-two-year-old housewife, has suffered for the past four and one half years from moderate insomnia, extreme nervousness, spells of extreme jitteriness, general bodily discomfort, occasional headaches, heartburn and numerous attacks of palpitation numbering up to ten to twelve daily. These were accompanied by anterior chest pain, dyspnea and a general feeling of nervousness. She had been studied repeatedly for organic illness and none had been found. Her thera-

pies had been numerous and varied without significant response. The patient stated that her symptoms began when her child developed diabetes. At that time she became nervous, apprehensive and fearful. Physical examination at the time of her first examination was entirely negative other than showing the findings of apprehension, precordial tenderness and sweaty palms. The patient complained subjectively of pain in her chest and her right shoulder. Under a guise of relaxation, the patient was hypnotized and achieved a deep trance in less than two minutes. Her symptoms were explained to her as a reaction to fear over her child and that in view of the fact that her child was considerably better now she no longer needed them. The patient was then allowed to sleep for ten minutes and awakened. She awakened without the pain in her chest or her shoulder, stated that she was sorry that she had fallen asleep and was discharged. She was seen ten days later at which time she had had two minor episodes of palpitation but had otherwise felt extremely well. She has been followed over the past eight months and is at present asymptomatic except for very slight fullness in her throat when under stress.

Case 2. This patient is a twenty-two-year-old woman who has had recurrent right lower quadrant pain for approximately six years. The pain was almost continuous in nature although periodically would increase to a point where she would have difficulty in walking. She had been advised by three physicians to have an appendectomy. During a period of two years while the patient was under my care, she complained of pain recurrently every four to five weeks. Physical examination, laboratory studies and x-ray examination were all entirely negative and the patient's response to all therapeutic regimens was poor. The patient was hypnotized with her consent and asked to recall the first time that she had this pain. She stated that she was thirteen, that she had gone out with a boy who was considerably older than her and that her father had suspected her of sexual indiscretion and had taken her to a doctor. Following this, she stated the pain occurred, lasted a short time and then subsided. However, at the age of sixteen she became pregnant illegitimately and had a spontaneous abortion after a toboggan accident. It was shortly after this that her pain became more intense. She suffered severe feelings of guilt and anxiety over the pregnancy and abortion and stated that she felt that this pain was her punishment.

Although no further attempts were made to explain the underlying psychodynamics or to elicit other dynamics of her illness, the pain subsided within twenty-four hours after hypnotic therapy and the patient has been entirely free of any discomfort over the past eight months.

Case 3. The patient is a twenty-six-year-old man who first consulted me because of periodic indigestion, upper abdominal pain after eating and a burning feeling in the epigastrium of approximately six months' duration. It was becoming progressively worse. The patient was now suffering from large amounts of gas, belching, insomnia, but did not complain of overt nervousness. Physical examination revealed epigastric tenderness but was otherwise essentially negative. No radiologic examination was done. Inquiry into emotional factors which may have been responsible for the pain were entirely without avail. The patient was placed on an ulcer routine and observed over a two-week period. He noticed slight improvement but the symptoms and insomnia persisted.

Under a guise of relaxation, the patient was hypnotized but only a light trance achieved. A single statement was made to the patient as follows: "Perhaps there is something that is bothering you that you have not entirely been aware of or that you haven't told me which might be responsible for your symptoms." Without awakening, the patient immediately poured out a tirade of resentment and hostility toward his employer and the people with whom he worked feeling very resentful of the fact that he deserved more financial remuneration for what he was doing. His job carried considerable responsibility without commensurate financial compensation. During a period of twenty-five minutes, the patient gave vent to his feelings of indignation. Following this, an explanation of the dynamics of the conversion of his resentment into symptoms (utilizing ordinary organ language comparisons) was given in both the hypnotic and subsequently on the waking level. In spite of no suggestions as to his continuing therapy, the patient stopped the medication and the following day went back to his normal diet and has been asymptomatic for the past six months.

It is readily apparent to anyone familiar with the psychodynamics of emotional illness and with psychoanalysis that the above interpretations and explanation of illness are on an extremely superficial level. However, it has been surprising to me that the results, using even superficial analytic types of interpretations as those noted above, have been very successful in removing a large number of psychosomatic symptoms without re-precipitating other new and different symptoms, and that the need for deep analysis has been unnecessary in most of the patients seen.

Epileptoid Seizures

The question of whether epilepsy or atypical epilepsy can represent psychogenic illness has become apparent within recent years. Numerous reports have appeared in the literature in which atypical epileptic seizures have been relieved or considerably ameliorated by hypnosis or psychotherapy.[18-20] Rosen[21] has reported a case of a woman with severe epileptic seizures of Jacksonian type, who had two cranial explorations because of her symptomatology. Her entire picture was based on psychogenic causes and was relieved by hypnotic therapy. The following case demonstrates

an atypical epileptic picture which responded almost dramatically to hypnosis.

Case 4. A. H., a seven-year-old boy, when seen had had seizures over a period of approximately nine to ten months during which time he would become incoherent and scream and act rather wild. The child would occasionally fall in a fit and would sometimes run into objects as if he did not see them. There appeared to be momentary lapses of consciousness. The spells had become progressively worse and more numerous. He complained of some headaches over the occipital area of the skull.

Physical examination, neurologic examination, routine laboratory and x-ray studies were entirely negative. Neurologic consultation substantiated a diagnosis of possible petit mal seizures with psychomotor varient. An electroencephalogram was reported as diffusely abnormal but non-localizing. All other studies were entirely negative.

The patient was hospitalized and during three days of hospitalization had no seizures although he would become somewhat hyperkinetic before visiting hours. He was hypnotized on two occasions and seizures were precipitated under hypnosis. He was then asked to define the feeling which he really had. He stated that he was angry at his father and mother for the way they treated him. It was obvious from conversation that there were deep underlying hostile feelings toward his parents who had totally rejected him. Under hypnosis, an explanation of his feelings was given to the child in language that he could understand and it was suggested that perhaps his problems could be resolved in a somewhat more satisfactory manner than in the manner in which he was attempting to solve them. He was told that he could find other less frightening ways of expressing his hostility. No further therapy was done and yet the child has remained entirely free of seizures, has been considerably less nervous and has improved remarkably in school over the past two years.

Two other patients with atypical epileptic seizures, both of whom had been under the care of neurologists, have been treated over the past six months. Both have been found, on analysis, to represent a discharge of underlying feelings in the form of "acting out" and both have responded dramatically to a rather superficial insight therapeutic regime."

Musculo-Fascial Syndromes

Over the past several months, hypnosis has been used in the treatment of eight cases of lower back pain, bursitis, mild fasciitis, all of which failed to respond to ordinary conservative methods of therapy for periods of up to eight weeks. No case was treated with hypnosis which had not had at least ten to fourteen days of ordinary conservative therapy. In this it was hoped that the patient would serve as his own control for the results. In most cases the symptoms were becoming progressively worse rather than better at the time that hypnosis was first attempted.

After hypnotic therapy was begun, improvement was noted within twenty-four to forty-eight hours in almost every case and this improvement was progressive.

Case 5. The patient is a thirty-five-year-old woman who had had a backache of nine and one half years' duration which had begun shortly after the birth of her second child. She had been treated by eight different doctors during that period of time and a multitude of therapeutic techniques had been used, all without success.

Utilizing hypno-analytic techniques, it was found that the patient's backache represented a tremendous amount of self-directed hostility which because of rigid personality factors could not be directed into other more normal channels. Following the development of rather superficial insight into the reason for her backache, the patient's pain cleared spontaneously and she has been free of discomfort for the past seven months.

In most other cases no analysis of underlying emotional factors was undertaken and the only suggestions given were that there would be a progressive increase in relaxation with a corresponding diminution of the amount of discomfort until the discomfort would cease to exist altogether. The patient's response to therapy in all cases was rather remarkable, the improvement being progressive and complete in every case.

Surgery

Hypnosis has been used in the preoperative preparation of the patient for surgery, both to relieve the anxiety caused by the anticipation of surgery, and for the purpose of relieving part of the postoperative discomfort. In a separate study done by the author and co-workers[22] at the University of Minnesota, it was found that preoperative hypnosis and suggestions of comfort after surgery resulted in 55 per cent lessening of the amount of narcosis required. Perhaps a better view is obtained when six consecutive patients having had a cholecystectomy are cited. Of these, two control patients received eight and eleven doses of narcotics postoperatively, while four hypnosis patients received none, one, two, and four doses, respectively.

In my own practice, hypnosis has been used as an adjunct to surgical therapy in numerous pa-

tients. In adult patients undergoing tonsillectomy under local anesthesia, it has been found that by hypnotic augmentation of anesthesia, bleeding has been controlled in almost every case, and post-operative discomfort has been minimal to entirely non-existent. A traumatic laceration of the ulnar nerve was repaired under hypnotic anesthesia, alone, in an apprehensive young woman sixteen years of age. Another young girl, who had sustained a complete severance of the flexor tendons of the left fifth finger, underwent the entire operative procedure of tendon repair using a minimal amount of local anesthesia and hypnotic relaxation. In one patient who desired hypnosis as the sole anesthetic during surgery for a thyroid adenoma, hypnotic anesthesia was attempted but could not be obtained even after five hours of intensive hypnotic training. The patient was advised, however, that although her hypnotic anesthesia could not be used for the surgery itself that it would be effective in the postoperative phase. Therefore, she had the thyroid adenoma removed under pentothal anesthesia with strong preoperative suggestions that she would have no postoperative pain. Following surgery, the patient was awake within one hour, within two hours had eaten a full meal, had absolutely no discomfort during her postoperative period in spite of a minor wound infection, and was discharged from the hospital entirely asymptomatic three days after surgery.

A major factor in the preoperative use of hypnosis is the fact that although the relative amount of narcosis in any individual case may not be substantially altered, the patient will, nevertheless, readily admit that he feels considerably better than he had anticipated. In several cases, a good evaluation has been possible where the same patient has had preoperative hypnosis for one operation and has had other surgery done without hypnosis. In these particular cases, the comments of the patients were extremely rewarding.

Obstetrics

The use of hypnosis in the preparation for delivery has, within recent years, greatly increased in popularity notably through the efforts of Kroger and DeLee,[23] Abramson and Heron,[24] and Clark,[25] who by their reports of its success have prompted others to use it. Its effectiveness in this field is measured primarily by its ability to diminish the amount of analgesia and narcosis during obstetrical labor and delivery; by the moderate to marked shortening of labor; and the increased sense of comfort to the patient. In occasional instances, with a good hypnotic subject, spectacular results will be reported. However, in the vast majority, although discomfort persists, the patient becomes able to tolerate it and to remain rather placid during delivery, requiring much less narcotics than the non-hypnotized subject.

In my own practice, teaching has been given to the patients as a group which meets every other week for approximately two hours. During these sessions, the patient is trained in the development of the hypnotic and auto-hypnotic state, using a technique modified from that of Clark. Suggestions are given for a diminished amount of fear, for increased sense of relaxation during labor and delivery, and for a relative amount of analgesia and anesthesia. Patients are trained in the technique for inducing an auto-hypnotic state, to be used at their own discretion, during labor. It must be understood that group hypnosis will in no way achieve the results that can be obtained with intensive individual instruction. However, the time which one can devote to this type of training is markedly limited in a busy general practice and one must be willing to settle for somewhat less than optimal results.

Hypnosis has been used to date in a total of fifty-three patients and its results are summarized in Table I along with a control group of fifty-five patients. No attempt was made to separate the first and second stages of labor in these patients and both stages are grouped in the total time. In the report published by Abramson and Heron[24] it was noted that, in both the trained and the untrained subjects, the second stage comprised 35.8 minutes and 34.8 minutes, respectively, so that the second stage of labor has shown relatively little difference in the trained and the untrained patients. The longest labor in the hypnotic group was twenty-three hours. In the untrained group,

TABLE I. RESULTS OF HYPNOSIS IN LABOR

	No. of Patients	Mean Duration of Labor (1st & 2nd stage)	Mean Amount Demerol Per Patient
Primipara			
(Hypnosis)	18	9.9 hours	73.3 mg.
(No hypnosis)	13	16.2 hours	91.1 mg.
Multipara			
(Hypnosis)	35	5.65 hours	23.6 mg.
(No hypnosis)	42	7.07 hours	62.0 mg.

there were two labors of slightly over thirty-eight hours.

It is interesting to note that in the thirty-five multipara who delivered under hypnosis, twenty-five took no analgesia at all; whereas, in the control group of forty-two patients only eleven were able to go through labor and delivery without analgesia.

The testimony and comments of the individual patient have probably done more to increase the popularity of hypnosis in my own particular practice than any other factor. These patients have, for the most part, been extremely grateful and have felt that hypnosis has not only helped them with their labor but this increased training in relaxation has helped them with their subsequent tensions and anxieties.

Summary

Although the use of hypnosis in medical therapy may still be considered in its infancy, nevertheless, the results obtained cannot be denied. Although not advised as a panacea, it is felt that its use as an adjunct to orthodox medical therapy will result in improvement of the entire therapeutic regimen. As with other modalities of therapy, discretion must be exercised at all times and patients picked with considerable care. It is only by such measures of approach that hypnosis will prove its worth as a medical tool and will not again be relegated to oblivion as has so frequently happened in past centuries.

Endogenous and Exogenous Materials Used in Repair of Large Hernial Defects

Review of the Literature

● *Repair of a simple uncomplicated hernia, while not necessarily a thing of beauty, may be a procedure of joy to the surgeon. Conversely, attempts to repair large recurrent hernial defects may give rise to the greatest vituperation and perspiration ever heard and seen in the operating room. This is an interesting review of the use of various materials to repair such appalling defects.*

Publication sponsored by Dr. J. H. Grindlay, Section of Surgical Research, and Dr. J. M. Waugh, Section of Surgery, Mayo Clinic.

CARL R. BRUNSTING, M.D.
Rochester, Minnesota

Fellow in Surgery, Mayo Foundation, Rochester, Minnesota.

THE belief that all hernias are curable has kept surgeons searching for the ideal hernia repair, that is, the perfect cure. New technics, new methods and new materials have been described in an endless parade of "reviews" and "series." Yet the subject is never dead. Recurrent hernias, because they represent such an obvious failure to achieve ideal treatment, are a particular challenge. Each operative repair compounds the reparative problem, to say nothing of the patient's misgivings. No challenge in this field is greater than the repair of the extremely large, recurrent hernial defect.

The great majority of herniorrhaphies involve small inguinal hernias. A lesser proportion are repairs of large inguinal hernias and most of the incisional and other ventral hernias. An extremely small number, certainly less than 5 per cent, deal with those massive muscular faults which may be incisional, congenital (usually umbilical or para-umbilical), or the result of previous removal, as in wide excision for cancer, and which are almost always veterans of attempted repair. These few require the additional support of prostheses, or grafts.

This discussion is focused on the various endogenous and exogenous materials used as grafts in the repair of these uncommonly large hernias.

The basic weakness in a hernia is in the fascia and muscle. This extensive loss must be replaced and the abdominal wall must be reconstructed. Redundant tissue is usually present in these great bulges, but it is weak; it is attenuated aponeurosis or merely the stretched scar tissue resulting from a prior operation. When the hiatus between the stronger peripheral layers is more than 8 or 10 cm. in length and when the patient is obese, a patch is necessary to bridge the gap. Herniorrhaphies using relaxing incisions or the turning of fascial flaps, either pedicled or free, may only displace the basic weakness.

Not only is the wall rebuilt, then, but the use of the graft obviates excessive tension in bringing together the strongest remnants of the abdomen.

This in itself is a complex problem. On the one hand, the placing of deep sutures under tension is a violation of a fundamental surgical principle. On the other hand, it is well known that wounds which heal under tension are more resilient, because the fibrous scar aligns itself against the greatest stress. Sutures must share equally the burden of closure. The graft ideally distributes tension evenly, at something less than the critical force, with enough immediate strength to withstand breakdown postoperatively and enough durability to serve as a scaffold on which the body constructs its own directional scar.

Historical Developments

The history of this aspect of surgery is colorful. The old "stone and rupture cutters" were highly original men who wrote extensively and often heatedly extolling their own choice of suture material and technique. Some of the best-known surgeons have cut their teeth on hernias. W. J. Mayo[1] published his radical cure of umbilical hernia by the transverse overlap method, which involved extending the hernial hiatus sharply and then overlapping successive fascial layers much as in buttoning a double-breasted coat. This foresaw the next step in herniology, namely the swinging of re-enforcing fascial flaps. Halsted[2] claimed to have first described this procedure in inguinal herniorrhaphy. He said, "The anterior sheath of the rectus muscle might be employed . . . whenever the conjoined tendon is insufficient. . . ." Incidentally, he gave some credit to his then house officer, Harvey Cushing, for making a sketch of the method.

These innovations opened the door to a new era of surgical reconstruction of the abdominal wall. Billroth reflected the creative thinking of the times in a prophetic statement, which was quoted from Czerny by Halsted[2]: "If we could artificially produce tissues of the density and toughness of fascia and tendon, the secret of the radical cure of hernia would be discovered."

Kirschner,[3] in 1909, showed that autoplastic grafts of fascia lata remained viable when transplanted, and Gallie, in 1930, demonstrated their practical value in ventral herniorrhaphy. Wangensteen,[4] in 1934, and many others since have written convincingly of the use of fascia lata as onlay or, better, inlay grafts. Masson[5] pointed out that strips of this fascia, cut from the iliotibial tract with his stripper, could serve as "living sutures." Dermal and "cutis" grafts were first used in the early 1900's by Loewe,[6] Rehn[7] and others, and were first utilized in this country in the 1930's; these have been only transiently in vogue in the United States, as compared with a more widespread acceptance in Europe and South America.

Metals of all kinds have been tried in reconstructive surgery ever since gold was used in repair of a cleft palate centuries ago. Phelps,[8] in 1894, tried coiled silver wire, and Witzel,[9] in 1900, used ready-made silver mesh in attempting to patch up large hernias. For a time, silver and some other metals were thought to have bactericidal activity in the body, but of course these operations failed. Stainless-steel mesh and chain nets or filigrees were introduced into hernia repair in the late 1930's. Tantalum, suggested by Burke[10] in 1940 as a suitable prosthetic element, became generally available in the United States in 1945. Throckmorton,[11] Koontz,[12] and Lam and associates[13] published encouraging preliminary reports in 1948. Finally, the use of synthetic materials, including nylon, teflon, dacron (or mersilene), ivalon sponge, silicone products and others is being reported now at an almost feverish rate.

The Ideal Material for Repair

Obviously, the ideal graft is first of all functional. The graft is a "patch" only insofar as it becomes a functioning part of the body. Other good qualities, such as availability, ease of sterilization and cost are secondary. Naturally, no list is complete in describing the best of all possible graft materials; no one can predict what late unfavorable side effects may arise, nor can one ever define perfection. Cumberland[14] made a workable starting list and is usually quoted on what constitutes a nearly ideal graft for the abdominal wall. He said:

1. The prosthesis must be relatively inert in the tissues. . . .
2. The material used should be easily sterilized.
3. It should be durable and should provide a supporting framework for a sufficiently long time to allow the formation of a firm and stable fibrous tissue matrix to provide a permanent cure of the hernia.
4. The material should be relatively elastic so that it may respond to deforming forces, such as muscle contraction, coughing and sneezing, without tearing of its attachments to the patient's tissues.

5. It is preferable that the borders of the material should be smooth. . . .
6. It should be radio-translucent. . . .
7. The prosthesis should be readily obtainable and economical.

He had good results using a prefabricated nylon prosthesis.

Some excellent experimental work has been done in evaluating the newer materials, such as tracing serially the tensile strength of the repair as the graft is gradually replaced by connective tissue. Attempts have been made to predict disadvantages, such as subsequent weakening of synthetic materials through depolymerization, late calcium deposits, or even potential carcinogenic effects. Since no one yet has adequately compared different materials using the same technique in groups of similar patients, it appears that we must wait for the much slower and less satisfactory type of proof, namely the accumulation of an impressive quantity of successful repairs.

Fascial Grafts

Fascia lata from the patient's own thigh has proved its functional worth in this way. Not only is the graft itself viable but, used in conjunction with inert materials, it becomes a source for the generation of new fibrous tissue. In 1957, Burton[15] stated that the use of generically related tissues, such as fascial grafts, generally gives the most satisfactory results. Against the regular use of such an autograft is the time-consuming and sometimes exacting process of trimming sufficiently large pieces from the thigh. Fascia also has a unidirectional force, which makes it theoretically less desirable in distributing tension and practically more difficult to suture. It is not currently in vogue, especially when compared with the synthetic materials, which have received such dramatic attention recently in vascular surgery. For example, a young surgeon now can safely remark, as Moloney[16] did in 1958, "Most surgeons have stopped damaging the thigh to secure fascia to repair the abdominal wall." It appears that the proved value of fascia lata is currently underestimated.

Heterografts, such as those from ox fascia, had sporadic success and were a nuisance.

Skin Grafts

Dermal and cutis and even full-thickness skin grafts have been used successfully; they actually take a more active part in the body's postoperative regenerative reaction than does fascia. Uihlein,[17] in one of the first articles in English on the subject, in 1939, pointed out the importance of suturing cutis grafts under tension, making a "taut drumhead," in order to provide the optimal functional stimulus to scar formation. However, these grafts are cumbersome to prepare and somewhat difficult to sterilize. In addition, cysts have been reported to originate from buried, skin-derived transplants, presumably arising in the stubbornly persistent sebaceous glands.

Metals

The metals, especially tantalum mesh, for a while appeared to be the most hopeful candidate for the best graft, and they are still in wide use. ReMine and White,[18] in reviewing thirty-one ventral herniorrhaphies at the Mayo Clinic up to 1953 using tantalum, found that 74 per cent of the patients who were followed were well and had no recurrence one to nine years later. The subsequent "work hardening" and late "fractures" of these metallic implants, which are so apparent roentgenologically, originally were thought to be of only academic importance. After all, the long-term results depend not so much on the graft itself as on the fibroblastic replacement of the graft. However, late recurrence has taken place, and the sharp edges of the broken metal have worked themselves deep, even to direct contact with the intestine. In 1956, Hultengren and Lindholm[19] reported incapacitating aching and stinging sensations in a small group of cases in which tantalum was used, but these effects have not been widely noted. As one can appreciate, the removal of any of these meshlike materials, which are only trellises encased in cicatricial concrete, is a heroic task, but it has been necessary when infection or draining sinuses persist.

Synthetics

The materials now receiving the greatest attention are the man-made synthetics and fabrics, such as nylon (used as a monofilamentous net or tricot[20]) and polyester fibers, the trade names of a few of which are Dacron (DuPont) and Mersilene (Ethicon). Surgical ivalon sponge, used in sheets 2 or 3 mm. thick, is easy to work with, presents few problems of fluid collection, and retains good strength after repair.[21] It does not have the readily demonstrable lightness and

strength of the other fabrics, however, which is perhaps more a poor selling point than a disadvantage. Preliminary clinical reports (often too preliminary) on these newer materials are extremely encouraging, but it is impossible from the current literature to evaluate their relative place in the repair of hernias.

Comment

The growing enthusiasm for such apparently ideal grafts is tempered by a lingering scepticism. The very conservative surgeons always have been distrustful of the implantation of foreign bodies. Many surgeons point out that unfavorable operative results do not appear in current publications and that the few reports of positive results have little statistical support and may be premature. Mayo and Keeley[22] suggested a five-year follow-up as a reasonable minimal period for first reporting recurrence rates. Many surgeons are understandably annoyed when they are confronted with the bad results of prosthetic surgery done elsewhere. In 1957, Maier[23] stated, "Sound surgical judgment is still the prime prerequisite of the good surgeon. It is my conviction that its absence has been clearly demonstrated in most of the patients who have come under my care following the use of these various implants, and their indiscriminate use in the repair of hernias should be condemned."

In 1957, Poth[24] discussed a paper on full-thickness skin implants, saying, "It is my impression that all too frequently and without justification, inert materials or free grafts are used to repair tissue defects. It has been my experience that sufficient tissues are available locally to effect adequate repair whether the defect is in the inguinal region or is a ventral hernia. Should it become necessary to use accessory tissue to bridge a defect, I should favor fascia taken from the patient's own thigh."

Therefore, with as little agreement as is evident concerning the repair of simple inguinal hernias, it is not surprising that even more heated controversy exists on the subject of ventral hernias. As knowledgeable a herniologist as McVay[25] was so disenchanted with the cure rate in these difficult cases that in 1956 he wrote, "The obese patient with a large incisional hernia . . . had better keep his hernia, for the second recurrence will undoubtedly be more troublesome than the first."

A Final Word

In closing a brief review of any subject, it is the custom to say that the next few years should add substantially to our knowledge. In this instance, it is difficult to be that hopeful. For one thing, ventral hernia is a disease of neglect on the part of the patient as well as the surgeon, for, as long as we recommend trusses and as long as we persist in making "unphysiologic" incisions and repair them poorly, we (or preferably some distant colleague) will be faced with recurrent and incisional herniation. Prevention is the ultimate answer, of course, and in this regard the control of obesity is of supreme importance. But even when the instance does arise, the basic surgical principles of asepsis, hemostasis and gentle handling with just the right degree of tension are all probably much more important than is the variety of material we may choose, or even exactly how we patch the gross defect. Although the race for the ideal graft and the perfect hernia repair appears to be advanced and dramatic, we are not likely to succeed unless we return to the basic and undramatic precepts that C. H. Mayo[26] referred to when he said, "Carry out the two fundamental surgical requirements: see what you are doing and leave a dry field."

Present-day Management of Hyperthyroidism

EDWARD S. JUDD, M.D.
From the Section of Surgery
Mayo Clinic, Rochester, Minnesota

The introduction of goitrogenic drugs and, later, of radioiodine in the treatment of toxic goiter was held by many to sound the death knell of the surgeon in this field. However, the surgeon is still very much alive.

Read at the Continuation Course, University of Minnesota, Minneapolis, January 22 to 24, 1959.

FOR a protracted period of time, the surgeon was considered the final authority in the management of toxic goiter following Kocher's ingenious development of the hemostat now known by his name. This aid enabled the surgeon to conduct the patient through thyroidectomy without fatal hemorrhage; consequently, following a more clear-cut understanding of the function of the recurrent laryngeal nerves and the physiology of the parathyroid glands, subtotal thyroidectomy became a standardized procedure that was conducted with variable risk to the patient throughout the civilized world. At first, the extremely toxic patient was sent to the operating room with some misgiving, because thoroughly effective preparatory agents were yet to be discovered. However, following the widespread adoption of iodides for preparation of the patient, the morbidity and mortality rates quickly decreased to a more acceptable level. The only problem from then on was to attempt to select patients who were sufficiently well that the majority of them might be expected to survive operation.

A rude awakening came to the surgical field in 1943, when the use of goitrogenic drugs was introduced as a possible replacement for surgical therapy. It appeared that a great challenge was being issued to the surgeon, in view of the fact that thyroidectomy perhaps would no longer be required. That the various forms of thiouracil and their refinements did not become the ultimate definitive therapeutic agent is obvious to most authorities at present.

Immediately after World War II, yet another dramatic development in the form of radioactive iodine posed a serious threat to the surgeon's formerly important position. It was stated, rather frankly, that surgical intervention no longer had any place in the treatment of toxic goiter. That this situation is not entirely true appears to be the point of departure at the present time. My surgical colleagues and I are still employing subtotal thyroidectomy when the occasion appears proper, and there is every reason to believe that we will continue to do so.

Types of Toxic Goiter

The late Dr. Henry S. Plummer impressed on both the internists and surgeons of the Mayo Clinic the importance of distinguishing between the two main types of hyperthyroidism. The "hypertrophic parenchymatous thyroid," associated with what is known as exophthalmic goiter, remains a distinct entity that has distinguishing characteristics peculiar to itself. The other category is classified as "hyperfunctioning adenomatous goiter." We continue to divide patients with hyperthyroidism into these separate categories.

The two main groups differ widely in some respects and less widely in others. The age groups are frequently greatly divergent. The response to medical measures, whether preoperative or definitive in nature, frequently is extremely different. The possibility of the ultimate development of malignancy in the thyroid gland has variable connotations, and the complications following partially treated or untreated goiters in these two groups can be strikingly different. Aside from the great contrast in the histologic appearance of these two forms of thyroidal disease, we note also a definite difference in the mortality rates, and more will be said about this later.

Disadvantages of Known Therapy

In considering treatment for toxic goiter, perhaps it is best to admit the shortcomings first in order to clarify the atmosphere in attempting to select what we think is the best treatment in any given case. Perhaps first and foremost among the drawbacks of any known therapy is the recurrence

rate of the original state of hyperthyroidism. It is known that use of iodine alone is followed by an extremely high recurrence rate, and we rarely employ it as the sole therapeutic agent. The goitrogenic drugs may be thoroughly effective in perhaps 50 per cent of the patients; however, recurrence of the original symptoms in the remaining 50 per cent of the patients is enough to stimulate search for some other method of treatment. We surgeons admit to at least a 5 per cent rate of recurrence after even a radical subtotal thyroidectomy. Conversely, however, a 95 per cent rate of relatively permanent remissions appears to be a highly satisfactory situation, and perhaps indicates that surgical treatment deserves careful consideration even in 1959.

Myxedema is considered by some authorities to be the logical end point for any form of treatment of the hyperfunctioning thyroid. It is certainly to be preferred to recurrent hyperthyroidism. We think that treatment need not be this cumbersome and that hyperthyroidism can be controlled permanently in a majority of patients without producing myxedema. We must admit to a myxedema rate of 10 to 15 per cent following thyroidectomy, but this condition is relatively easy to treat and has not posed any great concern. Myxedema following the use of goitrogenic drugs and radioiodine is seen in a much greater percentage of patients so treated.

The mortality rate is something that internists frequently look on as strictly for surgical discussion. As this is a surgically minded audience, we may be forgiven for dwelling on it in a little detail. The surgeon always will be quick to point out that any known treatment may have its own mortality rate. Untreated hyperthyroidism can be rapidly fatal. More often, incorrectly treated hyperthyroidism will not be immediately fatal but may well lead to complications beyond which there is no point of return. One must consider, also, the possibility that any nonsurgical treatment elected for a patient may have its own inherent mortality rate, so perhaps the subsequent brief consideration of surgical mortality may not be inappropriate.

Disadvantages of Surgical Treatment

The disadvantages that are peculiar to surgical treatment are few in number but are uppermost in the surgeon's mind. Perhaps first among these, because it is so obvious to the surgeon and his patient alike, is paralysis of the recurrent laryngeal nerve. It is impossible to know with any certainty what the incidence of this complication is at present. The more experienced a surgeon becomes, the more cognizant he is that, even in the most adept and practiced hands, injury to a recurrent laryngeal nerve is always possible. We have developed a method for thyroidectomy that leaves little or no excuse for bilateral permanent paralysis of the recurrent nerve, but we are well aware that an occasional patient still may sustain unilateral permanent palsy. This incidence is less than 1 per cent in our experience.

Permanent tetany is associated only with surgical treatment. Varying degrees of transitory tetany are demonstrated easily if one routinely searches for Chvostek's and Trousseau's signs in the early postoperative days. As long as difficulty with the airway or carpopedal spasm is absent, no particular treatment is required. When tetany is more severe, treatment may be rather complicated; in permanent tetany, therapy is complex, difficult, time-consuming and often extremely expensive. This is a serious complication, one that should not be minimized.

The morality rate following subtotal thyroidectomy is one feature concerning which we can be extremely objective. We have a modern series, with what appear to be significant statistics that will be discussed in a subsequent section of this paper.

Nonsurgical Methods of Treatment

As already mentioned, my associates and I have abandoned use of the goitrogens as definitive therapy in any routine fashion, as these agents have been disappointing. With a 50 per cent failure rate, and with the possibility of toxic reactions always lurking in the background, we have thought that other methods of treatment would be preferable. Although the newer refinements of these agents cause extremely few toxic reactions, agranulocytosis and other serious manifestations are still enough of a possibility to make us more than a little alert. The extreme difficulty of the accurate, periodic and prolonged observation essential for patients receiving these agents, coupled with the great disappointment that the patient experiences when he is finally told that he will have to undergo some other treatment, is enough to direct us into other fields. At this time, we reserve the goitrogens, most commonly in the form of

propylthiouracil, for that small segment of the toxic patients, perhaps 10 to 12 per cent, who are not able to be prepared completely for surgical treatment with iodides alone.

Use of radioiodine is an apparently satisfactory method of treating many of these patients, especially those who have exophthalmic goiter. In fact, it is now routine treatment in many medical centers. It is a comparatively simple technique, although the patient may wonder why the person extending the medicament to him is wearing a lead apron and handing him the glass with metal tongs. The use of radioiodine is a relatively effective and long-lasting treatment in the great majority of cases. However, we have noted occasional recurrence of hyperthyroidism, occasional complete failure of the radioactive element, and a relatively large incidence of myxedema. Surgeons are called on occasionally to carry out radical subtotal thyroidectomy after the patient has had repeated courses of therapeutic radioiodine. Although the basal metabolic rate may have decreased temporarily, and other signs may appear to be favorable, the original situation appears to be redeveloping, so that finally surgical treatment has been the last resort. A few specimens in the tissue files at the clinic represent goiters of this type, which present homogeneous, nondescript, bizarre-looking tissue that certainly would not arouse much suspicion with regard to the possibility of continuing hyperthyroidism. These changes have been wrought by the repeated doses of radioiodine and yet the hyperthyroidism has recurred.

At the present time, we are alert, perhaps overly so, to the dangers of radioactive elements in these therapeutic doses. Since we know what happens to the thyroid gland, we have been concerned about what might be happening to the pituitary, the pancreas, the ovaries, the testes and other endocrine glands. Concern is felt about the ultimate development of malignant tumors in some of these organs, especially the thyroid. Although proved cases of cancer in the human as yet have not been ascribed to such an origin, malignant tumors have been produced experimentally in animals by this method. Everyone is aware that indiscriminate use of roentgen rays in the earlier days of such therapy produced carcinoma of the skin in many persons. We are now alarmed at the frequency of reports of thyroidal carcinoma in persons who received roentgen therapy during childhood because of "status thymicolymphaticus" or who were given radiation for recurrent adenoid and tonsillar disturbances. The great difficulty, of course, is the fact that several generations may have come and gone before the ultimate damage is apparent. Therefore, my associates and I are reserving the use of radioiodine for exophthalmic goiter in older patients, especially those beyond the menopausal years and certainly those beyond the active childbearing years. We also use it in younger patients who are poor surgical risks or in those patients with previous thyroidectomies in whom the technical hazards of yet another thyroidectomy might well predominate, such as a paralyzed vocal cord or permanent tetany. Even though the patient is youthful, it is easy to convince a surgeon that some means other than surgery should be employed if the patient has had a series of thyroidectomies without control of hyperthyroidism.

Our Present Stand in Exophthalmic Goiter

It already was indicated that the factor of mortality rate would have an effect on our reasoning in selecting present-day treatment. Up until 1945, our surgical mortality rate was averaging 0.5 per cent, which was thought to be the irreducible minimum. However, from 1945 through 1957, not a single surgical death occurred in a consecutive series of 1,742 thyroidectomies for exophthalmic goiter. This is considered to be an extremely significant figure.

With only a 5 per cent postoperative recurrence rate, with the quick control of the hyperthyroidism that usually occurs in the early postoperative days, and with such apparently permanent control, we still are of the opinion that the interests of younger patients exhibiting their first bout of hyperthyroidism of this variety are best served by carrying out radical subtotal thyroidectomy. Approximately 90 per cent of these patients can be placed in a satisfactory category with regard to surgical risk after 10 to 14 days of treatment with Lugol's solution alone. For the remainder, who are thought to be nonsuitable risks on such a program, a more prolonged period (perhaps 6 weeks) of treatment with propylthiouracil precedes the surgical treatment.

Adenomatous Goiter With Hyperthyroidism

We are now more convinced than ever before that this type of goiter should be removed surgically. The possibility of carcinoma of the thyroid is no longer controversial; the only argument is the exact incidence of such development. The presence of hyperthyroidism is no guarantee of immunity

against the development of malignant tumors, although we have found that fewer people with toxic adenomatous goiter also have thyroidal carcinoma. Subtotal thyroidectomy in these patients is extremely gratifying to the surgeon. The toxicity is overcome in a matter of days, and the recurrence rate of a true toxic adenomatous goiter is only 0.5 per cent. At the same time, one must be constantly mindful that there is a higher mortality rate among these patients. One is dealing with a much older age group, and the patients exhibit many more of the ills to which the aging body falls heir. The most prominent factor to be overcome is severe cardiac damage; unfortunately, this development is usually insidious, so that the patient may be brought to the hospital with a tremendously enlarged heart, gross irregularity of the pulse, and extreme hydrothorax, ascites and anasarca, thus presenting an obviously serious situation. It is no comfort to the surgeon to find that an adenomatous goiter has been present for many years and has been dismissed much too lightly. Unfortunately, Lugol's solution, the goitrogenic drugs, radioiodine and any other known medicament, while possibly effective to a certain degree, are much less efficient in this type of goiter. Sometimes we use all, or a combination of many, of these agents and still are much concerned about the ability of the patient to survive. By far the best plan is to treat the patient as vigorously as possible, to correct the cardiac decompensation and to check the extremely toxic state, if only momentarily, so that operation then may be done with reduced risk to the patient.

In 1945, again it was thought that an irreducible minimum had been attained, as the hospital mortality rate following subtotal thyroidectomy in this group of patients was 1.1 per cent. However, from that time up through 1957, only seven deaths occurred in a series of 1,252 consecutive thyroidectomies, giving a mortality rate of 0.5 per cent. Six of these seven deaths were the result of frank cardiac failure. The patients were known to be desperate risks. All possible methods of preparation were employed, and surgical treatment finally was undertaken as a last resort. The seventh patient had a thyroid "crisis," or "storm," which is an extremely rare phenomenon at the present time. This patient had not been considered to be in as desperate condition as were the other six, and she had been prepared by the administration of Lugol's solution alone. Cardiac decompensation was absent, and there was no warning of an impending crisis. However, she died on the third postoperative day in thyroid crisis, despite use of all known supportive measures.

Prophylactic Thyroidectomy

As already indicated, we have done 2,994 consecutive thyroidectomies in the surgical treatment of both types of toxic goiter (exophthalmic and adenomatous) from 1946 through 1957. Seven deaths occurred in this entire group, all in patients with adenomatous goiter, giving an over-all hospital mortality rate of 0.2 per cent. This might be looked on as a highly satisfactory state of affairs, possibly as the ultimate in the irreducible minimum. However, during that same period, we did 6,150 consecutive subtotal thyroidectomies for simple, nontoxic, adenomatous goiter with three deaths, or a hospital mortality rate of 0.05 per cent. It appears obvious that here is a tremendous field for prophylactic surgical endeavor. My associates and I encounter carcinoma of the thyroid in approximately 10 per cent of all single nodules that are treated surgically, and the rate is approximately 5 per cent in the multinodular gland. Even though carcinoma never entered the question, the possibility of toxicity developing late in life and progressing to an alarming state before it is recognized leads us to be most specific in urging patients to have the apparently simple goiter removed, as a much more nearly ideal set of circumstances will prevail if treatment is undertaken before the toxic changes are apparent.

Conclusions

Although modern nonsurgical methods are effective in treating hyperthyroidism, a definite place remains for subtotal thyroidectomy.

The present-day extremely low morbidity and mortality rates for thyroidectomy have reached almost the logical end point. The proper preparation and selection of patients have been responsible for this.

The use of goitrogens as definitive therapy has been disappointing to many physicians and surgeons.

Use of radioiodine appears to be a rather simple, frequently effective and usually lasting therapy, especially for exophthalmic goiter. It may prove some day to be the method of choice but, at the present time, the still unknown factors concerning it have deterred us from its universal employment.

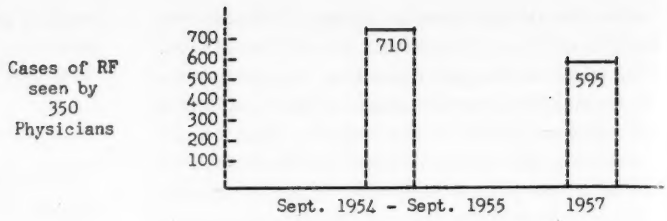

Fig. 1.

Rheumatic Fever Survey, 1958

WAYNE E. MATHY, M.D.
Heart Disease Control Program
Minnesota Department of Health
Minneapolis, Minnesota

IN 1955, the Minnesota State Medical Association, Minnesota Department of Health, and the Minnesota Heart Association[1] participated in a statewide rheumatic fever survey. The results of the 1955 survey and the subsequent follow-up study[2] showed that nearly 3,000 cases of acute rheumatic fever were diagnosed by Minnesota physicians from September, 1954 to September, 1955.

The 1955 survey provided an excellent baseline for further study of this disease and the effect of current therapy on its incidence and pathogenesis. With this in mind, the Minnesota State Medical Association sent rheumatic fever questionnaires to all Minnesota physicians in June, 1958. The questionnaire dealt primarily with the 1957 incidence of primary and recurrent acute rheumatic fever and the methods of prophylaxis being used. The Heart Disease Control Program of the Minnesota Department of Health compiled and analyzed the data received in this survey.

On June 10, 1958, 3,100 questionnaires and cover letters were sent to Minnesota physicians. Of these, 1,361 questionnaires were returned (44 per cent). However, several of the questionnaires included the experiences of more than one doctor

in a clinic practice. An analysis of the reporting physicians by type of practice, in the 1955 and 1958 survey, is shown in Table I.

The above distribution of reporting physicians in 1958 corresponds very closely to the physicians in the 1955 survey.

Analysis of Rheumatic Fever Questionnaire

Question 1: How many cases of acute rheumatic fever have you diagnosed during 1957?

A. First Attacks..... 977

B. Recurrent Attacks..... 575

Of the 1,361 doctors reporting, 466 saw a total of 1,552 cases of acute rheumatic fever in 1957 for an average of 3.3 cases per year. In the 1955 survey, 597 doctors saw a total of 2,297 cases for an average of 3.8 cases per year.[1]

In order to identify more accurately any change in rheumatic fever incidence from 1954-1957, data were obtained from 350 general practitioners, pediatricians, and internists, who participated in both the 1955 and the 1958 surveys.

The same 350 physicians saw 115 (16.2 per cent) fewer cases of acute rheumatic fever in 1957 than in 1954-1955. The proportion of physicians by type of practice was the same in this sample of physicians as in the total reporting physicians.

Table II shows that physicians reporting cases in 1957 saw 14 per cent fewer cases than in 1954-1955. This agrees very closely with the 16 per cent reduction of cases seen in the practices of 350 physicians who reported cases in both surveys.

We must be cautious in the interpretation of this 14 to 16 per cent reduction in cases. Statistically, this decrease in reported cases is not significant. A reduction of this amount might be explained on the basis of actual decrease in incidence of the disease or by the adoption of more rigid criteria for the diagnosis of acute rheumatic fever.

Recurrent cases of rheumatic fever made up 37 per cent of the total reported cases for 1957. The age of the patient when he has his initial attack of rheumatic fever is a very important factor in determining his susceptibility to recurrences. If prophylaxis is not given, children who develop their primary attack under ten years of age have a recurrence rate of more than 75 per cent.[3] This recurrence rate drops progressively if the primary attack occurs in children over the age of ten years.

The 575 reported cases of recurrent rheumatic fever represents the experiences of about one-half of the physicians in the state who diagnose and treat this disease. We can then assume that the actual number of recurrences through the entire state was considerably more than 575. This means that the majority of these patients were not following a proper prophylaxis routine for one reason or another. We know that 85 to 90 per cent of recurrences can be prevented if a continuous prophylaxis regimen is faithfully followed.[4]

Question 2: How many of the cases of recurrent acute rheumatic fever in Question 1B required hospitalization?

A total of 264 (46 per cent) of the cases of re-

TABLE I. REPORTING PHYSICIANS 1958 AND 1955

Type of Practice	Number of Physicians Reporting		Percentage of Physicians Reporting	
	1955	1958	1955	1958

*September 1954-September 1955.

current rheumatic fever reported in the survey required hospitalization.

Recurrent rheumatic fever is not only costly to the patient in terms of producing chronic cardiac disability and decreasing life expectancy, but also in terms of dollars and cents. The 264 patients who were hospitalized for acute recurrent rheumatic fever represent those patients seen by only one-half of the physicians in the state. The actual number of hospitalized cases in the entire state probably is nearer 500.

The average stay in the hospital for a case of acute rheumatic fever is two weeks, and the cost per hospitalization about $325.00. These figures are based on a study of 500 hospitalizations for acute rheumatic fever during 1957 and 1958. This means that approximately $175,000.00 was spent in 1957 for medical expenses and hospitalization resulting from acute recurrent rheumatic fever. This, however, is only a down payment. With each recurrence, particularly if valvular disease is established, the likelihood of further cardiac damage increases. These patients in later years often require many hospitalizations for bouts of cardiac failure and for the many complications of chronic rheumatic heart disease.

Question 3: (A) What method(s) of prophylaxis are you using on the patients mentioned in Question 1 to prevent recurrent attacks of acute rheumatic fever? (Please list *number* of patients and *length* of time you plan to keep these patients on each method of prophylaxis.) Refer to Table III.

Length of time patients are being kept on prophylaxis by method of prophylaxis: Refer to Table IV.

Some of the reporting physicians included patients who had attacks of acute rheumatic fever prior to 1957 in the question on prophylaxis. However, the vast majority of physicians gave prophylaxis data just on cases occurring in 1957: 80.6 per cent of patients receiving prophylaxis are getting medications at regular intervals for varying lengths of time; 14.7 per cent of patients on prophylaxis are getting drugs at intermittent intervals, particularly in the winter and spring months; about 5 per cent of the patients who developed acute rheumatic fever in 1957 are not on any prophylactic regimen.

The methods of prophylaxis used on patients diagnosed as having acute rheumatic fever in 1957 should reflect the philosophy of the physician toward prophylaxis. Therefore, with some exceptions, he probably uses similar method(s) of prophylaxis on all his patients who have had rheumatic fever prior to 1957. We thus should be able to show whether a relationship exists between the various methods of prophylaxis and the recurrence rate. At most, we can only hope to show a general trend between the above variables.

The over-all number of recurrences among the total 1,552 reported cases of acute rheumatic fever was 575 (37 per cent). Figure 2 includes comparisons between method of prophylaxis and recurrences only in those instances when the physicians reported a definite number of recurrent cases, a definite number of identifiable patients on prophylaxis, and a stated length of time these patients will be on prophylaxis.

TABLE III.

Method of Prophylaxis	Number of Patients	Length of Time You Plan to Keep Patients on Each Method of Prophylaxis
Continuous Prophylaxis	1,424	Please see table below
Intermittent Prophylaxis	260	
None	82	

TABLE IV.

Length of Time Patients are to be on Prophylaxis	Method of Prophylaxis			
	Continuous Prophylaxis		Intermittent Prophylaxis	
	Number of Physicians	Number of Cases	Number of Physicians	Number of Cases
Under 1 year	45	135	34	70
1-5 years	137	399	29	53
6-10 years	16	82	3	9
Indefinitely	110	493	13	44
Until 14-18 years of age	33	129	1	1
Until over 18 years of age	33	119	4	12
Indefinite	18	67	10	26
PRN	—	—	14	45
Totals	392	1,424	108	260

PROPOSED LENGTH OF TIME ON PROPHYLAXIS

It must be remembered that there is a marked difference in numbers of cases when these three methods of prophylaxis are compared. Eighty per cent of the patients are on continuous prophylaxis for various periods of time. When continuous prophylaxis is analyzed, it is seen that physicians who use long periods of prophylaxis (five years or longer) reported fewer recurrent cases among their total cases for 1957. Possibly physicians who prescribe long-term prophylaxis have better patient co-operation, with fewer lapses in therapy and consequently fewer chances for recurrences to occur.

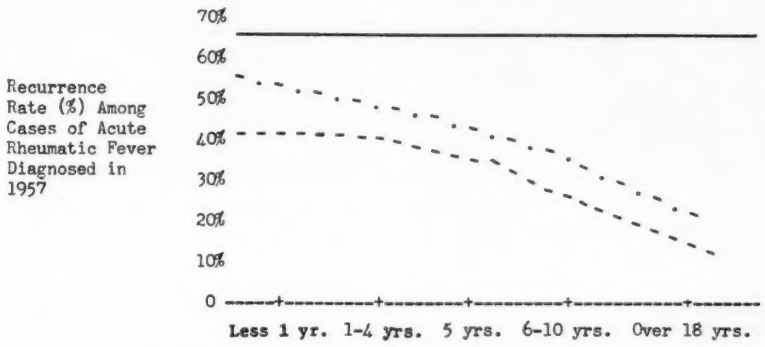

Fig. 2. (– –) *Continuous Prophylaxis:* 231 doctors—695 cases; 247 recurrences (35.5 per cent). (–•–) *Intermittent Prophylaxis:* 62 doctors—153 cases; 74 recurrences (48.3 per cent). (—) *No Prophylaxis:* 16 doctors—31 cases; 20 recurrences (64 per cent).

Question 3 (B) What type of prophylactic medication are you giving patients who have had acute rheumatic fever? (Please check medication (s) you are using.)

1. Oral Penicillin..... 443
2. Injectable Penicillin..... 270
3. Sulfa 155

The majority of reporting physicians who treat this disease checked oral penicillin as the drug used in the prevention of recurrent rheumatic fever.

The problems of treatment and prevention of rheumatic fever are difficult ones. In many cases, the diagnosis is in doubt because the presenting symptoms may be non-specific. When the diagnosis is difficult to make, the decision on long-term prophylaxis presents an even greater problem. Patients often feel entirely normal between attacks of rheumatic fever. For this reason, it is hard for a family or patient to realize he needs medication for a long period of time, possibly for life.

We do know that the prompt treatment of streptococcal infections and the use of recommended prophylactic regimes will prevent 85 to 90 per cent of acute rheumatic fever. The American Heart Association recommends the following routine in rheumatic fever prevention. (Taken from the second revision of the American Heart Association statement on prevention of rheumatic fever. Published in *Circulation,* Volume 15, 1957)

PREVENTION OF PRIMARY RHEUMATIC FEVER

Treatment of Streptococcal Infections

1. Intramuscular penicillin-Benzathine penicillin G
   Children: One intramuscular injection of 600,000 to 900,000 units.
   Adults: One intramuscular injection of 900,000 to 1,200,000 units.
2. Intramuscular penicillin-Procaine penicillin with aluminum monostearate in oil.
   Children: One intramuscular injection of 300,000 units Q 3 days for 3 times.
   Adults: One intramuscular injection of 600,000 Q 3 days for 3X
3. Oral penicillin
   Children and Adults: 200,000 to 250,000 units TID for 10 days
4. Broad Spectrum antibiotics
   Children and Adults: Therapeutic doses for 10 days.

PREVENTION OF RECURRENT RHEUMATIC FEVER

Prevention of Streptococcal Infections

1. Intramuscular penicillin-Benzathine penicillin G
   Children and Adults: 1,200,000 units per month
2. Oral penicillin
   Children and Adults: 200,000 to 250,000 units Q day or BID. The latter is preferred.
3. Oral sulfadiazine
   Children and Adults: 0.5 to 1.0 grams per day. The smaller dosage is for children under 60 pounds.

Streptococcal infections can occur at any age and recurrences of rheumatic fever have been reported in the older age groups. The American Heart Association therefore recommends that the safest general procedure is to continue prophylaxis indefinitely.

Question 4: (A) How many clinically inactive rheumatic fever patients do you have who you believe should be on continuous prophylaxis, but who are not, for some reason? (Please list *number* of such patients on the right.)

(A) 1,059

(B) How many of these patients are not on continuous prophylaxis because of the following reasons? (Please list *number* of such patients on the right.)

(B)

1. Lack of interest on the part of the parent or patient 625
2. Reaction to the drug(s)..... 26
3. Cost of prophylactic drugs(s)..... 262
4. Other not stated..... 146

At least 1,059 patients are not on continuous prophylaxis although such a regimen was prescribed by their physicians. Two-thirds of these patients are not on the prescribed medication because of their lack of interest and one-fourth because of the cost of the prophylactic drugs. Only 2.4 per cent of the patients were not able to take medications because of drug reactions.

Summary

The survey shows quite definitely that rheumatic fever is still a problem in Minnesota. Although the average number of cases seen by physicians in 1957 was 15 per cent below the 1954-55 average, we cannot say this was entirely due to an actual decrease in the incidence of the disease. If the degree of over-reporting was the same as the 1954-55 study, a conservative estimate would be that 2,400 cases of acute rheumatic fever were diagnosed and treated by Minnesota physicians in 1957.

It is also evident that methods and length of prophylaxis vary a great deal throughout the State. Several factors account for the many different prophylaxis routines, some of which have been mentioned in the discussion of the survey question. Past experience with the disease guides physicians as to the method of prophylaxis they use.

The large number of patients who are not on a continual prophylaxis program, although it has been prescribed, brings out the need for an active patient and parent educational program. If untreated, it is expected that 10 per cent of these patients will have a recurrence within one year. The most successful education of these patients and parents can be done directly by physicians.

Of the total cases of reported acute rheumatic fever in 1957, 37 per cent were recurrences. Of the estimated 1,000 recurrent cases in 1957, 90 per cent could have been prevented by means of a secondary prophylaxis program at a cost of approximately $20,000.00. These same 1,000 recurrences cost $175,000.00 alone in hospitalization and medical expenses, plus the immeasurable cost to the patient in terms of increased valvular damage which may occur with each recurrence.

We thus have evidence that there is not only a need for an active educational program in combatting rheumatic fever, but also for an adequate secondary prevention program. These programs can be achieved only through the co-operation and participation of the medical profession, voluntary agencies, and the official agencies who are concerned with the prevention of this disease.

Some basic questions which must be considered during the development of a rheumatic fever prevention program are:

1. What can be done to promote patient and parent acceptance of recommended prophylaxis against rheumatic fever?
2. What part should the official and voluntary agencies play in promoting a secondary rheumatic fever prevention program?
3. What is the best means of getting participation of the practicing physicians in a secondary prevention program?
4. Who should take the administrative responsibility for developing the mechanics and operating a prevention program?
5. What type of secondary prevention program would be best suited to Minnesota in terms of: (a) case finding and registry; (b) provision, dispensing, and cost of drugs; (c) follow-up?

Toxoplasmosis in a Newborn Infant

Case Presentation

CHARLES G. SHEPPARD, M.D.
Hutchinson, Minnesota

Fatal toxoplasmosis in a newborn infant is rare. A beautifully documented case report is recorded. The over-all problem of toxoplasmosis in pregnant women and in newborn infants is reviewed.

Case Presentation

BABY B. A. was born December 26, 1958. During mid-January, 1949, he developed difficulty with feeding and unexplained fever. This did not respond to the usual medications available. On January 27, 1949, he was sent to the University Hospital for diagnosis and treatment. On admission to that hospital, the baby appeared to be rather acutely ill with some generalized hyperactivity of reflexes and a marked tremor of his arms, especially on the right. A spinal puncture was done which revealed an increase of total cell count and a protein of 355 mg. per cent. There was a slight amount of blood elicited with this tap so its accuracy was not certain, but a repeat tap showed a total of 76 cells with a protein of 768, and sugar of 28 mg. per cent.

The patient was started on sulfadiazine as well as streptomycin and penicillin. He had a leukocytosis on admission of 20,850 cells per cu. mm., with N32, L60, and E8. The second count revealed 22 per cent eosinophils. This suggested toxoplasmosis. Routine skull x-ray (Fig. 1) revealed diffuse calcification consistent with the diagnosis of toxoplasmosis. Streptomycin and penicillin were discontinued at this time. A ventriculogram was performed which revealed a marked internal hydrocephalus. The Sabin-Feldman dye test for toxoplasmosis was positive in serum diluted 1:512. The child was continued on sulfadiazine in fairly large doses. At that time it appeared that the drug was effective against toxoplasmosis. The baby continued to take sulfadiazine, and was discharged to his family physician with a poor prognosis. The dye test for toxoplasmosis on the mother was found to be positive in serum diluted 1:512 and the father was negative.

The patient was re-admitted to the University Hospital on April 20, 1949, and discharged on May 21, 1949. He died on May 22, 1949. While he was in the University Hospital on the second admission he had a lamina terminalis puncture. There were numerous adhesions around the right choroid plexus. These were broken up. The lamina terminalis was visualized and a hole about 1 cm. in diameter was made. This tissue was examined

and found that it contained very many gemistocytic astrocytes, probably indicative of toxoplasmosis activity.

Initially, the child did quite well, but by the fifth postoperative day he developed spasticity and vomiting. Ventricular taps were done as needed. The outlook seemed very poor because of the activity of toxoplasmosis, and, in all probability, the ventriculostomy became occluded because of proliferation of infected tissue. The prognosis was poor from the beginning.

A postmortem examination was refused, but a positive diagnosis of toxoplasmosis could nevertheless be made in this case.

The Problem

Because of the unusual nature of this disease, certain questions were asked and the author found that few answers were known. One of the questions that arose at the time was: How had the infant acquired the disease? It was found that it was most likely a congenitally-transmitted disease in this case. There was no particular reason to suspect anything like it, because the mother has been perfectly healthy during her pregnancy and had no symptoms indicating the presence of any acute disease. Here was a situation where an apparently perfectly healthy young woman had a disease which did not produce any recognizable symptoms during her pregnancy and yet was severe enough to be passed on to her child and cause his death after delivery. Inasmuch as the answers to some of the questions were not obtainable at the time, it was decided to investigate further this situation in obstetrical patients. A considerable amount of correspondence was had with the University Hospital staff members and, in particular, with Dr. Richard Smith. He was very helpful in the discussions concerning this disease.

Discussion

In order to find out more about this disease, it was necessary to enlist the aid of the laboratory section of the State Board of Health.

From 1949 to 1954, one or more blood samples from 327 obstetrical patients was sent in to the State Board of Health Laboratories. Because of this initial sampling, a number of corollary studies have been done and have been reported elsewhere,[1,2] and some questions have come to mind, the answers to which might be of interest to all physicians who have an obstetrical practice.

1. How is the disease transmitted or acquired after birth? This is not known.[3] It is presumed to be transmitted from animals to man but whether it is inhaled, ingested, or inoculated by an insect vector is not known.

2. How widespread is the disease in the general population of Minnesota? If we consider the dye test to be absolutely specific and there is no evidence that it is not specific in humans, then about 1 per cent of the population of Minnesota acquires toxoplasmosis each year.[1]

Therefore, about 10 per cent of ten-year-old children have had toxoplasmosis; about 20 per cent of twenty-year-olds, and so forth.

3. Is the disease more prevalent in males or females? All studies show no significant sex difference in the acquisition of toxoplasmosis.[4]

4. What age group does it affect most or are all age groups susceptible? All age groups are susceptible.[4]

5. Does immunity develop without evidence of the disease? Yes. Infection (and the resulting immunity) without clinical illness is usual when the infection is acquired after birth. A good example of this is found with the mothers of the infants in the congenital cases. The State Board of Health has accepted thirty-six as congenital cases from January 1949 to date. (Twenty-nine of the thirty-six were Minnesota residents). Only one of the thirty-six mothers reported a febrile illness during pregnancy.

6. What are the primary symptoms of the disease in humans? Congenitally-acquired toxoplasmosis during the neonatal period shows signs of encephalitis, rash, jaundice and hepatosplenomegaly. The appearance and clinical course may suggest erythroblastosis. Hydrocephaly, microcephaly or chorioretinitis may also be present. The child may be born dead showing these manifestations. Should the child survive during infancy and childhood, there may be hydrocephaly, microcephaly, convulsions and/or psychomotor retardation in conjunction with chorioretinopathy. Chorioretinopathy is considered essential to the establishment of a firm diagnosis in this group of cases. The other conditions above may be due to a number of different causes. Cerebral calcification is common but not universal.[5]

Postnatal acquired toxoplasmosis may have a wide spectrum of manifestations of illness. Most infections are inapparent, as is evidenced by the number of persons with positive dye tests whose histories do not suggest any particular illness that could be construed as having been the responsible

infection, nor do these persons have any physical findings that would suggest past infection. It is rare for mothers who transmit the disease to their offspring to be able to describe any suspicious illness during the course of pregnancy. It is reasonable to suppose that some types of cases so far described in proven acquired toxoplasmosis are those with generalized lymphadenopathy,[6] and those with a rash of Rickettsial character.[7] The problem of the frequency of the connection between chorioretinitis in adults and acquired toxoplasmosis has not yet been settled.[8] In this connection, it is well to remember that chorioretinitis in children may make a delayed appearance. It has been the practice of the State Board of Health arbitrarily to put the age of twelve years as the dividing point as to the time when a chorioretinitis may have been the result of a congenital infection, and the time when it is probable that the chorioretinitis was acquired (whether due to toxoplasmosis or not).

Acquired toxoplasmosis, whether of the glandular or exanthematous type, is of course a febrile disease. The first symptom of chorioretinitis is blurred vision. Ophthalmoscopic examination is necessary to define the character of the lesion.

7. What are the pathologic conditions to be recognized or to be watched for in making a diagnosis? This has been to some extent answered in the above discussion. None of these symptoms or signs, alone or in combination, is absolutely diagnostic. Specific diagnosis can be accomplished by isolation of *Toxoplasma gondii* or by serologic methods properly interpreted. The commonest conditions for which toxoplasma tests are requested are psychomotor retardation, convulsive states, and chorioretinitis. In congenital toxoplasmosis, the tetrad of chorioretinitis—cerebral calcification, hydrocephaly or microcephaly, and psychomotor retardation—is most often attended by serologic confirmation. Requests for toxoplasmosis studies should always be just one part of a general and complete work-up. Overt toxoplasmosis is still too unusual a clinical entity to have a diagnostic priority in the mind of the physician. This attitude should apply to the acquired glandular and exanthematous forms also.

8. What serological results on the mother indicate no need to expect congenital transmission? (a) If the mother is not infected, the dye test is negative during pregnancy and also at delivery. (b) If the mother has an old infection, the dye test is positive and the complement fixation tests negative on the mother's blood both during pregnancy and at the time of delivery. A positive dye test and negative complement fixation test during the pregnancy only, would usually mean an old infection, but in rare instances would indicate a recent infection. A test of the mother's blood at the time of delivery should be made to look for a rise in titer in the dye test and in a change from negative to positive complement fixation tests to exclude this rare possibility.

9. What serologic results on the mother indicate the possibility of congenital transmission? (a) A mother with recent infection or infection during pregnancy would show a negative dye test during pregnancy and show a positive dye test at the time of delivery. (b) If her dye test was positive and her complement fixation test negative during pregnancy with the complement fixation tests changing to positive at the time of delivery. (c) If her dye test was positive (1:256 or higher) and the complement fixation tests positive in dilution 1:8 or higher, both during pregnancy and at the time of delivery. This type of reaction could be expected in about 1 to 2 per cent of pregnant women. The types of reactions showing an increase in positivity during the pregnancy could be expected in less than 1 per cent of obstetrical patients.

10. What serological results on the infant confirm suspected congenital transmission? The dye test titer in the infant must be as high or higher than that in the mother and be maintained at that titer past the age of three months. The complement fixation tests may be positive or negative at birth; if negative, the complement fixation will change to positive in dilution 1:8 or higher within three months or earlier.[9] Dye test titers lower than 1:256 have not been observed in patients with congenital toxoplasmosis nor in the mothers or the patients when the testing is done within the first year of the infant's life. Usually the dye test titers on patients are positive in dilution 1:1024, 1:4096 or occasionally higher.

11. How many years may go by in any given case before any danger from the effect of the congenital disease may be considered past? The answer to this question is not known. It is possible, but not proven, that chorioretinitis in adults may be a late manifestation of the congenitally transmitted disease.

12. Do obstetric patients infect the offspring of more than one pregnancy? No, or at least none have been reported in the literature. This suggests that the length of time after acquiring the infection in which it can be transmitted to the fetus, is relatively short.

13. Is the disease prevalent enough in the general population, particularly in obstetric patients, to warrant checking all pregnant women, cord bloods at birth, and follow the titers of babies following delivery? The prevalence of this disease in terms of the actual potential of congenital transmission is not known. Based on the 327 patients in the author's series and the 272 who were followed, it can be said that less than 3 per cent have serological results indicating that transmission is possible.[1] How often congenital transmission occurs in this 3 per cent is unknown, but prevalence is not the crux of this question. If the 80,000 obstetric patients in Minnesota were tested each year and 2,000 of them with serologic results indicating that a transmission of toxoplasmosis was a possibility, treatment could not be recommended for these 2,000 women on the basis of the unknown risk to the child. Few of these 2,000 women would transmit the disease to their offspring even if untreated. Also, treatment of these 2,000 pregnant women could not be recommended because the drugs are moderately toxic and their treatment value is not well established.

One must also mention cost. These tests are markedly more expensive than tests for syphilis. Therefore, an extensive case-finding program would be prohibitive in cost, inasmuch as multiple tests are necessary on each patient. The expenditure of funds is better directed toward learning how the disease is transmitted so that pregnant women can be advised how to avoid the risk. Basic research for better therapeutic agents is also a real need and this is being carried on in several places.

14. What is the treatment for acute toxoplasmosis, if any? Pyrimethamine (an antimalarial drug) combined with one of the sulfa drugs is recommended.[10] These have had only limited trial and should be used with caution. Pyrimethamine is moderately toxic.

Conclusion

The routine examination of the blood of all obstetric patients with specific reference to the finding of toxoplasmosis titers would be unwarranted. If there are other conditions and symptoms suggesting that such a blood study might be utilized, only then could such tests be recommended. Sabin has stated the situation very well: "It may well be that all future studies will show that in toxoplasmosis we have an example of that almost perfect host-parasite relationship in which the parasite only rarely causes serious damage to its hosts and the hosts are not too intent on destroying the parasite—in other words a great deal of infection and very little disease."[11]

Acknowledgments

The author wishes to acknowledge his great indebtedness to the people at the Minnesota State Board of Health in helping to carry out this work and to prepare this paper. These include especially Dr. Anne C. Kimball, who is preparing a number of other papers on this subject, Dr. Henry Bauer, head of the laboratory section and Dr. Herman Kleinman, head of the chronic diseases department. Without their generous assistance the writing of this paper would not have been possible.

ANTIHYPERTENSIVE AGENTS

I. The Role of Diuretics

The advent of potent oral diuretics such as chlorothiazide (diuril) and its analogue hydrochlorothiazide (esidrix; hydrodiuril) promises to revolutionize the treatment of hypertension. These agents have a modest hypotensive action when administered alone, and they are even more effective in enhancing the hypotensive response to ganglion-blocking agents and hydralazine (apresoline). To a lesser extent, they augment the antihypertensive action of compounds of Rauwolfia and Veratrum.

The mechanism by which chlorothiazide and hydrochlorothiazide reduce blood pressure has not been definitely elucidated. Long-term administration of chlorothiazide leads to a decrease in the volume of extracellular fluid and plasma, even in nonedematous patients. Cardiac output is also reduced, possibly as a result of this. Whether this nonspecific effect of diuresis is the modus operandi or whether there is a more specific and esoteric hypotensive action is a matter of dispute.

Unlike other hypotensive agents, chlorothiazide produces extremely few unpleasant side effects and is consequently well tolerated by most patients. Only rarely do gastrointestinal symptoms such as nausea, vomiting, abdominal distress and diarrhea force cessation of therapy. Some patients complain of a dry mouth or an unpleasant taste or both and some describe a vague weakness, but these symptoms seldom are intolerable, and they usually bear no relationship to the level of serum potassium.

Disturbances in blood electrolytes are the most frequent and potentially most serious side effects produced by long-term administration of chlorothiazide or hydrochlorothiazide. Hypopotassemia (serum potassium less than 3.5 mEq. per liter) occurs in approximately 40 per cent of patients at some time during therapy with chlorothiazide. Yet only rarely are clinical symptoms present to suggest potassium deficiency, and hence it will escape detection unless routine determinations of serum potassium are made. The administration of supplementary potassium is advisable if the value for serum potassium is low or if patients become acutely ill or require operation. In the latter instances, intake of potassium is sharply curtailed and losses are likely to be exaggerated; consequently, severe hypopotassemia may be precipitated rather abruptly if body stores of potassium already are partially depleted by prolonged administration of chlorothiazide. Supplementary potassium should be given routinely to patients who are taking digitalis in addition to chlorothiazide, since hypopotassemia aggravates digitalis intoxication.

Attempts to consume more foods rich in potassium, such as orange juice, usually do not suffice to prevent hypopotassemia, especially during acute illnesses. A preferable and more reliable method is the regular administration of tablets of potassium chloride or a solution of potassium triplex. It is not uncommon that supplements of potassium in the order of 90 mEq. per day (approximately 7 gm. of potassium chloride or 24 ml. of potassium triplex) will be required to prevent hypopotassemia in patients taking 1 gm. of chlorothiazide daily. In stressful situations, when losses are exaggerated, more than this amount may be necessary. The physician must not allow himself to be lulled into a false sense of security by administration of supplementary potassium, for this is not a guarantee against hypopotassemia.

Like serum potassium, the blood urea (or nonprotein nitrogen) should be determined at regular intervals when patients are receiving chlorothiazide, since an increase in blood urea occurs in about 20 per cent of hypertensives who have normal pretreatment values. The value for urea usually returns to normal despite continued therapy. When it does not, forcing fluids or reducing the dose of chlorothiazide is sometimes effective in correcting this abnormality. In some cases, the urea remains persistently increased at levels of 50 to 60 mg. per 100 ml. (normal is 40 mg. or less) as long as chlorothiazide is administered. Evidence of progressive deterioration in renal function as the result of chronic administration of chlorothiazide has not been forthcoming, but persistent increases in blood urea are certainly a source of concern.

Pre-existing azotemia, even though of mild degree, is a signal for extra caution, because further and sometimes alarming increases in blood urea occur in nearly 50 per cent of such patients when chlorothiazide is administered.

When renal function is normal, chlorothiazide rarely produces abnormalities in serum sodium or in plasma chloride or carbon dioxide. Increase in uric acid sometimes occurs, and hyperglycemia has been attributed to administration of chlorothiazide.

Purpura, thrombocytopenia and anemia have resulted from treatment with chlorothiazide, but such instances are rare when one considers the large number of patients who have been treated with this drug.

So effective is chlorothiazide in enhancing ganglionic blockade that care must be exerted to prevent orthostatic collapse when this diuretic agent is added to the regimen of a patient taking a ganglion-blocking drug. In such instances, the dose of ganglion-blocking drugs should be reduced about 50 per cent in anticipation of adding chlorothiazide, and the latter should be administered in small doses (250 mg. twice daily or less) at first.

Orthostatic hypotension also can result from combination therapy with chlorothiazide and hydralazine.

If chlorothiazide and similar diuretic agents prove to be relatively free of toxic side effects when used for long periods, and if their administration is judiciously monitored by periodic determination of serum potassium and blood urea, this new class of antihypertensive drugs may well sound the death knell of Rauwolfia and herald a limited renaissance of surgical sympathectomy.

Experience has shown that Rauwolfia is a deceptive drug; the longer it is used, the less one respects its hypotensive properties and the more one fears its insidious and late side effects. Most dangerous among these are depression and a parkinsonianlike state, both of which may be so well disguised that they escape detection of patient, family and physician alike until serious disability results. Despite these objections, Rauwolfia has been used widely, although at times reluctantly, as a cornerstone on which to build a therapeutic regimen. For some patients, it suffices as the sole hypotensive agent; for those who need additional therapy, it tends to reduce the incidence and severity of unpleasant side effects produced by more potent agents. Until the advent of effective oral diuretics, there was no substitute for Rauwolfia in this role of advance guard in the attack on hypertension. Chlorothiazide and hydrochlorothiazide, however, are proving to be even more effective than Rauwolfia in reducing blood pressure, either alone or as adjuncts to therapy with hydralazine and ganglion-blocking drugs. Moreover, chlorothiazide rarely produces symptomatic side effects itself and, when used in combination, it usually permits better control of blood pressure with smaller doses of those antihypertensive drugs that do tend to cause unpleasant symptoms. It has been my impression that, like Rauwolfia, it also reduces the frequency and severity of tachycardia, palpitations and headache that often accompany the administration of hydralazine.

If continued experience bears out early observations that chlorothiazide is uniquely effective in reducing blood pressure after thoracolumbar sympathectomy, it is conceivable that a limited, one-stage procedure that would leave the male reproductive functions intact could, with the addition of chlorothiazide, be an extremely effective weapon in the management of hypertension. For selected patients, this type of combined surgical and medical approach might be accompanied by fewer side effects than would extensive surgical or intensive medical therapy alone.

The net result of the introduction of diuretic agents into the field of antihypertensive therapy is better control of hypertension with fewer unpleasant side effects from drugs. This should mean ultimately that more patients who have mild and asymptomatic hypertension will be able to take advantage of the protection that effective treatment almost certainly affords without sacrificing their comfort. The physician must realize, of course, that late toxic effects from chlorothiazide may yet appear, and this specter must temper his judgment as he balances the risks of untreated hypertension against the risks of therapy for each patient.

MEDICINE'S GREATEST PROBLEM

The most outstanding problem, as the twentieth century grows older, is that humanity through discovery of powerful scientific means is threatening radical change of human nature itself. The very basis of human existence, which had remained stable for thousands of years, appears to have been

upset and altered. Contentment has been outstripped by infinite desire for power and control over even space beyond. Science and myth are fast becoming one.

Man, through his restless creative drives, is producing ever-changing environment which needs adaptation at every turn. The acceleration of change of these new stresses, new efforts and new endeavors constitute a challenge to our organism and personality. Humanity must either meet the challenge satisfactorily or succumb to it. If the old idea that disease is the result of lack of harmony with nature is true, the rapid change in man's new environment is the great problem of the medical science tomorrow.

It comes to this, then, that the technocratic advance in this atomic age would create not only cosmic catastrophe but also newer problems in contemporary medicine concerning both biophysical and biological adaptation. Can human beings keep pace with this new change?

Humanity sooner or later would desire to be immortal or to have a longer life adequate for inter-planetary travel. Due to victory over infective diseases, the expectation of life has definitely become longer in the present century than it has ever been before. The degenerative process of wear and tear, however, continues relentlessly although at a slower pace. We are living longer but dying gradually; in other words, modern medical science in a large measure has "exchanged mortality for morbidity." This disparity between rate of cosmic and biological advancement is bound to create an impact leading to increase in stress syndrome and emotional crises, which would be the problem of problems with the advance of science.

If humanity fails to adjust itself to this pace of progress, the science of medicine will have to devise an effective check on these emotional crises. This, I believe, will give a new dimension to medical science to make it dynamic and anticipatory instead of episodic, as at present.

Thus, the main problem of medical science is to make man more capable of adjusting himself to his complexes and environment. The challenge of matter must be met by the mind of man, which may evolve a new art of life in answer to the challenge of the age.

DR. MD. ILBRAHIM

HYPNOSIS IN MEDICINE

Since the report of the Council on Mental Health of the AMA on hypnosis was published, there has been an increasing interest in hypnosis by the medical profession. This rather sudden and widespread interest is somewhat forboding to anyone who believes that hypnosis may serve a useful purpose in medicine and in other aspects of life. There is a natural tendency to fear that history may repeat itself, meaning that the present interest would fade away into a state of apathy to the potentialities of hypnosis.

The only compelling reason for history to repeat would be negated by putting hypnosis in its true perspective among the many techniques which the physician has to aid his patients. Every physician knows that patients often feel better simply as the result of a visit to his office and a talk with him. Physicians also know that medicine has a psychological value over and beyond the physiological changes produced by the drug. Every physician knows that the morale of the patient and the "will to live" often have an effect upon the prognosis of a disease. Physicians know that psychological etiology is outstanding in some types of disease and discomforts suffered by patients. In short, psychological factors are important in the causation, treatment, and course of disease.

How do these commonly known medical facts relate to hypnosis? It is simply this: Hypnosis is a powerful tool for manipulating psychological factors. Like any other instrument, drug or technique, sometimes it doesn't work at all; sometimes it doesn't work very well; and sometimes it works extremely well; and sometimes it cannot be used. As is characteristic at the moment of most psychological techniques, our predictability of how it will work in a given patient is not as good as it is for many of the physiological procedures and more mechanical techniques.

Psychologically, what is hypnosis? It is an attitude or mood of great receptivity to the words and actions of the hypnotist. To paraphrase a recent writer, Barbar, the process of going into hypnosis involves on the part of the patient these steps:

1. He becomes more and more concerned with words of the hypnotist and with those aspects of his self and his surroundings to which the hypnotist specifically directs the patient's attention.

2. He becomes more and more ready and willing to carry out the instructions of the hypnotist.

3. He comes gradually to believe that what the hypnotist says is the literal truth, and what the hypnotist says will happen is going to happen. In other words, the patient comes to think as the hypnotist wants him to think.

Now, surely, to the extent that these steps are effectively carried out by the patient, and to the extent that the physician knows how to direct the thoughts of the patient for the latter's benefit, it is obvious that this mood of receptivity, hypnosis, would give the physician greater control over the psychological factors underlying the patient's disease or discomfort.

However, only "good" hypnotic subjects can carry through all of these steps to the maximum degree, and even they do not become automatons to be pushed around at the will of the hypnotist. The most excellent hypnotic subject will go through the steps on a permissive basis, and should the hypnotist attempt to abuse this permissiveness, the subject can withdraw his permission. However, the medical man will usually be working within the permissive limits of the patient, except perhaps in some cases of deep psychotherapy where the therapist may run into material which the patient consciously or subconsciously wishes to keep hidden.

Paradoxically, perhaps, the greatest medical use of hypnosis will likely not lie in the field of deep psychotherapy, and most medical uses of hypnosis do not necessarily require that the patient be in deep hypnosis. Perhaps the most widespread medical use of hypnosis is that of relieving anxiety and tenseness. Look at steps 1 and 2 above! If the patient will concentrate his attention to the words of the hypnotist, that of itself will draw his attention away from what is causing anxiety and tenseness. Then as the patient carries out the instructions of the hypnotist, which are always in clinical hypnosis directions for relaxation, that relaxation will occur. Then with carefully chosen words and skillful psychological manipulation, the physician can begin to change some of the erroneous ideas of the patient and make beneficial substitutions. By this means, to give a few examples, the patient can be prepared for childbirth, given training preliminary to general anesthesia, and for postoperative comfort, relieved of anxiety and tension engendered by the anticipation and performance of many medical examinations. The patient may also be brought to a new philosophy of life which may result in the alleviation of some of the psychosomatic disorders.

There is evidence that in many patients the discomfort of burns may be alleviated, and some physicians believe the progress of healing is promoted. In some cases, the patient's discomfort in the terminal phase of incurable disease can be lessened.

This list of possible uses could extend endlessly, but a general restatement will have to suffice: Where psychological factors are an important factor in medicine, hypnosis is a technique which gives some possibility of control of these factors.

Looking at hypnosis as set forth above, it does not appear particularly esoteric, magical or unusual. It is simply carrying on in a more deliberate and perhaps effective manner what every physician seeks to do. It simply is using in a more formal way what the physician is already using. For example, the patient is already set to pay attention to what his physician says, otherwise he wouldn't come to the office. He is usually willing, at the moment, to carry out the physician's instructions, although his willingness may often disappear rather quickly after he leaves the office.

However, by the use of hypnosis the physician can increase the probabilities that the patient will behave as the physician tells him to. Of course, the probabilities will not reach 100 per cent. The use of hypnosis simply allows the physician to work with greater odds in his favor, and by the same token in favor of the patient. This is accomplished primarily by the use of posthypnotic suggestions; i.e., suggestions given in the hypnotic state but to be carried out after the hypnosis has been formally terminated.

But how does one get a person into the frame of mind in which he is more receptive and cooperative than he usually is? This brings us to the so-called "methods of hypnotic induction." These are strictly empirical procedures in the sense that we know they work but are not too certain about how or why they work. The various methods all use the same general principles, and are usually composed of simple muscular exercises together with talk on the part of the hypnotist. Any physician can learn these techniques, and they probably should be taught, together with the principles involved, to medical students as a regular part of their training. In addition, the student should

have a background of knowledge of human behavior and especially of its motivation.

Even if some of these students never used hypnosis formally in their practice, the study of it would impress upon them most vividly the principle that ideas are the most powerful instigators of the behavior with which they have to deal during every day of their practice. This, in a nutshell, is the secret of medical hypnosis: Implant an idea in the mind of the patient in such a way that the patient will not resist the idea, and the action indicated by the idea will almost inevitably occur.

WORKING WITH SPACE IN THE PROFESSIONAL OFFICE

An article in a late issue of a leading building trade publication talks about a "ripe, new market" for commercial buildings having a residential appearance . . . professional office buildings.

This development is undoubtedly due, in large part, to the move to the suburbs we hear so much about. While there will most certainly always be a need for downtown doctors' offices, a suburban location has much to offer: proximity to patients, ample parking facilities, quiet surroundings, lower building costs, and the possibility of renting out office and examining room space to other professionals.

In planning for a new, suburban type office of this nature, the architect or builder will require help in arranging the floor plan or layout that will be best suited to the individual doctor's needs. The location of heavier equipment, dressing rooms, reception areas, office space, heating equipment, all have important bearings on the layout, and on construction costs as well.

Typically, a long corridor will run the length of the building from the reception area to the back wall. Rooms serving the purposes outlined above are then economically arranged on either side of the corridor. The major drawback to this arrangement, oddly enough, is rarely disclosed until it is too late—door-swing space.

Obviously, doors cannot be permitted to open outward into the corridor without excessive hazard to people passing through. On the other hand, doors that open into the rooms effectively waste large areas of floor and wall space—forcing unsatisfactory furnishing arrangements inside the rooms, or necessitating larger rooms and consequently higher building and maintenance costs.

A simple way out of this quandary is the use of accordion folding interior doors. These doors fold open and closed entirely within the doorway, so that tables, chairs, equipment or cabinets can be located immediately on either side of them within the room itself.

* * *

Some of the more obvious methods of effectively utilizing available space are the use of built-ins, cabinets, and storage walls. For example, in little more area than normally used by a desk, a counter can be built to close off the receptionist's area. The counter can serve efficiently as both a desk and storage for all records, eliminating the need for separate filing cabinets . . . and usually at a lower cost than a desk and filing cabinets combined.

Built-in cabinets similar to those found in home kitchens are also efficient space-savers, and permit utilization of all the space along the floor and wall of a room—right up to the ceiling! Too often, a heavy-laden, free-standing cabinet (that looks like an old dresser painted white) is permitted to occupy a dominant position against an otherwise blank wall, while the doctor searches hopelessly for a place to store an extra "Band-Aid."

If there is need for an extra room every day, facilities are obviously just too inadequate for one's business. On the other hand, if the need arises only occasionally, and doesn't justify the cost of additional construction or moving to new quarters, there are other possible solutions.

Free-standing, folding screens can be used to good advantage where complete privacy—including both sound and sight—is unimportant. They are quite flexible in that they can be moved to any part of a room, or from one room to another, if necessary. Their flexibility, however, creates problems of handling, and of storage when not in use. In addition, they tend to get battered and soiled from handling, and require frequent washing, and relatively frequent painting to keep them looking at their best. Under these circumstances, they seem best suited for only the most infrequent use.

Where maximum privacy, and flexibility of a permanent nature are indicated, an accordion folding door (called room dividers or movable

walls in floor to ceiling sizes) would present an ideal solution. Folding room dividers operate in tracks fastened to the ceiling—in their "stacked" or folded position, they rest compactly out of the way against the wall—and with very little effort, they can be extended across the room to form two separate rooms in a matter of seconds.

Since the track must be permanently secured to the ceiling, the path of the door remains fixed. On the other hand, storage and handling problems are eliminated, and maintenance—except for an occasional washing, as with permanent walls—is non-existant. Perfect sight privacy is obtained, along with partial sound privacy; and where sound privacy approaching fixed wall construction is required, special sound insulating liners can be built into the door. The sound liner is installed between the steel frame and the vinyl-coated fabric cover of the door, and does not affect its appearance or operation.

In other words, folding doors literally provide the professional office with a movable wall that quickly and easily provides an "extra" room when it's needed, or folds out of the way for normal activities.

J. D. KENISON

CONVERSION HYSTERIA AND PSYCHOSOMATIC DISORDER

There is a persistently high incidence of physical symptoms due to emotional disturbance and without related ascertainable structural lesions. In rural areas, these symptoms often continue to assume the forms described by Charcot† in the last decades of the nineteenth century in Paris, whereas in urban areas unresolved emotional tension often finds discharge through the autonomic nervous system with excessive stimulation of innervated visceral structures and symptoms resulting from this. The physical symptoms described by Charcot, the gross paralytic, spasmodic and convulsive motor disturbances, the exaggeration or loss of sensation, sometimes blindness, deafness or mutism, were studied by Freud intensively. He showed that these symptoms were substitutes for ideational and feeling representation in consciousness of frustrated sexual wishes and fantasies which could not be acknowledged by the patients because of their conflicting with inner unconscious and conscious forces related to conscience. Indeed the symptoms also represented indirectly these repressive forces of conscience, causing great pain and suffering in consequence.

Freud* found ways to enable memories connected with repressed wishes and fantasies to achieve conscious recognition, simultaneously affording an outlet for strangulated affects through speech. The emotional tension was thus relieved in the psychotherapy, and the symptoms subsided in the process.

Freud later discovered that the memories related to the symptoms were themselves related to experiences dating back to childhood. These childhood experiences were reported to Freud as sexual seductions by adults. Freud came to realize that very often such events had not really occurred. What was reported as an experience was often, though not always, a childhood fantasy of something strongly wished and deeply feared, or an extravagant childhood fantasy based on an early experience. In evolving his concepts of hysteria, Freud came to the view that in all its protean forms it was related to the climax of the early family drama, the so-called oedipus situation, or more concretely to the child's struggle to surmount incestuous genital and hostile strivings of early family life. The symptoms were then understood at a deeper level as substitutes for ideational representation of these strivings, and could be translated back into word language with accompanying affective expression. At the same time, Freud emphasized that the symptoms indirectly represent (or symbolize) the defensive force in conflict with the derivatives of instinctual impulses and the retribution or punishment for forbidden wishes.

Some conversion symptoms, in conformity with this basic focus in underlying psychopathology, represent a materialization of unconscious fantasies concerned with forbidden sexual wishes. Genitalization may consist of tissue changes, including hyperemia and swelling, representing erection; of muscle spasms, representing the movements of coitus, or of sensations resembling genital sensations, although these are often complicated by the perception of pain. On the other hand, as, for example, in convulsive attacks, the symptoms

†Charcot, G. M.: Lecons sur les Maladies du Systeme Nerveux. Paris, 1873.

*Freud, S.: My views on the part played by sexuality in the aetiology of the neuroses. Collected Papers, 1:272-283, 1905.

may represent the reactive rage due to frustration of sexual wishes.

Marmor‡ has recently emphasized that in many cases of hysteria, fixations in the oedipal period are themselves the outgrowth of pre-oedipal fixations, chiefly of an oral nature. He writes:

"The kind of parent who keeps a child at an 'oral level' is apt to be the kind of parent whose behavior favors the development of a strong oedipus complex. The pre-oedipal history of most of the hysterics I have seen has revealed one of two things, either intense frustration of their oral-receptive needs as a consequence of early defection or rejection by one or both parent figures, or excessive gratification of these needs by one or both parent figures."

In recent years the influence of the early mother-child relationship upon ego-development has received increasing attention, especially in respect to the development of an adaptability in adult life which obviates the need for neurotic regression. It is important to realize that, for example, the predisposition to hysteria is built up very largely from undue emotional attachment to one or both parents with difficulty in later displacement of this attachment to a suitable human partner.

We live in an era of considerable cultural change including a wider dissemination of education, a decrease in prudery and secrecy about sex and an increase in understanding that physical symptoms can result from emotional disturbance. Now often somatic and physiologic expressions of emotional disturbance seek deeper and more disguised avenues of discharge. For when the attempted symbolic resolution of an emotional conflict in body-language begins to communicate as much, or nearly as much, as word-language to the patient himself as well as to those in his particular life-space, the attempt may immediately become abortive. The unresolved tension may then later result in discharge through the autonomic nervous system with excessive stimulation of innervated visceral structures. In this way, an increased incidence of psychophysiologic disorder may occur in the urban population, replacing the classic forms of neurosis prevalent in the time of Charcot in Paris.

Classic forms of hysteria continue in heavy incidence, however, in the rural areas of this country. Examination of such instances of classic hysteria often reveals that the familial style of life, including sleeping arrangements, results in the relatively frequent early observation by the children of sexual scenes between the adults. This "primal scene" exposure is associated with heightened difficulty in surmounting the oedipus complex, and a later vulnerability to frustration so that major classical hysterical attacks occur§.

While Freud's work on the meaning of hysteria, together with the work of other medical pioneers such as Havelock Ellis, led to less prudery and hypocrisy about sex, the work had other important lessons for mental hygiene. In particular, it became evident that early exposure to sexual scenes, or for that matter to sexual instruction, before readiness had developed for this in the developing ego, led to damaging rather than helpful effects. Premature sexual excitation stimulated by adult behavior can have a traumatic effect, and can establish the soil out of which further emotional excitation in later years yields more or less intensive morbid phenomena. It would nowadays seem necessary to bring these possibilities to the notice of "enlightened" parents, some of whom are overanxiously permissive about the curiosity of their children. It also is indicative of the need to improve the housing conditions of the less educated, and less sublimated, members of the community. These are important aspects of the promotion of healthy development of children and the prophylaxis of adult neurosis.

AMERICAN GOITER ASSOCIATION OFFERS VAN METER PRIZE AWARD

The American Goiter Association is again offering the Van Meter Prize Award of $300.00 to the essayist submitting the best manuscript of original and unpublished work concerning "Goiter—Especially its basic cause." Studies may relate to any aspect of the thyroid gland in all of its functions in health and disease. The Award will be presented at the Fourth International Goiter Conference, London, England, July 5-9, 1960. A place on the program will be reserved for the winner if he can be present at the meeting. For 1960, the recipient of the Award will receive consideration for an award of a travel honorarium.

The competing essays should not exceed 3,000 words in length, must be presented in English, and may cover either clinical or research investigations. Duplicate typewritten copies, double spaced, should be sent to Secretary, Dr. John C. McClintock, 149½ Washington Avenue, Albany 10, New York, before January 1, 1960.

President's Letter

CLOSED PANEL PLANS VERSUS FREE CHOICE OF PHYSICIAN

In recent action taken by the AMA House of Delegates in Atlantic City, New Jersey, the recommendations presented in the report of the Commission on Medical Care Plans were modified and adopted. Reaction to the AMA action was immediate and varied. "AMA does about face," and "After years of bitter opposition to closed panel health care plans, the AMA has made a significant modification of its position" were but two of the many editorial observations. The tone of most of these comments would make it appear that the medical profession has finally accepted as inevitable, closed panel medical practice.

The following statement, dealing with the definition of free choice of physician, was adopted by the AMA House of Delegates.

"The American Medical Association believes that free choice of physician is the right of every individual and one which he should be free to exercise as he chooses. Each individual should be accorded the privilege to select and change his physician at will or to select his preferred system of medical care and the American Medical Association vigorously supports the right of the individual to choose between these alternatives."

The AMA House pointed out the significance of free choice as follows.

" 'Free Choice of Physician' is an important factor in the provision of good medical care. In order that the principle of 'free choice of physician' be maintained and be fully implemented, the medical profession should discharge more vigorously its self-imposed responsibility for assuring the competency of physicians' services and their provision at a cost which people can afford."

Minnesota's position on free choice was made clear in the majority report of the Committee on Medical Care Plans presented by Chairman Herbert Plass, M.D., at the recent 106th Annual Meeting of the Minnesota State Medical Association.

The report emphasized that "the Minnesota State Medical Association emphasize its stand strongly, upholding the free choice of physician as a concept to be considered as a functional principle to the best medical care." The Minnesota recommendations further stated in part:

"We would like to emphasize strongly that we are opposed to so-called 'closed panel plans' which limit the free choice of physician. We are cognizant of the fact that in certain areas these plans are operating successfully to fulfill an apparent need. In these areas, the 'free choice of physician' has been necessarily jeopardized. Nevertheless, it is our opinion that alternative plans can be developed through the cooperation of medical societies and the individuals involved which will obviate the need for these so-called 'closed panel plans.' Furthermore, we would like to re-emphasize the inherent danger to the future quality of medical care which is likely to be associated with the further development and spread of these closed panel plans."

What will be the future of closed panel medical practice and the free choice of physician as it presently exists in light of these recent state and national actions? Have the pending implications of these actions been correctly interpreted by outside observers who can see what we of the medical profession are unable to sense? Only time will tell.

THE DOCTOR'S PLAN—VOLUNTARY HEALTH INSURANCE EXPLAINED

The following is the text of an address, "The Doctor's Plan—Voluntary Health Insurance," presented by L. A. Orsini, Vice Chairman of the Health Insurance Council, at the April 6, 1959, meeting of the Hennepin County Medical Society in Minneapolis.

* * *

Through the stimulation of competition and the demands of various consumer groups the overall pattern of financing medical care is today enmeshed in a process of evolution. It is understandably difficult for the practicing physician to stay abreast of this rapidly changing picture with the numerous other demands on his time flowing from the desire and need to provide his patients with the best medical care.

The growth of voluntary health insurance and its distribution among different types of insuring organizations clearly demonstrates that the public wants the high quality medical care which modern medicine offers and has confidence in the ability and ingenuity of the voluntary system to develop the most economic and effective methods of financing such care.

This confidence and support has been developed through a system which has preserved for the public the right to choose whether or not to buy insurance. It has stimulated experimentation in insurance coverage design which assures the individual of a wide choice of alternatives in selecting those coverages which best fit his needs or circumstances and assures continued progress in our efforts to offer broad coverage at reasonable cost. This is being accomplished for the most part in a manner which recognizes and strengthens present concepts of the free practice of medicine.

The issues are clear, the relationships of health insurance to the financing of medical care is firmly established, the question we face is whether the ultimate answer will be provided through the continued expansion and growth of the voluntary system or a government operated program. It is apparent therefore, that on this point we stand or fall together. Since our destinies are at stake, I want to discuss with you some of the responsibilities we must assume to influence the public's choice.

First let's look at where we are with respect to the two main criteria used to evaluate our voluntary health insurance system:

1. Making coverage available to all who want and can afford to buy it.
2. Providing broad coverage at reasonable cost.

Today about seven out of ten persons have some form of health insurance. The true significance of this accomplishment is apparent when we recognize that the remaining 30 per cent is made up, in part, of those who do not need, want, or believe in (for religious or other reasons) health insurance; and others who are institutionalized in government financed mental, chronic illness or tuberculosis hospitals or receive care from the Veteran's Administration, Medicare and other government sponsored programs. Furthermore, additional progress seems assured in this area with the development of new methods for extending the economics of group insurance to more people and extending coverage to physically impaired risks and our senior citizens.

Obviously, the problem of financing hospital and medical care for the retired aged is a subject of real concern, not only because of its social significance, but also because it is the point on which the survival of our entire voluntary system of providing and financing health care may ultimately be resolved.

It is important that any evaluation of the potential of voluntary health insurance in meeting this problem be carried out objectively and dispassionately with a full realization of the fundamental superiority of a private operated system over similar government programs.

Here are some of the important facts:

1. *What is being done?*

Seven principal methods are being employed to provide health insurance to older persons. They are: (a) Continuation of insurance on older active workers under group insurance plans. (b) Continuation of group insurance on workers who retire and their dependents, generally with part or all of the premium paid by the employer. (c) Continuation on an individual policy or contract basis, of coverage originally provided by group

insurance, this being accomplished by conversion of the group coverage on termination of employment or membership in the insured group. (d) New issuance of group insurance on such groups of older people as associations of retired persons or employees, retired teachers and civil servants and Golden Age Clubs. (e) Continuation into the later years of individual insurance purchased at the younger ages. (f) New issuance of individual insurance at advanced ages. (g) Issuance of insurance that becomes paid up at age sixty-five, thus enabling the policyholder to pay for his protection during his productive years.

2. *What is the current status?*

The number of older people having some form of health insurance today is not known precisely. Generally, it is accepted that at least 40 per cent of the persons over sixty-five now have some form of health insurance.

It is also important to recognize that about 16 per cent of the aged are public welfare recipients under the federally aided public assistance programs and as such are eligible to receive health care. This group is and should be government's responsibility.

3. *What progress has been made?*

For the ten-year period (1946-1956) the population in the sixty-five to sixty-nine age bracket covered by hospital expense insurance increased from 15 to 48 per cent; in the seventy and over bracket, the increase was from 5 to 30 per cent. Furthermore, I believe you find that current figures support a trend of continued progress. This stems from the increased awareness of both management and labor of the need to continue health insurance protection after retirement and the development of new coverages and techniques through which the individual may acquire coverage at the older ages. This assumption is re-enforced by the fact that recent studies have shown that coverage for the aged has been increasing at the rate of about 3 per cent per year.

4. *What are some of the recent significant developments in this area?*

Certainly the action of the American Medical Association at its Clinical Session here in Minneapolis last December is a development of great significance and potential. As you know, this resolution has placed in your hands the initiative for encouraging the development of ". . . effective voluntary health insurance for the group over sixty-five with modest resources. . . ."

It is vitally important that the conditions under which this principle is implemented recognize the need to preserve the public's freedom to choose the type of insurance protection, if any, it wishes to have with adequate information to make that choice intelligently. Thus, medicine should not endorse any single mechanism as the exclusive instrument for providing financial protection to the aged.

I believe you should carefully consider whether in the final analysis the most effective contribution you can make in this critical area is the identification of average fee levels for persons of defined modest resources which would apply irrespective of the source of financing whether it be earnings, savings or insurance or any combination thereof. One thing is clear, this is an area in which there is an urgent need for us to work together.

The complex and rapidly changing patterns of medical and hospital care with their accompanying increased cost are influencing the design of health insurance. While the bulk of the insurance in force today still conforms to the basic hospital surgical and medical care approach a need has clearly emerged for broader coverage at a reasonable cost. This objective is brought into sharper focus by a definition of the terms "broad coverage" and "reasonable cost."

There are many variations in such definitions, however, with the insurance industry, there is general agreement in that:

1. The plan should cover virtually all types of medical, hospital and other expenses which may be encountered during the course of an illness, in recognition of the wide range of technical skills, medical techniques, and expensive drugs involved in modern medicine.

2. The plan should recognize and support those concepts within medicine which have enabled the public to enjoy the finest medical care. This is accomplished by—(a) Encouraging free choice of physician. (b) Embracing quality standards of medical care developed by doctors and hospitals. (c) Recognizing the right of the physician to determine the cost of his service and the type and amount of care needed.

3. The plan should require the insured to share in the total expenses so that premium costs might be maintained at a reasonable level. This is done through deductibles and coinsurance provisions on the assumption that the former will operate to screen out the smaller expenses leaving the major portion of the premium dollar to finance the larger expenses which may be such a hardship to the individual. The coinsurance provision requires the continued financial participation of the insured in his medical care bill (generally 20 per cent) to work against pressures for luxury accommodations or other unnecessary services which would otherwise unnecessarily inflate premium costs.

As you know "Major Medical Coverages" have generally embraced all of the principles previously cited. It is unique in this respect as well as in the fact that it has imposed new responsibilities on doctors, hospitals and the insurance carriers to exercise leadership in making such insurance arrangements work most economically and effectively for the public.

The increasing cost of medical care is receiving increased public attention. Unfortunately, much of the national publicity in this area has incorrectly identified such increases with alleged inefficiency and waste, creating confusion and misunderstand-

ing and jeopardizing the public's acceptance of our voluntary system. Furthermore it is not generally realized that for the most part the increased cost of medical care can be identified with the better health that comes to us all as a result of advances in medical science. Economic inflation is another important contributing factor but it is one over which we have no direct control. Nevertheless, we should not overlook the need to assure the public that we are aware of wasteful practices and that we are taking aggressive steps to eliminate them. Here too, it must be recognized that this responsibility is jointly shared by the doctor, hospital, insured public and the insuring organization, and that the answer rests with the ability of all parties to work together with a full recognition of their relative responsibilities and a willingness to deal with them forthrightly.

To effectively meet this problem I would propose that representatives of the medical profession, hospitals and insurers seize the initiative and jointly develop a plan to (a) identify such practices as overcharging, inefficient use of insured services and other wasteful practices. (In this respect, I am confident that facts will show that problem has been grossly overemphasized by the negative publicity to date); (b) establish such machinery as may be necessary to correct specific cases involved; (c) promote a series of educational programs in cooperation with labor and industry in your area to bring about a better understanding of insurance and what is being done to make the voluntary system work better for the public.

I would like to touch briefly on the subject which has been the number one irritant to the medical profession, namely, claim forms. The insurance industry in cooperation with medicine has developed a set of simplified claim forms through which we hope to streamline the form completion responsibilities you have assumed. We are promoting the widespread use of these forms both within the insurance industry and the medical profession. Recently a booklet describing this program was directed to your attention. This program is already receiving the support of insurance companies writing 80 per cent of the group business and 50 per cent of the individual business. Much progress has been made and more will come with your co-operation, patients and understanding.

In retrospect, you will note that several times in my discussion this evening I have focused the need for co-operation between insurance and medicine. In recognition of this need the insurance industry, through the Health Insurance Council, has established a network of state committees made up of knowledgeable capable insurance company representatives. The Chairman of your Minnesota Committee is here tonight. I know he joins me in the hope that you will look to this committee as your primary contact with the health insurance industry and as the forum through which problems will be resolved and a climate of mutual respect and understanding will be developed.

American Medical Association

Resume of 108th Annual Meeting

President Dwight D. Eisenhower, speaking at the Presidential Inauguration ceremony of the 108th Annual Meeting of the AMA held June 8-12 in Atlantic City, New Jersey, urged American physicians to protect the "private arrangement between doctor and patient" without which "we shall all have suffered a great loss."

Speaking at the occasion at which Doctor Louis M. Orr, Orlando, Florida, became the 113th president of the American Medical Association, President Eisenhower warned that inflation posed the greatest danger to the traditional free enterprise practice of medicine. He said, "The cost of inflation is not paid in dollars alone, but in increasingly stagnated progress, lost opportunities, and eventually, if unchecked, in lost freedoms for the doctor and the patient."

Mr. Eisenhower told the over-flow group of 5,000 persons assembled in the Convention Hall, that he was "indeed gratified" to learn of medical leadership in meeting the health problems of the aged. The chief executive also noted that the AMA has "embarked upon an all-inclusive program to re-orient our thinking about the place of elder citizens in modern society and to help them meet their health care needs."

"In health as elsewhere in American life," he said, "our summons to greatness calls for a lively partnership of individual effort with action by voluntary agencies and private enterprise and, where necessary, government action at appropriate levels."

Special concern was expressed by Mr. Eisenhower regarding unchecked inflation and its relationship to older people who live, to a great extent, on fixed retirement incomes as represented by pension, insurance policies, and savings. Commenting on this matter, the President said "to this group, inflation is not merely a threat—it is a robber and a thief. It takes the bread out of their mouths, the clothes off their backs, and it limits their access to the medical care and facilities they need."

Doctor Orr Becomes 113th President

Doctor Orr, in his inaugural address, re-affirmed his belief in the basic principles of medicine, democracy and faith unto which America's physicians live today. He pointed out that physicians as citizens, believe in individual freedom, rights and responsibilities.

According to Doctor Orr, "the basic element of progress is not compulsion but voluntary cooperation; not force but reason; not blind obedience but independent intelligence; not timidity but faith—in man, in ourselves and in God."

Dr. Orr pointed out that freedom must continually be fought for by men and women who are willing to stand up and be counted.

The new AMA President particularly stressed the importance of caring for the older citizen. We must "improve and broaden voluntary health programs in preference to compulsory programs that lead to waste," concluded Doctor Orr.

He reminded the audience that they must "defend the unfettered, inquiring mind, for medical progress depends upon the relentless quest for truth by minds that are free."

Actions of AMA House of Delegates Reviewed

Dr. Gunnar Gundersen, La Crosse, Wisconsin, retiring AMA President, told the delegates in his President's Report, that we must be ready to deliver "1959 medicine" intelligently and skillfully. He noted that it is the personal responsibility of every physician to keep abreast of medical advancements.

Doctor Gundersen said physicians must do their "homework" to be prepared for any medical situation by reading scientific journals, attending scientific meetings, participating in the graduate and refresher courses and utilizing every other mechanism of professional education.

In commenting on AMA efforts to advance scientific medicine, Doctor Gundersen pointed out that fifteen of the nation's top scientists will form an *ad hoc* committee to objectively evaluate and advise on the Association's future programs. He pointed out that as a result of the recent AMA progress, he had come to believe that the Association is better prepared to serve both the public and the profession than ever before.

Doctor Gundersen expressed enthusiasm regarding recent developments in the field of health insurance for senior citizens. Blue Shield plans, he said, immediately responded to AMA's call for development of low cost medical coverage for people over sixty-five. He further pointed out that the AMA is expanding its working liaison with all insurance groups through the Health Insurance Council.

Doctor Gundersen strongly emphasized that the medical profession and the insurance industry must cooperate closely in creating plans that best serve the medical and economic needs of the public. Physicians must adhere to the principle of

charging for professional service on a basis that permits the insurance industry to sell health insurance at a price people can afford to pay.

In conclusion, the retiring AMA President commended the campaign against food faddism, and praised the Food and Drug Administration and the National Better Business Bureau for their cooperative efforts in this project.

Commission on Medical Care Plans

The House of Delegates received Part I of the report of the Commission on Medical Care Plans as information only and then acted upon the Commission recommendations item by item. The House adopted thirty-six of the recommendations without change, but reworded three which relate to miscellaneous and unclassified plans. The changed recommendations now read as follows:

B-4. In an effort to decrease, or at least to prevent an increase, in the over-all cost of health care, study should be given to the removal of the requirement of hospital admission as the only condition under which payment of certain benefits will be made.

B-6. Medical care plans should be encouraged to increase their efforts to provide health education and information concerning the coverage of their subscribers.

B-16. The American Medical Association believes that free choice of physician is the right of every individual and one which he should be free to exercise as he chooses. Each individual should be accorded the privilege to select and change his physician at will or to select his preferred system of medical care and the American Medical Association vigorously supports the right of the individual to choose between these alternatives.

In connection with free choice of physician, the House also requested the Board of Trustees to transmit to all constituent medical associations the "far-reaching significance" of Recommendation A-7, which says:

"Free choice of physician" is an important factor in the provision of good medical care. In order that the principle of "free choice of physician" be maintained and be fully implemented, the medical profession should discharge more vigorously its self-imposed responsibility for assuring the competency of physicians' services and their provision at a cost which people can afford.

The House also strongly endorsed Recommendation B-11, which declares:

Those who receive medical care benefits as a result of collective bargaining should have the widest possible choice from among medical care plans for the provision of such care.

Many of the Commission recommendations urged increased activity by state and county medical societies and the American Medical Association in such fields as continuing study and liaison, closer attention to legal and legislative factors, and the development of guides for the relationship between the medical profession and the various types of third parties. To carry out three of the recommendations involving AMA activities, the House also approved a seven-point program which it requested the Board of Trustees to transmit to the Division of Socio-Economic Activities for immediate attention.

Medicine and Osteopathy

In considering a special report of the Judicial Council on the subject of osteopathy, the House adopted the following policy statement regarding interprofessional relations:

(A) All voluntary professional associations between doctors of medicine and those who practice a system of healing not based on scientific principles are unethical.

(B) Enactment of medical practice acts requiring all who practice as physicians and surgeons to meet the same qualifications, take the same examinations and graduate from schools approved by the same agency should be encouraged by the constituent associations.

(C) It shall not be considered contrary to the Principles of Medical Ethics for doctors of medicine to teach students in an osteopathic college which is in the process of being converted into an approved medical school under the supervision of the AMA Council on Medical Education and Hospitals.

(D) A liaison committee be appointed by the Board of Trustees of the American Medical Association to meet with representatives of the American Osteopathic Association, if mutually agreeable, to consider problems of common concern including inter-professional relationships on a national level.

In another action concerning osteopathy, the House recommended that the American Medical Association representatives on the Joint Commission for the Accreditation of Hospitals suggest to the Joint Commission that they inspect upon request and consider for accreditation without prejudice those hospitals required by law to admit osteopathic physicians to their staff.

Preparation for General Practice

The House approved and commended the final report of the Committee on Preparation for General Practice, which proposes a new two-year internship program for medical school graduates planning to become family physicians. To avoid unnecessary confusion, the House deleted only one sentence which read: "Indeed, the committee believes that the one year internship actually encourages inadequate preparation for general practice." The Committee on Preparation for General Practice included representatives from the AMA Council on Medical Education and Hospitals, the American Academy of General Practice and the Association of American Medical Colleges.

The suggested program would include a basic minimum of eighteen months hospital training in the diagnostic, therapeutic, psychiatric, preventive and rehabilitative aspects of medicine and pediatrics in a very broad sense, including care of the newborn. A physician then could elect to spend the remaining six months for additional training in other segments of the program. The commit-

tee stated, however, that participants who plan to practice obstetrics would be expected to spend at least four months of the elective period in obstetrical training.

The report declared that "the graduate program of two years in preparation for family practice should be planned and implemented as a unified whole" with a maximum continuity of assignment in specific services. The program also calls for adequate experience in outpatient care and emergency room service.

Social Security

In considering five resolutions on the subject of compulsory Social Security coverage for self-employed physicians, the House disapproved of four and adopted one reaffirming its opposition to the compulsory inclusion of physicians. In so doing, the delegates expressed concern over the possible effects that a change of policy might have on the Association's entire legislative program, particularly with respect to the Forand Bill.

The House also recognized "the apparent growing demand by physicians for economic security" and requested the Board of Trustees to investigate the possibilities of developing group insurance and retirement plans which could be made available to Association members. It accepted a reference committee suggestion that "the American Medical Association continue and expand its educational program to inform its members of the economic, social and moral advantages of economic security obtained within the framework of our free enterprise system rather than through the mechanisms of governmental Social Security."

Miscellaneous Actions

In dealing with a wide variety of other subjects, the House also: Urged all physicians to participate more fully in community activities and *socio-economic matters* in their own communities but agreed that no change should be made at this time in Article II of the Constitution, which states Association objectives;

Approved in principle the aims and objectives of the President's Council on *Youth Fitness* and the Citizens Advisory Committee on the Fitness of American Youth;

Accepted a Board of Trustees recommendation that the *1962 Annual Meeting* be held in Chicago;

Expressed heartfelt thanks to the Committee on *Amphetamines* and Athletes, which has completed its assignment;

Requested the Board of Trustees to study the problems and possibilities of establishing an AMA—sponsored *medical scholarship* and/or loan program;

Approved the inclusion of *Today's Health* as a benefit of dues-paying membership and urged members to make it available to their patients;

Recommended that state medical societies, where advisable, initiate legislative efforts to eliminate *cancer quackery;*

Received a progress report indicating "phenomenal progress" in the field of health insurance coverage for *the aged* since the Minneapolis meeting last December;

Gave a rising vote of thanks to *Dr. Joseph D. McCarthy,* who finished his term as chairman of the Council on Medical Service;

Reaffirmed its full support of the Educational Council for *Foreign Medical Graduates;*

Endorsed the purposes outlined in the initial report of the *Medical Disciplinary Committee;*

Urged every AMA member to give a substantial gift to the *medical schools* through the American Medical Education Foundation; and

Expressed appreciation for the outstanding *disaster medicine* program presented by the United States Army Medical Service on June 6, 1959, in Atlantic City.

Election of Officers

Dr. E. Vincent Askey, Los Angeles, California, Speaker of the House of Delegates since 1955, was named president-elect to succeed Doctor Orr as president at the American Medical Association Annual Meeting in June, 1960, in Miami Beach, Florida.

The following officers were also elected at the Thursday session: Dr. J. Stanley Kenney, New York City, Vice President; Dr. Norman A. Welch, Boston, Massachusetts, Speaker of the House of Delegates; and Dr. Milford O. Rouse, Dallas, Texas, Vice Speaker of the House of Delegates.

Dr. R. B. Robins, Camden, Arkansas, and Dr. Hugh H. Hussey, Jr., Washington, D. C., were re-elected for five-year terms on the Board of Trustees. Also elected to the Board, for the first time, was Dr. Percy E. Hopkins, Chicago, Illinois.

Dr. J. M. Hutcheson, Richmond, Virginia, was re-elected to the Judicial Council. Re-elected to the Council on Medical Education and Hospitals were Dr. Charles T. Stone, Sr., Galveston, Texas, and Dr. W. Andrew Bunten, Cheyenne, Wyoming.

Dr. Willard Wright, Williston, North Dakota, was elected, and Dr. J. Lafe Ludwig, Los Angeles, California, was re-elected to the Council on Medical Service. Dr. William Hyland of Grand Rapids, Michigan, was re-elected to the Council on Constitution and Bylaws.

Minnesota State Medical Association

Highlights of Actions Taken by the House of Delegates

Dr. Clarence Jacobson, surgeon and general practitioner, from Chisholm, was elected President-Elect of the Minnesota State Medical Association at the final session of the House of Delegates held in conjunction with the 106th Annual Meeting. Doctor Jacobson will succeed Dr. Benjamin B. Souster, January 1, 1960.

A native of Duluth, Doctor Jacobson is a 1916 graduate of Duluth Denfield High School. He attended St. Olaf College in Northfield and received his medical education at the University of Minnesota. He entered general practice in Chisholm in 1928 and is currently president of the Adams Clinic.

Doctor Jacobson was one of the leaders instrumental in the formation of the Range County Medical Society. Prior to the organization of that group, he served as president of the Range Division of the St. Louis County Medical Society.

Doctor Jacobson is a member of the American College of Surgeons.

Other officers elected are the following: William G. Macklin, M.D., Willmar, First Vice President; Brian J. McGroarty, M.D., St. Paul, Secretary; Karl W. Anderson, M.D., Minneapolis, Treasurer; Haddon M. Carryer, M.D., Rochester, Speaker of the House of Delegates; John L. Falls, M.D., Red Wing, Vice Speaker of the House of Delegates; J. N. Stickney, M.D., Rochester, Councilor at Large; Walter B. Wells, M.D., Jackson, Second District Councilor; O. J. Campbell, M.D., Minneapolis, and Albert E. Ritt, M.D., St. Paul, delegates to the American Medical Association; C. L. Oppegaard, M.D., Crookston, alternate for Dr. Campbell; and E. M. Hammes, M.D., St. Paul, alternate for Dr. Ritt.

Fifty-Year Members Honored

Fifty-three members of the Minnesota State Medical Association who, in 1959, completed fifty years of medical practice in Minnesota, were honored at the Annual Banquet held in conjunction with the 106th Annual Meeting.

Twenty-seven half-century mark physicians were in attendance to receive their citations. Presentations were made by Dr. Haddon M. Carver, Rochester, Speaker of the House of Delegates.

New members of the Fifty-Club are:

Minneapolis—Archabald L. Arends, M.D.; Clifton A. Boreen, M.D.; Charles N. Brooks, M.D.; Richard R. Cranmer, M.D.; Henry D. Diessner, M.D.; Charles R. Drake, M.D.; George E. Fahr, M.D.; Edgar J. Huenekens, M.D.; Rae T. LaVake, M.D.; Henry P. Linner, M.D.; Daniel MacDonald, M.D.; Stanley R. Maxeiner, M.D.

St. Paul—George A. Earl, M.D.; Edward W. Ostergren, M.D.; Robert B. J. Schock, M.D.; Edward Schons, M.D.; Alex Stewart, M.D.; Harry B. Zimmerman, M.D.

Duluth—Leon A. Barney, M.D., Arthur N. Collins, M.D.; Frank J. Hirschboeck, M.D.; Francis J. Lepak, M.D.; Archibald L. McDonald, M.D.

Rochester—George B. Eusterman, M.D.; Arrah B. Evarts, M.D.; Dorr F. Hallenbeck ,M.D.; Henry W. Meyerding, M.D.

Outlying Minnesota—Almer M. Aanes, M.D., Red Wing; Roy N. Andrews, M.D., Mankato; Clarence S. Bossert, M.D., Mora; Thomas E. Flinn, M.D., Remer; Raymond T. Healy, M.D., Pierz; Garfield E. Over Sixty-five Health Insurance

Health insurance for persons over the age of sixty-five, adoption of a relative value study, and approval of an impartial medical testimony plan were among important items of business to receive the attention of the House of Delegates at the 106th Annual Meeting of the Minnesota State Medical Association in Duluth.

The recommendations of the Committee on Medical Service were accepted in general by the Council. The House of Delegates approved the plan for over sixty-five health insurance submitted by the chairman of the Council.

Major provisions of the plan include elimination of the sixty-five year age limit; substitution of a 120-day for the current 180-day period of

hospitalization; a six-month waiting period for pre-existing ailments; diagnostic x-ray to be covered in the doctor's office if followed by hospitalization; income limits of $2,400 for single persons and $3,600 for man and wife; net worth limits for complete service benefits of $20,000 for single persons and $30,000 for man and wife; participating physicians to be paid on the same schedule as is used in the basic Plan A contract; and, finally, an estimated cost to subscribers of about $2.00 a month.

The adoption plan has been forwarded to Minnesota Blue Shield for review and implementation. Remaining to be solved is the matter of providing a matching contract for hospitalization of the aged. Currently negotiations regarding this phase of medical care for the aged are in progress between Minnesota Blue Cross and Minnesota Blue Shield.

Blue Shield Contract Changes Proposed

Two important extensions to the standard Blue Shield contract were also approved by a special "go-ahead" action of the House.

The first provided for an extension to the basic contracts for covering major medical expense, and would become effective after benefits of basic Blue Shield contracts have been exhausted. The proposal also provides for a "corridor". Also included is the "coinsurance feature" which requires the patient to pay a portion of the bill himself.

The other extension would provide out-of-hospital coverage for diagnostic x-ray and diagnostic laboratory services, up to a cost of fifty dollars each for Plan A subscribers and seventy-five dollars each for Plan B subscribers.

The Blue Shield Board had urgently requested immediate action, especially for the major medical expense extension although details were not fully worked out. The Council felt that additional time was needed for essential study before House approval could be recommended for the two plans. For that reason, the Chairman of the Council informed the House of the situation at the Monday session and asked the delegates for authority to approve the plans after proper consideration had been given, and if such action seemed warranted on the basis of such consideration. Acting on the permission of the House, which was unanimously given, the Council has now studied both plans and has approved both of them in principle. Both extensions will be sold, with Council sanction, as soon as details can be worked out and that sanction carries with it the sanction, also of the House of Delegates.

Relative Value Study

The House voted its approval in principle to a relative value study. The study is similar to one adopted in California.

It is important to note that adoption of this study does not mean that the delegates had voted to inaugurate a fee schedule for Minnesota nor does it mean that a standard unit of value was set up to be used as the basis for the schedule.

The relative value study was adopted in order that it may be used as a guide in determining fees. It was also suggested that such a guide might be useful particularly for insurance companies and for physicians who are entering practice.

Impartial Medical Testimony

Unanimously approved, in principle, by the House of Delegates was a method of handling impartial medical testimony in the state of Minnesota. The method approved is called the New York Plan for Impartial Medical Testimony. Later this plan also received approval of the Minnesota Judges Association.

Many details still must be worked out co-operatively by the Medical Advisory Committee, the Minnesota Judges Association and the Minnesota State Bar Association before the plan can be inaugurated.

The method stipulates that medical associations select physicians who are qualified to give expert medical testimony in various fields of medicine. Judges who are disturbed by the quality or the conflict in medical testimony given in their courts or in pre-trial conferences would then look for assistance to panels comprised of these physicians.

By-laws Change

Six amendments to the By-laws were adopted at the Duluth meeting and will be published as adopted in MINNESOTA MEDICINE.

Amendments adopted provide for the territorial jurisdiction of county and district medical societies; with membership for medical missionaries outside the United States and also with residency memberships (one restriction on such membership having been lifted in accordance with action taken by the House last year); the mechanics for proposing amendments to the By-laws; with authority of the House of Delegates to adopt new principles of medical ethics; and with the establishment of new dates on which dues to the Association will become due and delinquent.

Miscellaneous Resolutions

A number of miscellaneous resolutions were also passed. Two provided for definite responsibility of county medical societies in the civil defense program. Another stipulated that more emphasis should be placed on the teaching of medical problems of the aged in the University of Minnesota Medical School.

In another resolution, the essay contest sponsored annually by the Association of Physicians and Surgeons was also approved, provided the county medical societies concerned wish to promote this project in their individual groups. The decision to participate was granted to the individual county society.

The Art of Medicine

GOOD GUEST SPEAKER RELATIONS ARE IMPORTANT

Is there a guest speaker scheduled for the next medical society meeting? The American Society of Association Executives makes the following suggestions in the interest of good guest speaker relations:

Make your request and make definite arrangements about the fee. If there are expenses involved, tell him quite plainly what expenses you will pay. In your letter or talk include date, time and place, type of speech or subject, length of speech, question or answer period later, type of meeting you're holding, description of your group, type and size of audience, and description of program.

Once the speaker has accepted invitation and confirmed the fee, begin the process of making him feel welcome. Don't wait until the day of his speech. Write another letter and thank him for his acceptance, ask if you can meet him on arrival, ask to make his hotel reservations, give detailed information on how to get to meeting place, send copies of advance program and promotion material, find out what equipment he needs, and tell him who else will be at the speakers' table.

Publicity is important for both of you. Send him data form for publicity information if he doesn't provide it, follow-up with newspaper clippings of any publicity, and obtain his permission if you plan to record or broadcast his speech.

A few days before the meeting send a reminder letter and again welcome him to the meeting.

When speaker arrives, have a note at his hotel telling where to contact you if you haven't met him, arrange to meet with him, as soon as you can, arrange for escort from his room or door of meeting room to the speakers' table, and pay fee immediately before or right after the meeting.

CAN YOU SUGGEST A DOCTOR?

Frequently, the state association office, as well as other county societies and individual physicians, are confronted with this question from someone seeking medical service.

Here's how the San Diego Medical Society handles such requests.

When a patient calls the San Diego County Medical Society for a physician, he is sent two or three choices and a card entitling him to a free get-acquainted visit. The card gives city newcomers and others a chance to *interview a physician at no cost to themselves and discuss the possibility of making him their family doctor.*

Message on the card reads: "The San Diego Medical Society has recommended to the public that every family should have a personal physician. Ordinarily medical fees are not assessed for such an introductory interview unless specific advice and/or treatment is instituted."

CHECKUP OR BRUSHOFF?

This three-word question was asked in the November 2, 1958, issue of the *Wichita Eagle,* Wichita, Kansas. The editorial explanation of the inquiry which accompanied the question is as follows:

We read repeatedly of major public figures going to their doctors for "a regular medical checkup." President Eisenhower did this a few days ago and was found healthy and able to take the rigors of office and campaign.

"But so often when one of us ordinary persons goes to our own doctor for a 'periodic checkup' we get a brushoff instead.

Medical literature and public health officials constantly advise that the best way of preventing disease and ailments is to have such checkups. Like the Cancer Society's admonition, 'Fight Cancer with a Check and a Checkup.'

Many doctors, for reasons of being overloaded with work or for other reasons, don't seem to take this idea seriously. They take the individual's blood pressure, tap his chest to listen, ask if he has any complaints, and then turn him out so they can deal with persons known to be ill.

Doctor Lester Breslow, chronic diseases chief of the California State Health Department, spoke up against this practice in a talk in St. Louis a few days ago. He said that it could be blamed partly on the shortage of doctors.

He added that this is a 'major challenge' to the professors of preventive medicine in our medical schools. And we're inclined to agree. Too many times we have known of someone succumbing to cancer or some other ailment when a thorough physical examination a few months before would have revealed it and allowed time for treatment."

MAKE CERTAIN THAT THERE IS A DOCTOR IN THE HOUSE Has your county medical society ever considered the possibility of volunteering its emergency service to visiting conventioners, or staffing a medical headquarters at your local county fair?

The *PR Doctor* notes that during a recent convention of the Association for Health, Physical Education and Recreation in Portland, Oregon, the Multnomah County Medical Society made its emergency call system available to all conference attendants. Announcement of the service and the telephone number were printed in meeting literature so that visitors to the convention would know how to get a doctor.

Whatever the group, if enough people are gathered, it is a fair assumption that someone is going to need medical attention, adds the *PR Doctor.*

READING RACKS INSTALLED IN DRUG STORES The Medical Society of the State of Pennsylvania has launched a co-operative project with the State Pharmaceutical Association to use drug stores for the distribution of medical public relations material.

When a local pharmaceutical association expresses interest in pamphlet distribution the state medical society dispatches a representative to explain the program to the group. If the druggists agree, each member *is supplied a pamphlet rack and a quantity of pamphlets to display in his drug store.* The society replenishes the supply periodically with up-to-date materials.

The whole operation is carefully *co-ordinated with the state pharmaceutical association.* That organization notifies its county groups of the program through its own publications and relays their interest back to the medical society. The state pharmaceutical association also supplies mailing lists and advises the medical society when to restock the druggists' literature.

Perhaps county medical societies or individual physicians may wish to discuss the possibility of such a project with a local pharmacist. The Minnesota State Medical Association will co-operate to supply appropriate public relations and public health information materials when requested.

A COMMENDABLE MOVE The Mower County Medical Society (Minnesota) has awarded its first four-year scholarship to Richard Curtin, a student in an Austin High School.

Richard, the son of Mr. and Mrs. W. A. Curtin, Austin, will receive four-hundred dollars a year for four years to attend the college of his choice if he maintains a satisfactory average. The scholarship will be awarded annually to an Austin High or Pacelli High School graduate.

Merit will be based on high scholastic attainment, need, character and intention of doing college work in the natural sciences or mathematics.

Applicants must apply in writing to the scholarship committee including Dr. T. E. Barber, Dr. A. D. Fetzek, Dr. F. H. Rosenthal, Park Dougherty and Judge Paul Kimball.

Public Health

TUBERCULIN TESTING IN MINNESOTA—1958

D. S. FLEMING, M.D., M.P.H.,
Minneapolis, Minnesota

Almost twice as many tuberculin tests were reported to the Minnesota Department of Health in 1958 as in 1957. The total of 192,434 compares with 98,900 tests reported in 1957 and 39,414 reported in 1954, the first year the present reporting system was used.

A total of 6,007 (3 per cent) of the 1958 tests were positive, and no significant difference was noted in the percentage of male and female positives. Out of 91,920 males tested, 3,047 readings were positive. The 94,507 female patients tested revealed 2,960 positive readings.

Reports are received in the state health department twice a year from district and county public health nurses and others conducting group tuberculin tests. The greater number of tests reported in 1958 can be attributed to more conscientious reporting rather than to more testing.

The bulk of the 1958 tests were conducted in surveys of 450 schools, six colleges, and 3 communities. Industry, Indian reservations, and nursing homes each accounted for two surveys. A rest home, a migrant workers' clinic, and a practical nurses' training school also participated in the testing program. The total on school testing programs is incomplete because nineteen counties failed to list the number of schools included in their summaries.

A breakdown of test results by age groups shows a rising incidence of positive readings as age increases. Out of 21,965 six-year-olds given tuberculin tests, only 198 (less than 1 per cent) were positive. Of the 34,146 tested in the fifteen to nineteen age group, 1,212 (less than 4 per cent) were positive readings.

Although fewer tests were given to older persons, the percentage of positive readings continued to rise. The 3,001 persons tested in the thirty to thirty-nine age group showed 387 (13 per cent) positive. The 1,890 persons tested in the fifty to fifty-nine age group produced 496 (26 per cent) positive, and 1,111 in the sixty and above group revealed 401 (37 per cent) positive readings.

More tuberculin testing should be done in all age groups, particularly among older persons who are most likely to develop tuberculosis. Last year, 95 per cent of the 105 persons who died of tuberculosis in Minnesota were forty-five years of age or older. The tuberculin test should be a standard procedure in health-screening examinations.

Dr. Fleming is Director of the Division of Disease Prevention and Control, Minnesota Department of Health.

The 1958 figures show a greater percentage of positive readings in male than in female patients over the age of fifteen. This probably can be explained by the fact that men usually have more opportunities for exposure to the disease because of normal occupational contacts or military service.

Very few of the children with positive Mantoux tests have active cases of tuberculosis. The reaction simply means that the child has had contact with someone having an active case of the disease and has been infected. It does not mean he is ill with tuberculosis at present, but he could become ill at some time in his life. He should receive a chest x-ray, and his contacts should be traced to find any active cases.

The tests also can be used as an educational technique. We can inform children and their parents about the use, value, and necessity of the tuberculin test for early case-finding in tuberculosis control and educate them on maintaining good health practices.

Many tuberculin tests are performed each year by physicians in offices, hospitals, and other programs which are not reported to the state health department. Submission of all such reports to the department should be standard procedure.

Method

Tabulation of 192,434 tuberculin tests reported from the State of Minnesota for 1958 compares with 98,900 tests reported in 1957, and 39,414 tests reported in 1954, the first year for which the present reporting system was used. Reports are received in the State Health Department twice a year from district and county public health nurses and others conducting group tuberculin tests. Undoubtedly additional thousands of tuberculin tests are carried out each year by physicians in their offices, in hospitals, and in other programs that

have not been reported. Such reports are welcomed and encouraged in order to increase the value of the data presented.

Testing in 1958 was accomplished in the following situations, according to reports:

Schools	450
Colleges	6
Communities	3
Industries	2
Indian Reservations	2
Nursing Homes	2
Rest Home	1
Migrant Workers Clinic	1
Practical Nurses Training School	1

The predominance of school programs accounts for concentration of tests in the school age groups. Because reports from nineteen counties failed to list the number of schools included in the county summary, the total number of school programs shown above is incomplete.

Testing of communities is carried out when evaluation of the local tuberculosis problem seems to warrant it. Of the three community tests in 1958, one included four townships in which there was an Indian population; one was a single township; and the third was two small neighboring villages.

Old tuberculin has been the material of choice for screening and has been used in 1958 entirely in eighty-nine programs. P.P.D. has been used six times, either for an entire survey or for part of the program. Some counties have two programs a year, one in the fall and one in spring. Different areas usually participate each time.

Appreciation is expressed to all those public health workers of official and voluntary agencies, volunteers, school people, physicians, and all the others in the state who have helped in this program.

AMERICAN MEDICAL ASSOCIATION DECLARES WARNINGS ON ALL HAZARDOUS CHEMICALS NEEDED

Warnings on the labels of all products containing hazardous chemicals were declared recently as the objective of a model law formulated by the American Medical Association and recently introduced into Congress. (H. R. 7352).

Speaking before the Association of Food and Drug Officials of the United States, Hotel Bradford, Boston, Mass., Bernard E. Conley, Ph.D., Chicago, secretary of the A.M.A. Committee on Toxicology, declared "If we are to educate people to read labels and obey their warnings, we must require identification of hazardous ingredients on all products, not merely on certain classes of chemicals such as pesticides."

Half of all substances causing accidental injury and death are not required by law to carry precautionary labeling. Many of these are used in the home, in small businesses and in other areas where control of harmful exposures is not as guarded as in the manufacturing process.

While three-quarters of these products contain substances which are moderately toxic or worse, most states and the federal government have no laws to require them to carry warnings or to declare toxic or other hazardous constituents, Dr. Conley declared.

There has been a growing acceptance of the need to label hazardous household chemicals. Examination of over 1,000 varieties of products revealed that chemicals used in commercial establishments, such as hotels, garages, laundries and restaurants, need the benefit of labeling as greatly as those entering the home.

Dr. Conley discounted the claim that wide use of precautionary labeling would bring about eventual disregard of all warnings. The widespread use of danger and warning signs for transportation and traffic hazards has never been considered a deterrent to safety. No one ever suggested that our mounting motor accident statistics are due to the number of safety signs about them; rather the growing number of auto accidents are related to the increasing number of motor vehicles. The same basic factors underlie the problem of accidental poisoning by hazardous chemicals.

History of Medicine in Minnesota

A MEDICAL HISTORY OF MEEKER COUNTY PRIOR TO 1900

HAROLD E. WILMOT, M.D.

Litchfield, Minnesota

(Continued from April issue)

A Dr. Mumsford, Kimball, Minnesota, signed a death certificate for a patient in Meeker county. This was the first filed record in our present court house.

Dr. Boeckman.—We also find Dr. Boeckman of Saint Paul signing death certificates in 1889 and 1890. I believe it was common to have a consultant such as Dr. Boeckman, or some other prominent physician from the Twin Cities, come to the bedside and assist in care of the case, and, if exodus occurred, he would sign the death certificate.

Dr. Carrol C. Carpenter.—There seems to be a difference of opinion about this doctor. Some thought he had no more license than that of a chiropractor.

In the Minnesota Medical Transcripts four men were licensed as follows:

Albert J.	December 31, 1883	George W.	November 22, 1884
George A.	April 20, 1885	T. S.	January 8, 1885

Inasmuch as we see no C. C. Carpenter listed as a practitioner before 1900, and again inasmuch as Dr. C. C. Carpenter came to our community in 1890, we are compelled to believe that he was not a regular practitioner.

One of our personal acquaintances has already stated that he was probably not a regular practitioner. Another of our close friends of the older school has stated that in his opinion he was of the chiropractic school, and that his wife left him and they were divorced.

He had an upstairs office and was of quite professional appearance. However, he didn't do very well and went to Minneapolis, but probably returned to Litchfield again after 1900.

News Ledger, October 21, 1914—(An Announcement). "To correct what seems to be a general opinion that I am limiting my practice to some specialty, I wish to make the following statement: I am a graduate of the Minnesota Medical College of 1897; and after being in general practice for ten years, I took four months of resident hospital work in surgery and obstetrics and again resumed general practice today.—Dr. C. C. Carpenter, Litchfield, Minn."

The Old Settler states: "Because of baby cases, he was run out of town."

Dr. Henry E. Cassel.—In the *Dassel News,* January 31, 1888: "Dassel has a new doctor, one Cassel by name, but of his efficiency we know nothing." On July 12, 1888: "Dr. Cassel has located in Cokato."

After moving to Cokato he made weekly visits to Dassel. His address given on a death certificate filed in 1889 was Cokato. He moved to Litchfield apparently in

the early spring of 1899. His professional card first appeared in the *Independent,* April 11, 1899, and read as follows:

"Dr. Cassel
Scandinavian Physician and Surgeon
Calls answered promptly day or night
Office over Johnson, Larson and Wanvig's store
Will be absent in the East until May 5th"

Independent, April 18, 1899—"Dr. Cassel left Wednesday for New York to be gone until May 5. He goes to get pointers on anything that is new in the practice of medicine."

Independent, May 15, 1888—"He was elected to be county Democratic delegate to the State Democratic Convention."

Independent, December 28, 1897—"Dr. Cassel is making no progress toward recovering from his mental troubles according to advices received from the Fergus Falls Hospital. He is continually writing letters, and these show plainly his unsoundness of mind."

Rumor has it that his medical difficulties were caused by grief over being refused in marriage. He did, however, recover apparently completely, as he became a very active and famous surgeon during the next decade in Litchfield. Many times he was called in to the Swedish Hospital in Minneapolis to do or assist in doing surgery of very complicated type for the times, sometimes being accompanied by Dr. Karl A. Danielson, residing in Litchfield as his assistant.

Dr. Danielson states that Dr. Cassel was educated in his native country of Sweden, where he had mingled with the aristocracy and nobility and spoke the Swedish language perfectly. He was very popular in the community because of his exceptional ability, as there were other personal characteristics of a derogatory nature.

He weighed well over three hundred pounds, and as a gourmet, glutton, and connoisseur of brandy had no rival other than perhaps the famous Henry VIII of England. He, however, unlike Henry, was only married once; his wife was a Scandinavian nurse from Kingston or Dassel, and she survived him one year, meeting a tragic death when her clothes became saturated with gasoline and were ignited, presumably by herself. She was buried in Ripley cemetery, Litchfield, December 12, 1912.

Many are the tales told of him; due to his enormous size and ready wit and sarcasm, he no doubt will be the outstanding personality in Meeker county's medical history. He employed a driver always, in the horse and buggy days, and many times had to have an entire seat to himself. What a figure this must have presented to the populace! When the automobile came in, he was one of the pioneer owners; and as the steering bar in those days took the place of the present wheel, he had to sit on the opposite side, for there wasn't room for him between the bar and the back of the seat. At one time he overshot a corner in this automobile and it turned over, tipping him on his back in a marsh. He could not extricate himself alone, but soon a passerby assisted him out. He used his characteristic pharse in greeting the helper, "Kristamighty, would you see me drown?"

Another time, while drinking Three Star Hennessey and "Appolinaris Water" after hours with a close friend in the back room of a drug store, the friend, in the hope of getting some free medical advice, kept plying him with the brandy. His keenness being unaffected, he remarked, "Kristamighty, are you trying to drink the doctor drunk?"

When in a grocery store one evening making some purchases, a man approached

him and showed him an infected finger and asked, "What shall I do about this?" His reply: "Vell, I should see a good doctor."

It has been reported that if he had a particularly difficult surgery to do, he did much better by fortifying himself with a half tumbler of brandy just beforehand.

One time in a group of men, one asked him, "Doc, just how much do you weigh?" His answer: "Kristamighty, are you a cattle buyer?"

In the A.M.A. Register of 1884 his name is listed Cassel, Karl H. E., now called Dr. Henry E. Cassel formerly Karl Henry E. *Castle.*

He graduated from the University of Minnesota as M.D. in 1883 and carried Minnesota License No. 597, dated December 31, 1883, by exemption. The Registry further reported that he was licensed in Illinois in 1881; that he was a member of the A.M.A. and director and chief surgeon of the Litchfield Hospital in 1911; and that he died of septicemia due to a needle wound inflicted while doing surgery.

Litchfield Independent, April 4, 1911—"Dr. H. E. Cassel succumbed to blood poisoning at Luther Hospital, St. Cloud, April 4, where he was a patient for the past week. The infection was caused by a slight prick on a finger from one of his surgical instruments about three weeks ago. He would have been fifty-one years old in August."

The burial notes of the Ripley cemetery, Litchfield, show that he was buried there April 7, 1911, and the cause of death given as diabetes.

Dr. Warren B. Robb.—About May 1, 1889, Dr. Robb entered his professional card in the Litchfield papers. He carried the title M.D. and had his office over W. W. Johnson's drug store. He had previously practiced at Long Branch, Minnesota. He was listed in the Official Registry of Physicians of Minnesota as follows: "License No. 816—W. B. Robb—R—2-22-1884—graduated from the College of the City of New York in 1883." His address at the time he received his certificate was Litchfield, but he was a member of the Ramsey county Medical Society October 27, 1884. He joined the M.M.A. in 1885. He was on the registry of St. Joseph's Hospital, Saint Paul, in 1885. Polk's Medical Directory lists him in Saint Paul in 1886 but not in 1890.

Just when he left Litchfield and moved to Grove City, I am unable to ascertain. He signed death certificates in the county in every year consecutively from and including 1891 through 1897 from Grove City. A few notes of his attendance to patients are seen in the Grove City items in the later '90's, and a note of February 11, 1897: "Dr. Robb of Grove City was in our town yesterday, and he says the road from here to the other town is out-o-sight most of the time." He was listed in Grove City in 1898 and 1900.

About that time, according to recollection of a friend of mine from Grove City, he became ill and they "took him away." His wife was from Saint Paul, and they were married before coming to Meeker county. He was a big gruff fellow with red hair and whiskers and of very aristocratic appearance, was a member of the Episcopal church, and had a fair practice.

Another old settler tells me that the doctor was in Grove City as late as 1900, that about that time they took him to the University Hospital, that he had been acting queer, and that they found he had a brain tumor, and that he "died of it."

Dr. James W. Robertson.—Probably our most illustrious and successful physician to date was Dr. Robertson. He is stated to have come to Litchfield in 1891, but I find a notation in the *Independent* of May 7, 1889, wherein he cared for a patient.

He was born at Perrysburg, Ohio, July 26, 1852. He was educated in public high schools of that city and the University of Michigan. He then entered the Detroit Medical College and graduated with the class of 1877. He then took special courses at Vienna, Edinburgh, and Paris, and returned to become lecturer on laryngology in the Detroit Medical College and professor of obstetrics in the Michigan Medical College for the next ten years. He was on the staff of St. Mary's, Harper, St. Luke's, and Providence Hospitals there. He also served as chief surgeon of the Lake Shore Railway for several years.

When he located in Litchfield, he was a member of the A.M.A. and became a member of the Minnesota Medical Association of which he was elected president in 1911. He was an early member and secretary of the Crow River Medical Society and served as Litchfield's Great Northern Railway surgeon for years. He was a fellow of the American Laryngological Association and had been secretary of the Detroit Academy of Medicine and the Detroit Medical Library Asssociation. He was mayor of Litchfield and a member of the Board of Health and the Board of Education.

He read several papers before the Crow River Valley Medical Society on advances in medical practice of that time. The subject matter was perinephritic abscess in one, and he brought out the occasion of pain when a galvanic current was passed over the abscess and described operating a case under local novocaine anesthesia.

Another case of excision of the rectum for cancer was described, in which Drs. Archibald and Bissel assisted him.

He discussed the use of glycerinated vaccine for smallpox vaccinations and smallpox itself, which was timely then (1901), as an epidemic was in progress throughout the state.

Dr. Robertson developed a large and lucrative practice at once on arrival in Litchfield. He was married previously, September 17, 1872, to Miss Ella J. Phelps. His wife and the doctor himself had relatives among the early pioneers of Litchfield and this may have helped to induce him to come to Litchfield. He erected a large brick building of two stories about seventy-five feet square in conjunction with a pharmacist named Lundemo about 1912, and had a spacious suite of offices on the second floor, with a terrazzo floored operating room and hospital rooms. An elevator was also provided and all modern facilities of the day.

Dr. Robertson was a large strong, ruddy complexioned, sandy haired, blue eyed typical Scot. He was terrifically energetic, fair minded and possessed of a "quick temper." He was much respected by his colleagues and a sterling worker for the advance of medical facilities for the community. In the new Meeker County Memorial Hospital, a room has been furnished in his name, with a suitable plaque on the door, by Dr. George W. Sherwood of Kimball, Minnesota.

Dr. Robertson had three sons—Archibald W., William, and Carl T.—all of whom became physicians, Archie and William returning and practicing in the original building until their early and untimely deaths by coronary disease. Carl served as captain in the Navy as an E.E.N.T. specialist until his death at an early age from the same cause. Four grandsons are living and carrying on the Robertson traditions.

Dr. James W. Robertson died August 13, 1913, following an operation for ruptured appendix and was buried in Ripley cemetery, Litchfield, Minnesota, August 15, 1913.

Dr. John Vincent O'Conner.—Dr. O'Conner practiced in Watkins in the second half of the 1890's apparently only a short time, because in 1898 he is listed in

Waverly Mills, Wright county. It seems he did not leave much of an imprint in Meeker county. In 1900, too, he is listed in Waverly Mills where he supposedly practiced for four years. From Wright county he moved to Saint Paul where he built up a successful practice.

Dr. O'Conner was born on September 1st, 1867. He was an accomplished pianist in Minneapolis and earned the means for his medical education by teaching music. He graduated from the Medical Department of the University of Minnesota in 1895, and was licensed in the same year. Dr. O'Conner died in Saint Paul on April 5, 1932.

Dr. George E. Sherwood.—Born February 14, 1872, Dr. George E. Sherwood, regular, has practiced his profession in Kimball, Minnesota, since October 15, 1900.

Dr. Sherwood's parents were George W. Sherwood and Adeline Hard, who came to St. Paul in 1855. George W. Sherwood was widely known for his trotting horses bred at Sheldon, Iowa. Dr. Sherwood's grandfather was Willam Sherwood, a sea captain in the American Navy during the War of 1812. His grandmother was Jane Bogardus, a descendent of Annese Jans Bogardus, a Hollander who owned a farm on Manhattan Island where historic Trinity Church now stands.

Dr. Sherwood graduated from the Saint Paul High School in 1890 and from the University of Minnesota Medical School with honors in 1894, and received his Minnesota license July 10, 1894. He was one of the first interns at Saint Joseph's Hospital in Saint Paul. In the fall of that year he located at Dassel, Minnesota. He was ambitious and enjoyed a lucrative practice.

In 1898 he purchased a two-story brick building with full basement and installed an early type x-ray machine, one of the first in the county. He added other equipment, employed two nurses and had hospital rooms; and while his major cases were operated in larger hospitals, this might well be called one of the first hospitals in Meeker county, for anesthesia and after-care were available.

On January 12, 1898, Dr. Sherwood was married to Miss Mary E. Milton of Howard Lake, Minnesota. Mrs. Sherwood died of cerebral malacia in 1955. To this union were born three daughters—Jane (Mrs. Orville Nelson, whose husband is an E.E.N.T. specialist), St. Petersburg, Florida; Helen (Mrs. Ed Lax), and Ruth (Mrs. Kenneth Lewis, Detroit, Michigan). A son, George, died of pneumonia in childhood.

While in Dassel Dr. Sherwood was elected president of the city council and was one of the charter members of the Crow River Medical Society. He was a member of the Dassel Board of Education and belonged to the Knights of Phythias, Modern Woodmen, Royal Neighbors, and was active in prohibition circles. He is an ardent nimrod, amateur photographer, gardener, and has for years been interested in purebred Guernsey cattle on his several farms.

He has consistently been a member of the A.M.A., the M.M.A., and the Stearns-Benton Counties Societies, being three times president of the latter. He is a past president of the Northern Minnesota Medical Association. He is at present a member of the Christian Church, Masonic Lodge, and Eastern Star of Kimball and has been president of the State Bank of Kimball.

In 1928 he attended the International Dairy Congress in London on the appointment of President Coolidge, and at that time visited nine European countries. He revisited Vienna in 1930 for postgraduate work. He took an air tour of South America, visiting seven countries, in 1949 and has been perennially in Mexico

1. Unpublished medical history of Wright county by Dr. J. J. Catlin and R. Rosenthal and Obituary in *Minnesota Medicine,* May 1932, page 344.

City and St. Petersburg, Florida, for the past ten winters. In 1955 he again made a pleasure tour of Europe. He has taken extensive motion pictures on these tours which have been greatly enjoyed at medical meetings and throughout his community.

His practice extends well into our county and Stearns county, and he is a member of the staffs of the Meeker county Memorial and St. Cloud hospitals.

Dr. Sherwood is a high principled, industrious, congenial fellow, ever ready to help a good cause, and enjoys the utmost respect and admiration of his fellow doctors and the people of his community.

In 1944 he received the medal for fifty years of practice from the Minnesota Medical Association, together with its well deserved accolades.

He is a linguist of no mean ability, understanding the Swedish and Norwegian terms, speaking French, speaking and reading German well, and being really fluent in Spanish. He is tall, erect, lean and well preserved, enjoying life as much as always.

Dr. Frank M. Archibald, regular, Atwater, Minnesota, apparently came to Atwater for at least part time about 1900, for we find that he read a paper, "Disease of the Tonsils and Their Treatment," before the Crow River Valley Medical Society meeting at Dassel, February 6, 1900. His signature also appeared on a death report in 1898.

His practice extended well into the western portion of Meeker county, and he was a dynamic force in the local progress of medicine. He was known to be ever ready to respond when his services were required. Standing about six feet and weighing in excess of three hundred pounds and inately kind to man and animal, he was affectionately known throughout Kandiyohi and Meeker counties at this time and in 1906 became Mahnomen's first physician, remaining there until his death on March 3, 1936, from cerebral hemorrhage and a fractured leg suffered sixteen days before.

Born December 6, 1865 at Lindenwood, Ogle county, Illinois, he attended local schools and the preparatory school in Dixon, Illinois. He graduated from the Medical College of the University of Illinois in 1893, and married Miss Josephine W. Baily, who died in 1927. A son, Frank, lived in Fargo, North Dakota, and a daughter, Adelaide, in Mahnomen. Further details may be found in Kandiyohi county's medical history.

Dr. Gustav C. Vibrance.—Apparently Dr. Vibrance came to Watkins about 1898, as a death certificate filed in the court house that year bears his signature.

He graduated from the University of Minnesota, year not known, and was licensed in Minnesota April 10, 1900, Certificate No. 1148. His card lists him as deceased but does not say when or where. Apparently he was not a member of the Minnesota Medical Association.

I was advised by Dr. Sherwood that Dr. Vibrance had relatives in Minneapolis and that he was one of the first doctors in Watkins. He states that he died about 1902, but whether before or after he left Watkins, Dr. Sherwood did not know.

Mr. N. H. Ley of Watkins stated that Dr. Vilbrance had two daughters, Viola, married to Lou May in Duluth, and Lillian, married to a Nelson in Minneapolis. Mrs. May did not answer correspondence, and a Nelson in Minneapolis seems futile to search. He further states that he came to Watkins in about 1903 and died at age forty in 1905 at Watkins.

He was listed in Polk's Medical Directory as August Vibrance in Watkins in

1898, and may have been doing "locum tenens" work before finishing his college work.

The following men signed death certificates, practiced in Meeker county a short time, or were mentioned in news items:

Dr. Hoover of Paynesville treated a patient with an infected hand in Manannah in 1884.

Dr. Rollin Cutts, Professor of Surgery at the University of Minnesota later, gave the high school class prophecy at graduation in Litchfield High School in 1885.

Dr. Hillson has "leased the Cochran (or Morris) residence and will carry on his medical practice here again this season."

"**Dr. Carter** of Minneapolis was in Dassel last week paying his monthly visit. He has good business in his chosen calling."—1888.

"**Dr. Wakefield** was in Litchfield examining applicants for pension, together with Dr. Bissel."—August 20, 1889.

Dr. Boeckman of Saint Paul signed death reports 1889 and 1890.

Dr. Lewis R. Fernald of Bellingham and Appleton attended patients in Litchfield. In 1890 he retained Minnesota License No. 165, dated October 15, 1883; and he was a graduate of Albany Medical College in 1875.

"**Dr. J. W. Shaw,** M.D., pulled stakes from Grove City last Friday and went to Minneapolis where he intends to spend the winter. Grove City is again without a doctor and the 'bachelor's hall' is not complete. He stayed only a little more than a month."—1885.

Dr. W. Smalley of Hector attended a sick person in Cosmos in 1889 and also signed a death certificate in 1896.

April 14, 1887: "**Dr. W. E. Aubin,** formerly of Perham has located in this city (Litchfield) and for the present offices at the Howard House. After May 1st he expects to occupy rooms over Wakefield Store. He is a pleasant gentleman and comes well recommended as a physician." The *Perham Bulletin* states the same and that he was at one time a well-to-do physician there and had been there five years. Owing to a sickness in his family, he went to Litchfield. He came from Canada originally.

Dr. Chalmers (or Calmer) of Paynesville signed death reports in 1894 and 1896.

Dr. W. A. Burns of Hector signed a death certificate in 1896.

Dr. G. P. Ferrell of Paynesville did likewise in 1896 and 1899.

Dr. Proesch of Fair Haven also signed death reports in 1889, 1891, and 1898, and was mentioned in Watkins and Eden Valley at that time.

Dr. W. H. Aborn was mentioned in Eden Valley at about 1890.

Dr. Monker, Fairhaven, previously mentioned in 1892 and 1893.

Dr. Sagelin of Hutchinson signed a Meeker county death report in 1893; **Dr. Arnold,** Cold Spring, did the same for 1896; and **Dr. Francis Illstrup,** Cokato, likewise for 1894 and 1895. **Dr. L. S. Schroeder** of Cedar Mills signed a death report for 1896.

Dr. Alfred M. Ridgeway of Annandale signed reports in 1896 and was mentioned as locating in Eden Valley May 9, 1899, but evidently did not remain long. He returned later to Annandale. He also was a member of the "50 Years' of Practice Club." The following is the obituary of Alfred Miller Ridgeway appearing in the June, 1952, issue of MINNESOTA MEDICINE.

"Dr. Alfred M. Ridgeway, a practicing physician in Annandale for over sixty years, passed away May 19, 1952, at the age of ninety.

"Dr. Ridgeway was born in Columbus, Wisconsin, January 29, 1863. In 1882 he came to Minneapolis and was employed in a drug store until 1887, when he entered the medical department of the University of Minnesota. He was graduated in 1890 and was the only intern at the Minneapolis City Hospital before opening an office at Annandale in July, 1890. He took postgraduate study in Chicago in 1895 and again in 1900.

"Dr. Ridgeway helped organize the Wright County Medical Society some sixty years ago. He was a member of the Minnesota State Medical Association and the American Medical Association. He was also a member of the American Association of Railroad Surgeons and had been a surgeon for the Soo Line since December, 1909. He was a charter members of the I.O.O.F. and Rebecca lodges of Annandale and a member of the A.F. and A.M. lodge. He served in the Village Council and was mayor of Annandale in previous years.

"In July, 1940, Dr. Ridgeway's many friends took part in a celebration of fifty years of practice by the physician. Many of those who participated were of the 3,500 brought into the world by Dr. Ridgeway.

"On September 20, 1892, Dr. Ridgeway married Miss Nola Ponsford. She survives him. Although they had no children, they provided a home for many young girls and helped them complete their education." It was my privilege to know this energetic, alert, ruddy-faced man with his close clipped crisp gray mustache and good humor was bubbling—his job was ever well done.

Dr. Croke of Hutchinson signed a death certificate in our county in 1897.

A Dr. A. Anderson in August of 1898 inserted a professional card in a Litchfield paper as a "Scandinavian Physician and Surgeon." In another column it was stated that Dr. Anderson of Minneapolis had made arrangements to locate in Litchfield. I cannot believe that this is the D. Andrew E. Anderson of Minneapolis who helped establish the Swedish Hospital in Minneapolis, but it is possible. No further mention is made in Litchfield.

Dr. George S. Putney of Paynesville also signed a death report in Meeker county in 1899.

Dr. Charles Bolsta practiced a few months in Grove City. He was licensed in Minnesota in 1895 and graduated from Rush in the same year. He was reported in Ortonville from 1895 until as late as 1950. He was described as being "heavy set and dark" by a Grove City resident.

Dr. Nels A. Biorn practiced a short time in Grove City in 1899. He was a student at Hamline College at the time (Minnesota Medical College) and in 1901 graduated and settled in Ada, Minnesota. His son, Rev. Richard Biorn, lives at Northfield.

Dr. Hand (probably **Dr. William R. Hand**) of St. Paul attended patients in consultation with Dr. Chapman and signed death certificates in this county in 1889 and 1899. He graduated (if this be the one) from Cincinatti Physicians and Surgeons College in 1877, was licensed in Minnesota February 18, 1884, License No. 811. He was born in Hawley, Pennsylvania, September 14, 1856. He practiced in Herman, Kasota, and eventually Elbow Lake, where he remained until his retirement in 1936 after sixty years of practice. He died May, 1939, at the age of eighty-two years in Fargo, North Dakota, from "myocarditis, gallstones, and common duct obstruction."

Dr. William E. Tryon, Dassel, "Located in our village in 1900 and was here three years, then left for Minneapolis where he had a good practice till his death in that city." Dr. Tryon was a graduate of the Bennett Eclectic Medical College of 1885. He held Minnesota License No. 1036, dated April 20, 1885. He was listed in 1890, Minneapolis; and 1895 and 1898, Austin; 1903 and 1905, Dassel; and 1909, Minneapolis. He died March 5, 1927, at the age of seventy of coronary sclerosis and diabetes.

We must include a druggist, **Virgil H. Harris,** born in Newark, Ohio, May 14, 1840, and died in Litchfield October 18, 1910. He served in the 111th Ohio

Regiment in the Civil War for three years. He settled in Litchfield in 1870. He was the author of a book. *A Trip Through Hell—An Epic of the Unseen* (a story of the Civil War). He was probate judge for many years; and his son, E. V. Harris, succeeded to the same bench for one term. Inasmuch as some of the stories concerning Dr. Cassel emanated from E. V. Harris personally to me, I cannot but feel that our good judge and pharmacist, Virgil H. Harris, and Dr. Henry E. Cassel spent some convivial evenings in his drug store.

Hospitals.—As previously mentioned. Dr. Sherwood had a few hospital rooms in Dassel in 1898.

The first authentic hospital was operated by a Mrs. Leroy, R.N., in Litchfield, Minnesota, January 1, 1897. Pressures by Drs. Cassel, Chapman, and Robertson with their local confreres were no doubt instrumental in building up this establishment. This continued to be in active use for ten years after the turn of the century, when, as previously noted, Dr. Robertson built his own hospital.

In later years other hospitals followed. Finally in 1952 the present Meeker County Memorial Hospital was built.

* * *

These are the men and women we record as being active in the pioneer days of medical practice in Meeker county. It will be noted then, as now, that men of this profession move about frequently, due to various circumstances, until the currents and eddies of life's river bring them to a tranquil spot. Regular itinerant visits at intervals in smaller towns were more common in those days, and served well the communities, as well as establishing the individual doctor more firmly.

May we appreciate their conscientious efforts amidst those trying days and profit thereby.

Acknowledgment

This has been a cooperative effort to give to the Minnesota State Medical Association the best information we have available concerning the medical care and the doctors of Meeker County from the inception of the county until the year of 1900.

We are indebted to the following:

1. *A Random Historical Sketch of Meeker County, Minnesota,* by A. C. Smith, President of the Bar and Old Settlers Association and said county; Published by Belfoy and Joubert of Litchfield, Minnesota, in 1877; Prepared as an observance of our one hundredth year of independence on the advice of our beloved President, U. S. Grant, and ordered by Hamilton Fish, Secretary of State.
2. *The Album of History and Biography of Meeker County, Minnesota;* Published by Alden Ogle and Company, Chicago, 1888.
3. *Municipal Progress,* 1899.
4. *Those Were the Days.* Published by O. E. Linquist of the *Dassel Dispatch* in 1941.
5. *Condensed History of Meeker County, 1855-1939.* Compiled and published by Frank B. Lamson, Litchfield, and the Brown Printing Company, Litchfield.

We are further indebted to the publishers and owners of the *Litchfield Independent* ("Free and Unshackled"), *The Litchfield Review, The Litchfield News Ledger, The Ledger,* and the *Meeker County News.* There are clippings from other Meeker County papers to which we are also indebted. Most of the quotations will be found in these earlier publications.

6. The Minnesota Historical Society and the A.M.A. have as usual contributed their share.

Perhaps the most valuable personal contributions have been made by Dr. K. A. Danielson, members of the Meeker County Old Settlers' Association, and various friends throughout the county who have searched their memories and their family archives to aid in the accuracy of our records.

Naturally, our chairman, Dr. Robert Rosenthal, with his enthusiasm and ready access to medical records, has been of inestimable help in this effort.

Committee Action

BOARD OF EDITORS
MINNESOTA MEDICINE

Alternations in Format
Gain in Advertising
Section on Public Relations
Increase in Cash Surplus

To the House of Delegates of the
Minnesota State Medical Association:

In addition to the routine activities of the Board of Editors during 1958, the principal efforts of this group at its five meetings during the year pertained primarily to a program of modernization of MINNESOTA MEDICINE. Progress along these lines had been slow during previous years. It was greatly augmented through a combined meeting of the Council, and the Board of Editors to hear Mr. O. M. Forkert of Chicago on December 14, 1957. The drastic alterations in the cover page, format of headings, blurbs, and page proof make-up did not begin bearing fruit until the end of the year.

A report after the first ten months of 1958 from the State Medical Journal Advertising Bureau revealed that MINNESOTA MEDICINE had a gain over 1957 of 40.2 per cent in advertisements obtained by the S.M.J.A.B. The average gain shown by the thirty-three Journals sold by S.M.J.A.B., during this period, was 23.9 per cent, and the highest other than MINNESOTA MEDICINE was a 29 per cent gain. According to Alfred Jackson, "this is fabulous since no other medical journal can report the increase outlined above." I attribute this gain primarily to the many physicians of Minnesota who have published scientific manuscripts of outstanding quality in our State Journal. A combination of this excellent record of advances in medical science with a most pleasing, inviting and acceptable style of publication should improve the national reputation of the Journal.

The cooperation of the various medical specialty organizations of the state has resulted in a selection of manuscripts presented at the meetings of these societies and has made procurement a matter of simple routine. The authors of outstanding scientific articles in out-of-state medical journals have proved an important and dependable source of editorials for our Journal. From the viewpoint of quantity and quality of scientific manuscripts, MINNESOTA MEDICINE could be published biweekly without difficulty.

After years of attempting to do so, it was possible to initiate a Section on Public Relations written and edited by Mr. Carl Woyke. Our Section on Committee Action—representing business and scientific activities of our organizations has faltered through the year, but needs the same intelligent and enthusiastic editorship shown by Mr. Woyke in his section of the Journal. Reports are that physicians throughout the State are very much interested in the activities of the Council and various committees of the society, even if these are simply stated in subject form where more detail does not seem desirable.

Several efforts at promoting and developing a Section on "Clinical Briefs" seemed by the end of 1958 to be headed for failure. The outstanding demand of the membership in the poll on MINNESOTA MEDICINE taken at the last State Medical Association meeting in Rochester was for regularly appearing, brief summarizations of applied medicine. To this end, the Board of Editors have initiated a new approach to the matter, hoping to utilize various state specialty societies for the responsibility of procurement.

Besides a slow failure in the section on "Clinical Briefs," there was a serious paucity of scientific manuscripts in the field of pediatrics, anesthesiology, proctology, and otolaryngology in the volume of 1958. Steps have been taken toward overcoming some of these defects.

The perpetually late publication of MINNESOTA MEDICINE (after the 10th of the month) has shown no improvement during 1958, but the Bruce Publishing Company has now assured us that a new schedule, effective immediately, will correct the situation so that the Journal will be printed by the 10th of the month.

It should be noted that MINNESOTA MEDICINE doubled the cash surplus of 1957, and it has increased roughly four or five times during the last five years, from about $3,000.00 to $15,000.00. This is in spite of the fact that the membership is being charged only $3.00 or half of the usual cost of a Journal of this scientific stature.

The Board of Editors hope to promote, either alone or with the aid of others, a larger circulation particularly among the physicians in the adjoining states and provinces in the near future.

A. H. WELLS, M.D.
Editor

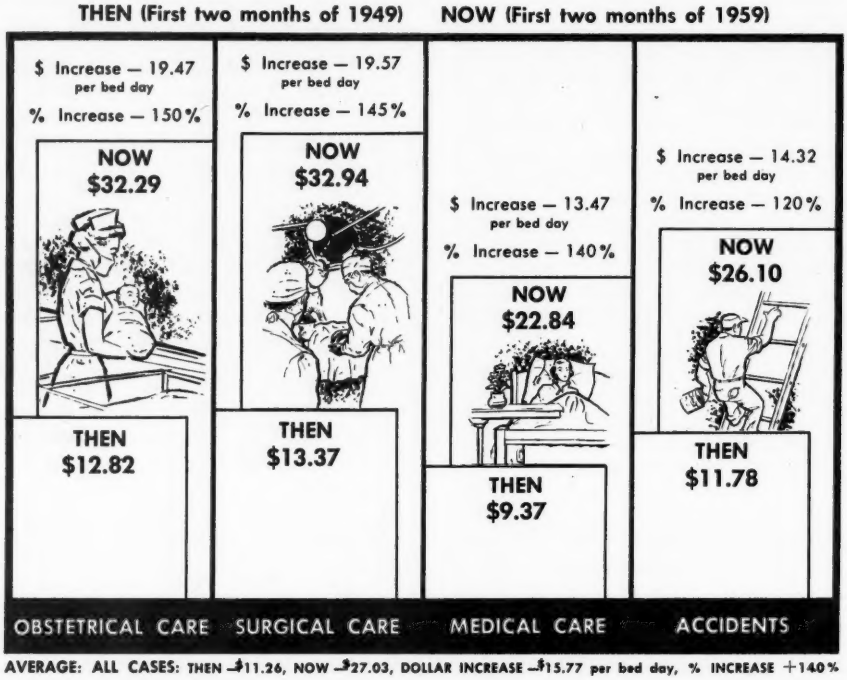
Minnesota Blue Shield-Blue Cross

Minnesota Blue Shield participant subscribers numbered 890,023 as of March 31, 1959. Of this number 107,164 were Plan B subscribers and 782,-859 were enrolled under Plan A contracts.

As of the same date last year, Blue Shield enrollment consisted of 82,880 Plan B subscribers and 788,994 Plan A subscribers or a total of 871,874 persons.

During the twelve months between March 31, 1958, and March 31, 1959, the number of Plan B subscribers increased 24,284 while the total number of Blue Shield subscribers increased only 18,-149. Plan B subscribers represented 12 per cent of the total number of persons enrolled as of March 31, 1959, and the increased Plan B enrollment indicates that a greater number of Minnesotans are willing to pay the additional cost of the higher benefit contract.

Physicians' services eligible for Blue Shield benefits under the two plans are identical, but Blue Shield allowances and the cost to subscribers are greater under Plan B than under Plan A.



The Blue Shield financial report for the first three months of this year shows that doctors were paid $2,513,886 for 92,930 services rendered subscribers. Blue Shield payments in this period exceeded by $127,629 the amount paid in the same period of last year and allowances were provided for 7,013 more doctors' services than were paid by the Plan in the first three months of 1958.

The accompanying chart shows a ten-year comparison of average Blue Cross benefits per bed-patient day provided in the areas of obstetrical, surgical, medical and accident cases. (January and February, 1949, average compared to January and February, 1959, average.) As can be noted, the average allowance increase of all four categories amounted to 140 per cent.

From the standpoint of benefits paid per patient day, during the first two months of 1949, Blue Cross allowances represented 68.7 per cent of hospital charges. During the same period in 1959, Blue Cross provided allowances equivalent to 80.9 per cent of hospital charges.

INCREASE IN VALUE OF BLUE CROSS COVERAGE

(In terms of Blue Cross allowances per bed patient day)

AVERAGE: ALL CASES: THEN —$11.26, NOW —$27.03, DOLLAR INCREASE —$15.77 per bed day, % INCREASE +140%

Underweight Children Gain and Retain Weight with Nilevar®

One of the most convincing evidences of the anabolic activity of Nilevar, brand of norethandrolone, has been its ability to improve appetite and increase weight in poorly nourished, underweight children.

A highly important feature of the weight gain thus produced is that it is not ordinarily manifested by deposition of fat but as muscle tissue resulting from the protein anabolism induced by Nilevar.

Anorexia and "Weight Lag" Study—Brown, Libo and Nussbaum have reported* consistent and definite increases in rate of weight gain in eighty-six patients, ranging in age from 7 weeks to 15½ years. This beneficial action of Nilevar was observed in the patients with organic and traumatic disorders as well as those whose only complaints were poor appetite and/or persistent failure to gain weight.

In this study, the weight gained was not lost after discontinuance of Nilevar therapy although many patients did not continue the sharp gains effected by the drug.

The authors are of the opinion that Nilevar is a highly useful anabolic agent for influencing weight gain in underweight children.

When Nilevar is administered to children a dose of 0.25 mg. per pound of body weight is recommended and continuous dosage for more than three months is not recommended.

Nilevar is supplied as tablets of 10 mg., drops of 0.25 mg. per drop and ampuls of 25 mg. in 1 cc. of sesame oil. Further dosage information in Searle Reference Manual No. 4.

Woman's Auxiliary

THIRTY-SEVENTH ANNUAL STATE MEETING REVIEWED

The thirty-seventh annual meeting of the Woman's Auxiliary to the Minnesota State Medical Association was held May 26 at the Hotel Duluth.

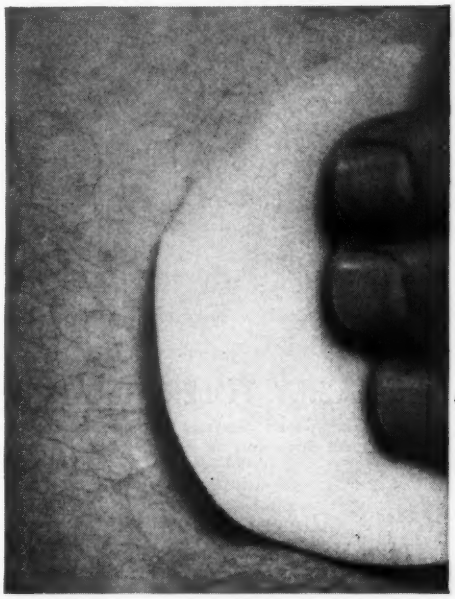
The meeting was called to order by the president, Mrs. Reuben F. Erickson, and a warm welcome was extended to all the visiting women by Mrs. Gordon J. Strewler, president of the hostess auxiliary, St. Louis County.

Mrs. A. M. Jensen, Brownton, conducted a most impressive "In Memoriam" service. As the name of each deceased member was read, a rose was presented in her memory. Violin music which accompanied the ceremony was provided by Mrs. A. C. Hilding, Duluth.

The reports of the county presidents and state committee chairmen were read.

The following officers were elected for the ensuing year: President-elect, Mrs. Walter P. Gardner, St. Paul; First Vice President, Mrs. Wallace A. Merritt, Rochester; Second Vice President, Mrs. Harold Benjamin, Minneapolis; Third Vice President, Mrs. William Gjerde, Lake City; Fourth Vice President, Mrs. Benjamin B. Souster, St. Paul; Recording Secretary, Mrs. Milton M. Howell, Glencoe; Treasurer, Mrs. Elmer M. Hill, Minneapolis; Auditor, Mrs. Fred Westerman, Montgomery; Historian, Mrs. John Dordal, Sacred Heart, and Parliamentarian, Mrs. Leo Fink, Minneapolis.

Mrs. Reuben Erickson gave her report capsulizing a year of exhaustive residential activities.



The meeting was adjourned and the Annual Luncheon followed in the Ballroom of the Hotel. The luncheon tables were decorated with garden boxes of assorted pink and white petunias, and favors for everybody.

Two highlights of the luncheon were the presentation and installation of the new president, Mrs. M. F. Fellows, Duluth, by Mrs. H. E. Bakkila, also from Duluth. The installation of the other new officers was done by Mrs. C. L. Oppegaard, Crookston. In relinquishing her office of president to her successor, Mrs. Erickson pinned a rose to the gavel signifying her continued love and devotion for the auxiliary.

A special guest throughout the convention was Mrs. William Mackersie, Detroit, Michigan, Regional Advisor. The women were privileged to hear her very inspirational address on the topic "Wheels of Progress." Mrs. Mackersie reviewed all the standing committees on the state level and concluded by comparing the structure of the auxiliary to that of the wheel: The hub being composed of the state officers and committee chairmen; the spokes comprising the county officers and boards, and the rim representing the membership as a whole. She pointed out that the impact of the wheel in motion is felt most acutely on the rim which in turn depends upon the spokes and hub for its strength.

Mr. E. R. Lambert, former Mayor of Duluth, spoke on the subject, "What the Seaway will mean to Minne-

sota." He described briefly a few of the myriad problems and blessings that attend this tremendous undertaking. Of special interest to the medical groups, he pointed out, was the introduction of new and strange disease germs to which this population has not heretofore been exposed, as well as the different breeds of rodents which accompany the ships and create a health problem as carriers of various disease germs. On the asset side, he predicted that Duluth will shortly become an international shopping center unique in this country, having bazaars and shops supplied directly from all points of the world.

Mr. Lambert's address was very enlightening as he enumerated advantage upon advantage as well as problem after problem—concomitant with the development of an international seaport within our state. The eventual meaning of the Seaway will depend upon the ability of the state as a whole to meet with vision and resourcefulness, the many challenges that will be presented, concluded Mr. Lambert.

Note of Thanks

The women of the State Auxiliary want to congratulate the St. Louis County Auxiliary on a beautifully planned and executed program during the convention. From flowers flown directly from Hawaii for the tables and corsages—for those who stood in the receiving line at the Tweed Art Gallery—to the hot coffee and rolls served each morning on the mezzanine—everything was appreciated and shall be warmly remembered. Co-chairmen in charge of all arrangements were Mesdames M. O. Wallace and I. T. Clark.

ST. LOUIS COUNTY ELECTS OFFICERS

Mrs. John E. Haavik was elected president of the auxiliary to the St. Louis County Medical Society at the annual luncheon recently in the Northland Country Club. Mrs. Haavik succeeds Mrs. Gordon J. Strewler.

Other officers chosen at the session include Mrs. F. W. Conley, president-elect; Mrs. J. B. Moyer, first vice president; Mrs. Richard Bardon, second vice president; Mrs. J. D. Barker, recording secretary; Mrs. C. D. Eklund, corresponding secretary; Mrs. V. R. Krueger, treasurer, and Mrs. H. J. Walder, assistant treasurer.

The on-the-job fatal accident rate ranks farming as the third most dangerous occupation. It is preceded only by mining and construction. There were 14,200 occupational deaths in 1955, and of these 3,700 (26 per cent) were connected with farms.

* * *

About thirty years ago, the usual patient entering the sanatorium with active tuberculosis was a young girl between fifteen and twenty-five years of age. At that time, female patients outnumbered male patients by a wide margin. Today the average patient entering the sanatorium is an elderly man.—*Christmas Seal Health News.*

In Memoriam

GORDON M. ERSKINE

Dr. Gordon M. Erskine of Grand Rapids died May 10, 1959 in Tucson, Arizona, of a lung ailment. He was fifty-nine years of age at the time of his death. His specialty was ophthalmology.

Dr. Erskine was a native of St. Paul and worked in the editorial departments of the *St. Paul Dispatch* and *Daily News* and *Minneapolis Tribune* prior to his graduation from the University of Minnesota Medical School. He practiced medicine in Grand Rapids from 1938 until 1957 when he retired for reasons of ill health.

Dr. Erskine was a member of the St. Louis and Range County Medical Societies, The Minnesota State Medical Association and the American Medical Association.

Survivors are his wife, Gleva; a son, Blain, student at Carleton College, Northfield; a sister, Mrs. E. B. Olwin, Maplewood, and a brother, Grant, of St. Paul.

RALPH K. GHORMLEY

Dr. Ralph K. Ghormley, former head of the section of orthopedic surgery of the Mayo Clinic, died June 6, 1959, of an acute attack of heart disease at Peninsula Community Hospital in Carmel, California. Doctor Ghormley was sixty-six years old.

Doctor and Mrs. Ghormley moved to Carmel a year ago after his retirement from the Clinic April 1, 1958. He was head of the orthopedic section of the Clinic from 1938 to 1955, and then became a senior consultant. Doctor Ghormley also served as president of the Clinic staff in 1952.

Doctor Ghormley was born in Portland, Oregon, February 10, 1893. He received the Degree of Bachelor of Science from Whitworth College in 1914 and Doctor of Medicine from Johns Hopkins University in 1918. From 1917 to 1919 he was a member of the Medical Corps of the American Expeditionary Forces in Europe, attaining the grade of captain and completing his military service at Letterman General Hospital in San Francisco.

In 1919 and 1920 he was an intern in Johns Hopkins Hospital and Children's Hospital School in Baltimore; in 1920 and 1921 was an intern in New York Hospital and in 1921 and 1922 was assistant resident surgeon in Johns Hopkins Hospital.

In 1922, Dr. Ghormley entered into the practice of orthopedic surgery with Doctor Robert W. Lovett in Boston, and in 1922 and 1923 he was an assistant in orthopedic surgery in Harvard Medical School. From 1923 to 1929, he was an instructor in that school, and was attending orthopedic surgeon to the Massachusetts General Hospital.

Doctor Ghormley came to Rochester in September 1929 as a consultant in orthopedic surgery of the Mayo Clinic and assistant professor of orthopedic surgery in the Mayo Foundation. He was advanced to the grade of associate professor in 1932 and to that of professor in 1937. In 1938 he was appointed head of the Section

of Orthopedic Surgery in the Mayo Clinic, a post he occupied until 1955, when he became a senior consultant. From 1933 to 1940 he served as secretary of the American Orthopaedic Association, and in 1948 and 1949 he was president of the organization. He was president of the Clinical Orthopaedic Society in 1941, and in 1951 and 1952 he was president of the American Board of Orthopaedic Surgery, Inc. He was elected president of the staff of the Mayo Clinic in 1952, and he served as president of the Mayo Foundation chapter of the Society of the Sigma Xi in 1943 and 1944.

Doctor Ghormley was a consultant in orthopedic surgery of the U. S. Veterans Administration. He has been a member of the advisory committee of the Children's Bureau of the U. S. Department of Labor. He was a fellow in the American College of Surgeons and a member of the American Medical Association, the Minnesota State Medical Association, the Zumbro Valley Medical Society, the American Surgical Association, the Clinical Society of Orthopaedic Surgery, the American Academy of Orthopaedic Surgeons, the Western Surgical Association, the American Association for the Surgery of Trauma, the Robert Jones Orthopaedic Society, the International Society of Orthopaedic Surgery and Traumatology, the Alpha Omega Alpha Medical honor society, the Society of the Sigma Xi, the Harvard Club of Boston and the Alumni Association of the Mayo Foundation. He was a corresponding member of the Scandinavian Orthopaedic Society.

In 1957, Doctor Ghormley was honored by former fellows in orthopedic surgery of the Mayo Foundation and his colleagues in the Mayo Clinic, in the form of establishment of the Ralph K. Ghormley Traveling Scholarship. This scholarship is designed to enable the recipients to visit the leading centers in orthopedic surgery in this country, and abroad for observation of the newest advances in the field.

Surviving Doctor Ghormley are his wife, the former Jean McDougal, Winnipeg, Canada, whom he married June 24, 1924; and two children, Lt. Ralph M. Ghormley of the U. S. Navy currently stationed at San Diego, California, and Mrs. Charles Baker of Rahway, New Jersey.

BERT E. HEMPSTEAD

Dr. Bert E. Hempstead, a member of the Mayo Clinic from 1921 to 1950, died April 15, 1959. He was seventy-five years of age at the time of his death.

Dr. Hempstead was a native of Bloomington, Illinois. He received his Bachelor of Arts Degree from Illinois Wesleyan University and his Doctor of Medicine Degree from the University of Michigan. His internship was served at the Northern Pacific Beneficial Association Hospital in Brainerd, Minnesota. In 1912, he went to Europe for graduate training and studied at the University of Vienna. He began his practice in 1913 in Duluth. From 1914-1918 he practiced in Miles City, Montana, before moving to Rochester.

He then joined the Mayo Clinic staff and was appointed an instructor in Otolaryngology and Rhinology in the Mayo Foundation Graduate School in the University of Minnesota. He was advanced to the position of Assistant Professor in 1923 and Associate Professor in 1931.

In 1925, Dr. Hempstead was certified as a specialist in diseases of the ear and throat by the American Board of Otolaryngology. He was a fellow of the American College of Surgeons, member of the American Medical Association, American Academy of Ophthalmology and Otolaryngology, American Laryngological, Rhinological, and Otological Society, American Otological Society, Alumni Association of the Mayo Foundation and the Society of the Sigma Xi. Dr. Hempstead was also a member of the former Olmstead, Houston, Fillmore and Dodge County Medical Society which now is the Zumbro Valley Medical Society.

Survivors are his wife, Millie; a daughter, Mrs. Samuel (Jane) Harper of Madison, Wis.; two sons, Dr. Richard of Spokane, Washington and John of San Francisco; five grandchildren, and four brothers, Earl and Robert of Bloomington, Illinois, Harry of Joliet, Illinois and Bernard of Los Angeles.

JOSEPH W. JESION

Dr. Joseph W. Jesion, former St. Paul physician, died April 29, 1959, in Veteran's Hospital in St. Cloud. He was seventy years of age at the time of his death.

Dr. Jesion, who had resided in St. Paul for 44 years, was associated with the Northern Pacific for thirty-nine years as a physician and surgeon before retiring in 1955. He had resided for a number of years in Pine River, Minnesota.

The deceased was born in Milwaukee, Wisconsin, and received his preliminary education at Marquette High School and St. Mary's College located at St. Mary's, Kansas. His medical education was obtained at Marquette University in Milwaukee, Wisconsin. He interned for one year at St. Mary's Hospital in Duluth.

He was a member of Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. In addition he was a member of Court Number 1487 of the Catholic Order of Foresters. He received the British Military Cross for his services with the U. S. Army Medical Corps in World War I.

Survivors are his wife Rose and a sister, Sister M. Stanislaus, Mankato.

HERMAN LINDE

Doctor Herman Linde, Cyrus, one of the state's oldest practicing physicians until his retirement several years ago, died May 10, 1959, at the Stevens County Memorial Hospital, at the age of 87.

Doctor Linde practiced medicine in Cyrus for more than fifty years. On August 28, 1955, Doctor Linde's countless friends in his home community paid high tribute to him at an observance in the Cyrus Lutheran church in recognition of his fifty years of practice at Cyrus at that time.

He was a member of the Cyrus Lutheran church, a member of the Cyrus Board of Education for a number of years and president of the Cyrus Commercial Club for eight years.

He served as a health officer in Cyrus and was Pope county health officer for a number of years. He was a member of Golden Sheaf Lodge, No. 133 AF and AM of Morris. He was a member of the West Central Minnesota Medical Association, the Minnesota State Medical Association and the American Medical Association.

Doctor Linde was born at Sogn, Norway, and received his early education in Norway. He came to the United States in 1892 and settled at Fargo, N. D. He graduated from Concordia College in Moorhead in 1898, taught school for three years, then attended Hamline University medical school and graduated in 1905. He established practice in Cyrus that same year.

Doctor Linde was married in 1912 to Hilma Moe. She passed away in 1918. He was married to Inga Hippe on June 22, 1922. She survives him.

LEONARD G. ROWNTREE

Doctor Leonard G. Rowntree, former chief of the Department of Medicine of the Mayo Foundation, and head of a section of medicine in the Mayo Clinic, died at his home in Miami Beach, Florida, on June 2, 1959.

Doctor Rowntree was born April 10, 1883, at London, Ontario, Canada. He received the degree of doctor of medicine from the Western University Medical School, and was an intern in the Victoria Hospital, London, Ontario.

Doctor Rowntree came to the United States in 1906

to establish a practice in Camden, New Jersey. In 1916, he came to Minnesota as director of the Department of Internal Medicine of the University of Minnesota Medical School.

Doctor Rowntree came to Rochester, Minnesota, on April 1, 1920, as head of a section of medicine and professor of medicine in the Mayo Foundation, Graduate School, University of Minnesota. On January 1, 1922, he was appointed head of the Department of Medicine of the Mayo Foundation.

He left the Mayo Clinic and Mayo Foundation in September, 1932, to become director of the Philadelphia Institute for Medical Research and to practice internal medicine in that city. From 1933 to 1955 he was also a member of the advisory board to the Biochemical Research Foundation, and he was chairman of the Deans' Committee for Veterans Administration Hospitals, Miami and Coral Gables, Florida. He also served as chief of the medical division of the headquarters office of the Selective Service System, Washington, D. C., from 1940 to 1945, and in 1944 and 1945 he was chairman of the National Joint Committee on Physical Fitness of the Federal Security Administration. From 1945 to 1950 he was the chief medical advisor and chairman of the medical advisory board of the American Legion, and he was a vice president of the National Committee for Mental Hygiene. He was the recipient of a Presidential Medal of Merit in 1945 from President Truman.

Doctor Rowntree was president of the American Society for Clinical Investigation in 1921, and of the American Society of Endocrinologists in 1929. He was a fellow of the American College of Physicians and a member of the American Medical Association, the American Association for the Advancement of Science, the Association of American Physicians, the American Association for the Study of Internal Secretions, the American Physiological Society, the American Pharmacological Society, the American Society of Biological Chemists, the American Society for Experimental Pathology, the Alumni Association of the Mayo Foundation, Phi Beta Kappa, the Society of the Sigma Xi and the Phi Beta Pi professional medical fraternity.

Doctor Rowntree was married to Miss Katharine Campbell, July 9, 1914. Doctor and Mrs. Rowntree had two daughters: Mrs. Mary Laird Wallace, II, Schnectady, New York; and Mrs. H. Clinton Davis, Miami, Florida.

CLIFFORD N. RUDIE

Dr. Clifford N. Rudie of St. Paul, died April 16, 1959. He was fifty-nine years of age at the time of his death. His specialty was psychiatry.

For the past nine and one-half years, Dr. Rudie had been on the staff of the St. Peter State Hospital. A native of Sissiton, South Dakota, Dr. Rudie obtained his medical education at the University of South Dakota, in Vermillion, the University of Louisville, located in Louisville, Kentucky. In addition, he attended Augsburg College in Minneapolis, St. Olaf College in Northfield and the University of Minnesota. He interned at Miller Hospital in St. Paul. Before moving to St. Peter, Dr. Rudie practiced medicine from 1929-1931 in Mazeppa, Minnesota; 1931-1941 in Kenyon, Minnesota; 1942-1946 in California; and 1947-1949 in Wanamingo, Minnesota.

He was a member of the Nicollet-LeSueur County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors are his wife; three children, Richard, psychologist at the Moose Lake State Hospital, Mrs. James Brislance, Saragosa, Spain, and Frederick Rudie, a senior at St. Olaf college at Northfield; and two grandchildren. Also surviving are his mother, six sisters and one brother all residing on the west coast.

ARTHUR H. SANFORD

Doctor Arthur H. Sanford, former head of the Section of Clinical Pathology of the Mayo Clinic for thirty-five years and director of laboratories at Rochester State Hospital since June 1950, died unexpectedly April 28, 1959, of coronary insufficiency. He was seventy-seven years old at the time of his death.

Doctor Sanford was a member of the Rochester School Board from 1924-40 and served as president for fourteen years of that time. Doctor Sanford also was a president of the Kiwanis Club and the Rochester Community Chest, was honored in 1940 by the Rotary Club for his contributions to the city and was very active in the work of the First Methodist Church.

In May 1957, Doctor Sanford was honored by the Minnesota State Medical Association for fifty years in the practice of medicine.

The annual Arthur H. Sanford lecture in pathology,

presented each year at the scientific sessions of the state medical meeting, is presented in tribute to the Rochester man. It was established by the Minnesota Society of Clinical Pathologists in 1947. In October 1956, he was honored at the annual meeting of the College of American Pathologists with the award of the Scientific Products Foundation.

Doctor Sanford was co-author, with the late Doctor James C. Todd, of "Clinical Diagnosis by Laboratory Methods," a standard text in the field, the twelfth edition of which appeared in 1953, with Doctor Benjamin Wells, as co-author. Doctor Sanford also contributed some one hundred papers and other writings to the literature in his field.

With Doctor Charles Sheard and Dana Rogers of the Clinic, he devised the first successful photo-electric colorimeter for the quantitative determination of hemoglobin and other chemical constituents of the blood. This was reported in 1932, and in 1933, Doctor Sanford was awarded the Ward Burdick gold medal by the American Society of Clinical Pathologists.

Doctor Sanford was born in New Albin, Iowa, January 12, 1882. He enrolled as a student at Northwestern University, from which he received the degree of bachelor of arts in 1904, and the degrees of master of arts in physiology and doctor of medicine in 1907. From 1907 to 1911, he was a member of the faculty of medicine at Marquette University, where he was successively assistant professor, associate professor and professor of physiology. He was licensed to practice medicine in Illinois in 1907, and also in Wisconsin. He was licensed in Minnesota in 1916.

He was a charter member of the American Society of Clinical Pathologists, and in 1927, and 1928, served as president of the society. When the American Board of Pathology, Inc., was founded in 1936, Doctor Sanford was elected first president of the board, a post he occupied until 1946.

Doctor Sanford was a fellow of the American College of Physicians, member of the Minnesota State Medical Association, the Zumbro Valley Medical Society, American Medical Association, American Association for the Advancement of Science, American Society of Immunologists, Society for Experimental Biology and Medicine, Alumni Association of the Mayo Foundation, Society of the Sigma Xi, Alpha Omega Alpha medical honor society, Alpha Kappa professional medical fraternity and Sigma Nu academic fraternity. He was also a 32nd degree Mason (Scottish Rite) and a Knight Templar (York Rite).

Survivors are his wife, Margaret; a son, Doctor A. Raymond A. Sanford, Mankato; four grandchildren, and a brother Harold Sanford of Winter Park, Florida. A daughter, Gertrude, died in 1940, and a son, Dr. Hawley S. Sanford, died in 1948.

SIDNEY A. SLATER

Doctor Sidney A. Slater, Worthington, died June 11, 1959. He was seventy-four years old at the time of his death. Death was due to complications of a previous lung ailment.

Doctor Slater, a renowned authority on tuberculosis, was superintendent of the Southwest Minnesota Sanitarium for twenty-eight years. The deceased was president of the Minnesota Tuberculosis and Health Association from 1938 to 1943 and was on the Board of Directors of the National Tuberculosis Association for twenty-six years. He was also a past vice president of the Minnesota State Medical Association and served for ten years as a member of the House of Delegates.

In addition, Doctor Slater was a past president of the Venengo County Pennsylvania Medical Society, the Southwestern Minnesota Medical Society, the Southern Minnesota Medical Society and the Sioux Valley Medical Society.

The deceased was also a member of the AMA, the American College of Chest Physicians, the American College of Physicians and the American Trudeau Society.

Doctor Slater was born in Enfield, Virginia, and received his medical education from the medical college of Virginia in Richmond.

He is survived by his wife.

Communications

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

THE ADVANTAGES OF THE AMERICAN FREE ENTERPRISE SYSTEM

By Carol Pryor
Elizabeth, New Jersey

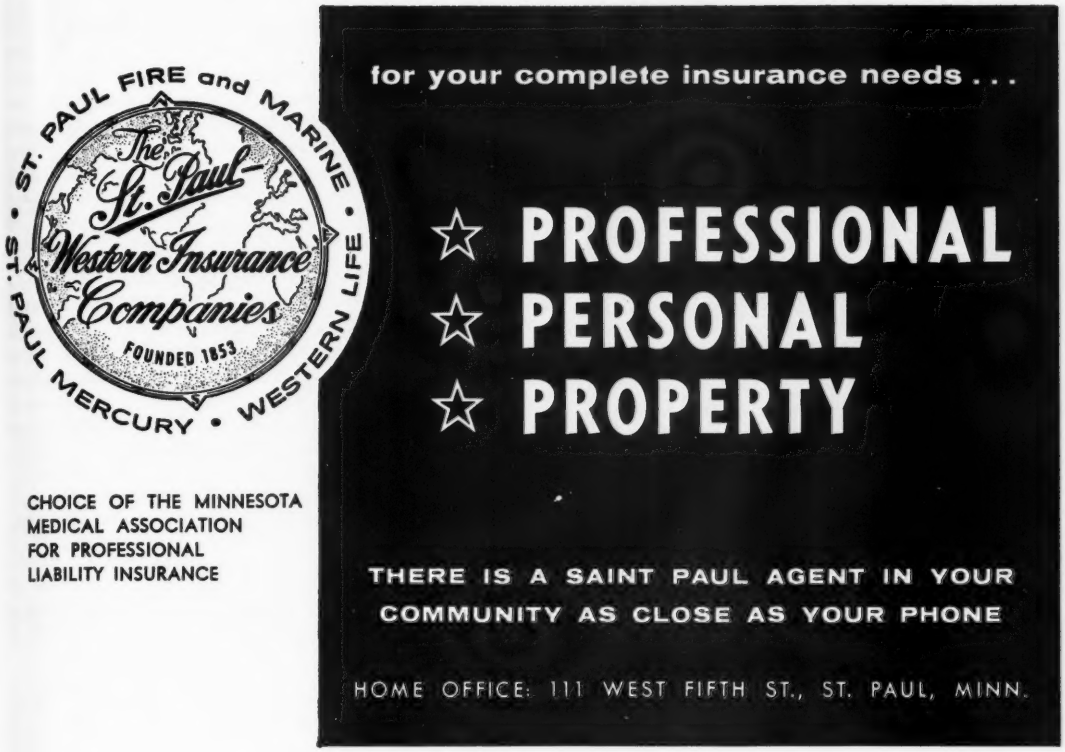
Of all the freedoms enjoyed by Americans, one whose roots lie deep in tradition is that of free enterprise. From the earliest settlement of the new world, our ancestors had to develop means of providing for their daily needs. Food, shelter, and clothing had to be wrested from the natural resources found in this strange, new land which was to be their home.

Because these early settlers were fleeing the serfdom or slavery of their mother countries, they wished to insure freedom for their children in the years to come. In declaring their political freedom, they laid down in that immortal document, the Declaration of Independence, these principles: "We hold these truths to be self-evident: that all men are created equal; that they are endowed by their creator with certain inalienable rights; that among these are life, liberty, and the pursuit of happiness." These men had set their goals and they meant to reach them. To them the possession of private property ranked in importance with freedom of speech, freedom of the press, the right to vote, and the right to engage in whatever profession they chose. "The pursuit of happiness," therefore, implied free enterprise and private ownership.

Exercising their right of private ownership and free enterprise, these pioneers in industry made rapid progress. Before the coming of the railroad, in many communities little industries were carried on in a simple way—a flour mill operated by a water wheel; a wheelwright shop, a chair factory, a pottery, a tinsmithy. The blacksmith, varied the routine of shoeing horses of the countryside with making tools for the farms and households. In the larger towns might be found a bakery or two.

In these early days the owner of the plant was also the master workman, employing either his sons or an apprentice or two. He carried his money in a leather bag attached to his belt, and did his bookkeeping at night by candle-light. He made his own deliveries by horse and wagon to his customers who lived at a distance.

With the advent of the railroad, many small units of industry found it more profitable to form one large unit. However, many of the local manufacturers preferred to carry on their own business, depending upon the loyalty of their customers. As late as 1850, a manufacturer of farm implements could have only five employees and yet be as large as the average. He could be an independent manufacturer, and yet have only $2,600 as his capital. By 1910, it took $400,000 to be an average manufacturer of agricultural implements. In 1859, there were 1333 factories making farm implements; by 1910, the number had shrunk to 640—though quantity of goods turned out had grown in value from $6,000,000 to $146,000,000. This same change occurred in the cotton goods and steel industries. All this was the result of the business man's freedom to consolidate or to remain independent.



Of the old-time businesses that continued independently, one of the best known is the DuPont Company, founded as manufacturers of powder at Wilmington, Delaware, in 1802. DuPont's is now a leader in many additional lines. The wide variety of products, nationally advertised and sold, is evidence of the skill, ambition, and inventive genius of the men who made DuPont one of the monuments to the system of free enterprise.

The automobile industry is another giant that grew out of man's freedom to use his inventive genius and skill. When man realized the need for more efficient transportation, he immediately went to work to design what was known as the "horseless carriage." Although he was laughed at, he was not discouraged. Suddenly the idea caught on, and the demand was greater than the supply. With the development of the assembly line process, cars could be produced more rapidly, and eventually, at a cost within the average man's budget. Now the average family owns at least one and, sometimes, two cars.

Winner of first prize in the 1959 National Essay Contest for high school students sponsored by the Association of the American Physicians' and Surgeons' Freedom Programs in cooperation with state and county medical societies.

In this half of the twentieth century, the supermarket —a distinctly American institution—spurred on by competition—is rapidly becoming bigger and better, offering more space for a greater variety of products. However, the small corner grocery store, the village bakery, and the delicatessen still have their rightful and necessary place in our American way of life. Both types of businesses serve the needs of a rapidly growing population more satisfactorily than any government "planned economy" system could.

Free enterprise is the basis of our American way of life, encouraging people to be creative and ambitious. It provides more benefits for the greater number of people than any other system yet devised by man, and keeps our standard of living high. By contrast, socialism kills incentive. It merely tends to take anything created by free enterprise and dispose of it for "the better interests of humanity" according to the false socialistic way of reasoning. The socialist would put all men on the same level, the hard-working tradesman, the skillful, inventive genius, and the shiftless, good-for-nothing loafer. A famous English scientist once said: "A capitalist is a man who, if he himself is doing well, doesn't mind if others are living better. A socialist, on the other hand, is a man who doesn't care how badly he himself is living as long as nobody else is allowed to live better."

A. M. Rosenthal, correspondent for the *New York Times* in Poland, made this comment in one of his articles published recently: "This reporter after years in a would-be Socialist country and in a Communist area, finds himself influenced quite sharply by his experiences. Month by month his appreciation of the expansiveness and variety of American life, in contrast to the sort of drab prissiness in which socialism and communism wrap themselves, grows."

West Germany has provided a good example of free enterprise. After the second World War, she had a choice between the European and United Kingdom socialist pattern (heavy control, rationing, tremendous emphasis on equality) or free enterprise (emphasis on incentive and free marketing). West Germany chose free enterprise and has risen to the status of an economic and financial king in Europe.

In our own country, government control in agriculture has proved a failure. Ezra Taft Benson, Secretary of Agriculture, has said that he felt the great majority of farmers would much prefer to have less government in agriculture, rather than more. He believes it is necessary to recognize that "controls are a failure; that you can't effectively control production by legislation."

In spite of what experience has proved in our own country and abroad, there are many so-called Americans abusing the democratic system of free competitive enterprise. They contend that the government owes a living to any citizen or group of citizens; that it should provide special privileges and benefits to various communities. What they are actually clamoring for is the destruction of freedom of action and opportunity. Furthermore, they fail to realize that before the government puts a dollar into the hand of anyone, it must first take that dollar out of his pocket, plus the cost of collecting, bookkeeping, distribution, et cetera.

From the window of our school library, I can see every day what I think is one of the greatest tributes to our American system of free enterprise. To me it represents free enterprise on the move—a well-used railroad transporting hundreds of freight cars daily, carrying State of Maine products, Florida fruits, oil, coal, live stock, scrap metal, and dozens of other raw materials and finished products. Through the underpass of this

same railroad runs one of America's busiest highways. Conveyances of all types pass here in a steady stream. It is a familiar sight to see a small truck farmer bringing his produce to market behind a giant trailer truck carrying four bright, new cars to their destination. In another lane a huge oil truck will pull up beside a gaily painted florist's delivery car. And so the endless procession goes on day and night—trucks of all sizes, shapes, and models, carrying the fruits of man's labor to all parts of the country. Would the picture be the same if all these industries represented were government controlled?

America has come a long way since the day of the village blacksmith, the country store, and the horseless carriage. She has amazed the world by her progress. Only by man's freedom to produce according to his capacity, and to consume or dispose of what he produces according to his own judgment, respecting the rights of others, has this progress been accomplished. Those who still believe in our constitutional democracy have a sacred responsibility to protect this right of the individual—"The right to life, liberty, and the pursuit of happiness" by fighting to hold fast to our American system of free competitive enterprise.

There were 24,830 pedestrians injured crossing intersections *with* the signal in their favor during 1958 in the United States.

The Physician's Diary

Dr. William S. Pollard, Duluth, was recently certified by the American Board of Neurologic·Surgery at a meeting in St Louis, Missouri. In addition, he recently addressed the staff meeting of the Itasca County Memorial Hospital in Grand Rapids on "The Management of Head Injuries."

* * *

Dr. John F. Briggs, St. Paul, recently gave the Louis Mark Memorial Lecture before the American College of Chest Physicians in Atlantic City, New Jersey. Dr. Briggs spoke on "Optimism in Heart Disease." The Louis Mark Memorial Lecture is in memory of the late internationally known chest physician who was a native of Minnesota.

* * *

Dr. Franklin C. Anderson, Owatonna, has been named medical consultant for the Federated Life Insurance Company. The position is on a part-time basis allowing Dr. Anderson to continue to devote the major part of his time to his position at the Owatonna Clinic.

* * *

An exhibit, "Misleading Thoracic Roentgenograms: Abnormalities That May Stimulate Diseases of the Lung, Bony Thorax or Mediastinum," by **Drs. C. H. Hodgson, John A. Callahan** and **Arthur H. Bulbulian,** of the Mayo Clinic, and Dr. André J. Bruwer, of Tucson, Arizona, formerly of the Mayo Clinic, was awarded the blue ribbon, or first award, among scientific exhibits at the Industrial Health Conference sponsored by the Industrial Medical Association and other organizations in Chicago recently.

* * *

Among twelve Minnesota scientists receiving research grants totaling $136,604, were **Dr. Richard A. DeWall** and **Dr. Cecil J. Watson,** both of the University of Minnesota. The announcement was made recently by **Dr. Karl W. Anderson,** President of the Minnesota Heart Association.

* * *

Dr. John W. Kirklin, Mayo Clinic, is one of 170 doctors who have been elected to fellowships in the American Academy of Pediatrics, the Academy has announced.

* * *

Dr. N. N. Ninneman has joined the medical staff of the St. Peter State Hospital. Leaving private practice at Waconia, Minnesota, Dr. Ninneman began his duties at that institution recently.

* * *

The St. **Louis County Medical Society** co-sponsored the annual Florence Nightingale dinner along with the Second District Nursing Association and the Northeastern League for Nursing Hospital Administrators. Guest speaker of the evening was George Grim, Minneapolis reporter, analyst and lecturer.

Governor Orville L. Freeman has appointed **Dr. John A. Callahan,** Mayo Clinic, a member of the Minnesota State Board of Examiners in the Basic Sciences, for a six-year term expiring on April 1, 1965.

* * *

Dr. Rauen Curtis, LeCenter, has resumed his medical practice on a limited basis following a severe heart attack several months ago.

* * *

Dr. Melvin G. Oppen, Wayzata, and **Dr. Roger S. Johnson,** Excelsior, have been added to the staff of Doctors Memorial Hospital, bringing the staff to seventy-three.

* * *

Recently elected a director-at-large of the National Tuberculosis Association was **Dr. David T. Carr,** Mayo Clinic, at the Association's annual meeting, held in the Palmer House in Chicago. Another Minnesotan, Mrs. C. L. Oppegaard, Crookston, was elected to the board.

* * *

Thirty physicians and their wives assembled in the Elks Club, Thief River Falls, for the annual spring dinner meeting of the Red River Valley Medical Society. **Dr. H. D. Clapp,** Crookston, president, was in charge of the program which included a paper on "Cholesterol Metabolism" by **Dr. Rolf Andreassen,** Minneapolis.

* * *

Dr. O. F. Ringle, Walker, has leased the former Walker Hospital building to the Cass County Welfare Board for new offices and quarters. Dr. Ringle will continue to operate his clinic on the North end of the first floor of the building.

* * *

Dr. C. O. Hansen, Minneapolis, has been named to a five member commission to govern the Hennepin County Tuberculosis Sanatorium at Glen Lake. He will serve in that capacity until May 1, 1962.

* * *

Dr. Lloyd T. Wood, formerly of Forest Lake, has been elected a partner of the Olmsted Medical Group. The other partners are **Drs. H. A. Wente, J. R. Doyle, J. E. Verby, J. R. Watson, H. F. Burich, M. K. Campbell, W. R. Weyhrauch,** and **J. C. Brodhun.**

* * *

A $1,000 grant for research in arthritis has been awarded **Dr. Charles A. Slocumb** of the Mayo Clinic. Dr. Slocumb is a former president of the American Rheumatism Association.

* * *

Spring Valley physician, **Dr. L. W. Clark,** was recently honored by that community for his fifty years of service in the practice of medicine. The "Dr. Clark Day" observance included an open house and program held in Our Savior's Lutheran Church of Spring Valley. Most of his medical practice has been in Spring Valley and Chester, Iowa.

Dr. Darwin K. Holian, Albert Lea, was a recent speaker at a meeting of the Albert Lea Kiwanians. He spoke on advances in surgery during the past twenty years.

* * *

Dr. H. P. Hinderaker has announced that he is discontinuing practice with **Dr. Leo O. Furr** of Bird Island. He will be resuming practice in Willmar, Minnesota.

* * *

The Patton, California, newspaper has announced that **Dr. D. H. Garlock,** a former practicing physician from Bemidji, Minnesota, has retired. Dr. Garlock expects to spend his summers here in Minnesota.

* * *

Dr. John W. Schut, Anoka, recently announced that he has given up his medical practice. Dr. Schut plans to spend his time in the research of ataxia, of which he is a victim.

* * *

Dr. A. M. Scheidel, Mankato, recently returned from Chicago where he passed the second part of a two-part test given by the American Board of Internal Medicine. Dr. Scheidel took the first part of the Board Certifications test last October.

* * *

Dr. E. S. Boone and **Dr. A. C. Martin,** Luverne physicians, will share a new building beginning approximately on October 1. The building will house separate offices for the two physicians.

Triumph physician, **Dr. Edgar R. Gamm,** recently began practice in Park Rapids. Dr. Gamm is in partnership with **Dr. Norman J. Haugan** and **Dr. Paul T. Grimes,** in the new Medical Arts Building.

* * *

Dr. James W. DuShane, head of the Section of Pediatrics of the Mayo Clinic and associate professor of pediatrics in the Mayo Foundation, has recently been elected to membership in the American Pediatric Society. The announcement was made at the society's annual meeting at Buck Hill Falls, Pennsylvania.

* * *

At the annual meeting of the American Dermatological Association in Atlantic City, New Jersey, recently, it was announced that **Dr. Harold O. Perry,** Mayo Clinic, had been elected to membership in that society.

Newly elected president of the Ramsey County Tuberculosis and Health Association is **Dr. George C. Roth,** St. Paul. He succeeds Edward A. Knapp, who had been president since 1945.

* * *

Lakefield citizens recently honored **Dr. J. T. Rose,** at a recognition dinner of his fifty years as a rural doctor. Dr. Rose has practiced forty-six years in Lakefield.

* * *

The Board of Directors of the Minnesota Alumni Association recently conferred on **Dr. Lillian Nye,** St. Paul, the title of Graduate Emeritus for her fifty years of loyalty to the University of Minnesota at the golden anniversary reunion of the class of 1909.

* * *

Dr. Sheldon L. Mandel was a guest lecturer at the June meeting of the Montana Section of the American Academy of General Practice which was held at East Glacier Park, Montana. Dr. Mandel spoke on "Recognition and Treatment of Common Dermatologic Problems" and "Drug Reactions: Cutaneous and systemic Manifestations."

* * *

Professor Richard G. Bond, director of the division of environmental health and safety in the University of Minnesota Health Service, recently received word that he has been elected an honorary fellow of the Royal Society of Health of Great Britain. This honor is conferred upon persons who have distinguished themselves in connection with the promotion of health.

A graduate of the Universities of Iowa and Minnesota, Professor Bond was at the University as a visiting lecturer in the school of public health in 1944 and 1945 and returned to join the Health Service staff in 1949.

He is a member of the governing council of the American College Health Association and has served as consultant to the National Institutes of Health of the United States Public Health Service. He presented a paper at the Royal Society's annual meeting last April.

The Royal Society of Health is the counterpart of the American Public Health Association. Since its founding, approximately 100 honorary fellows have been elected from countries throughout the world. Professor Bond is one of some thirty elected from the United States.

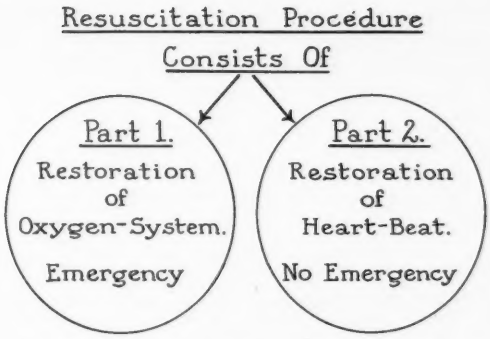

Fig. 1. This separation gives scientific order to the procedure when orderly conduct is a requirement for success.

Resuscitation of the Heart

CLAUDE S. BECK, M.D.
DAVID S. LEIGHNINGER, M.D.

Department of Surgery, Western Reserve University and University Hospitals

Cleveland, Ohio

THE purpose of this paper is to discuss death from the standpoint of its reversibility. "Reversal of the death-factor" is a strange combination of words with a meaning that probably is unfamiliar. The terms "temporary death" and "permanent death" may also be unfamiliar. We believe that there is now a place in our medical thinking for these terms and we shall try to give them meaning.

In Moscow there exists a "Resuscitation Institute" and in each large hospital of that city there is a group whose efforts are directed only to "Resuscitation." This group has charge of death, so to speak, and it functions not only in the operating rooms but throughout the hospital. This development has potential military value and is, therefore, important. For surgical operations a systemic artery is routinely exposed but it is not cannulated. This artery is exposed so that oxygenated

The illustrations in this article are by permission of Surgical Clinics of North America. They were made by our esteemed artist, Theodora Bergsland of Red Wing, Minnesota.

blood can be given into this artery without delay should it become necessary. This is one of the Russian ways to meet an emergency. It involves

Fig. 2. Required equipment with every patient for every operation and every diagnostic procedure in x-ray. Standing rule of the hospital.

a serious and drastic step towards protection of the patient. In this respect Russia is ahead of America in taking steps to protect the patient during operation. In America most of the hospitals do not even possess the necessary equipment for resuscitation and little or no effort has been made to train the staff in methods of resuscitation. Perhaps legal action in the courts will be necessary to correct this deficiency. In many of our medical schools there is no instruction in this subject.

Time of Death.—The end of life and the beginning of death must have a sharp and instantaneous line of separation between the two. The purpose of this sharp and instantaneous line is to start the race against time for resuscitation. To delay this race is to invite failure. Death begins as soon as the oxygen-system breaks down, as soon as the heart takes its last forceful beat, as soon as the patient takes his last breath. The brain cannot get along without a constant supply of oxygen. If the oxygen-system is broken down for three to five minutes, degenerative changes of an irreversible nature set in. This is a key-point in resuscitation. It makes no difference to the person or persons who do the resuscitation procedure as to the definition or timing of death. There is this period of time when death may be considered temporary and reversible but to the man of action, death begins at the breakdown in the oxygen-system. If death begins when there is no possibility of resuscitation then the man, woman or child is alive up to that time and if he is alive there is no purpose in carrying out this unpleasant job of resuscitation.

This timing of death negates action. It is for the religious officer and for the physician who does not believe in resuscitation or does not understand resuscitation. To try to resuscitate is to invite failure. To fail is to invite criticism. To

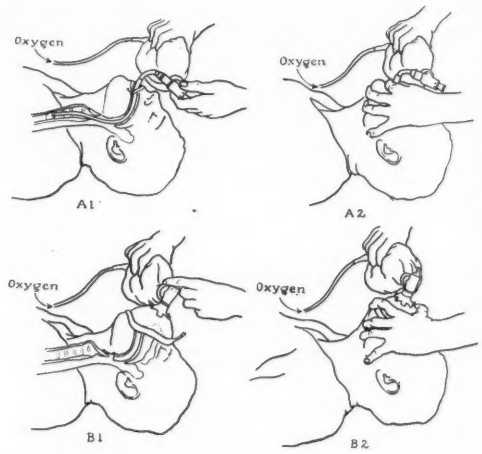

Fig. 3A-B. Intratracheal tube and a bag of oxygen provide the best method of putting oxygen into the lungs (A1 and A2). A face mask and an air way is the next best method. The chin is held up. The pharynx is cleared of vomitus and secretions. (B1 and B2).

do nothing is to be perfect. Death has no spokesman, no one to speak out against the living for improper action or for no action. Indeed, the living are afraid of death and being afraid of death they hate the dead. There is much evidence to support these statements.

Who Should Not Be Resuscitated?—Death may be a release from life in a body-structure scarcely able to live. There are many such instances where incurable disease has run its course, where death is desirable. There are many instances in which the heart cannot support its own beat, when the lungs cannot oxygenate the blood, when the brain cannot co-ordinate its own activity and when the various systems in the body cannot function. Resuscitation should not be tried after the brain has been damaged, after the oxygen-system has been broken for periods longer than six minutes. On the positive side are many instances where it

should be tried—in humans with a good heart and lungs, and whose body is too good to die. Examples are the child who has appendectomy and dies and the man whose heart electrocutes itself and the heart structurally is too good to die (fatal attack of the heart).

Where Can Resuscitation Be Done?—There are certain requirements for resuscitation. The full-equipment of an operating room is not necessary. Only a few items are necessary and if these items are available, resuscitation could be done outside the hospital. Attempts are being made outside the hospital including opening the chest and pumping the heart. These attempts when done by trained personnel and under proper conditions

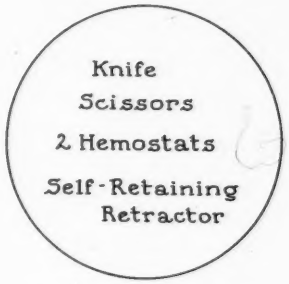

Fig. 4. Equipment to open the chest, kept in a sterile package with the Roswell Park airway and face mask on hospital wards.

are to be encouraged. It is a brave and noble thing to try to save a life and it shows man at his best. Recently a man choked on a piece of meat. Two sons, farmers, cut open the trachea, placed a piece of fountain pen in trachea, saved his life. People can be trained to do these things, even to opening the chest and pumping the heart. Progress will be made in this direction. Victims of fatal heart attacks are being saved in the hospitals. The time will probably come when this will be accomplished outside the hospital.

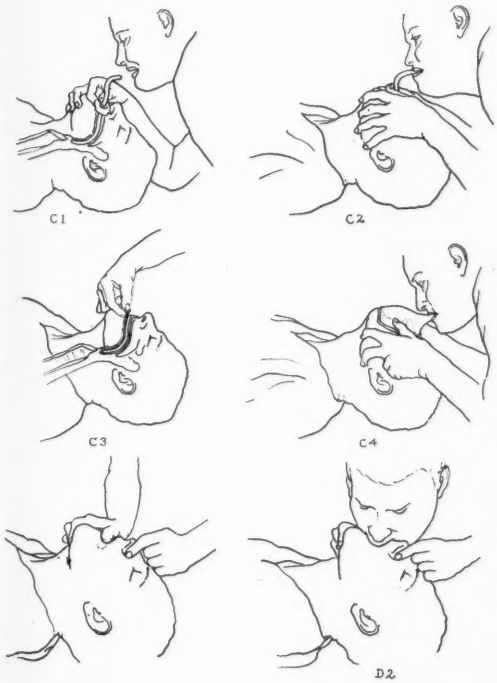

Fig. 3C-D. Inflation of lungs with air. C1 shows a double pharyngeal airway. C2 shows elevation of the jaw with two hands and closure of the nostrils between the two thumbs. The rescuer blows airway. These double airways are in two sizes one for adults, one for children (Safara Airway—can be procured from T. F. Finnigan, 3819 Lancaster Ave., Phila. 4, Pa.). C3 and C4 show a pharyngeal airway and a face mask which covers the mouth and nose and into which air is blown. The jaw is elevated (Breathing mask can be procured from Roswell Park Memorial Institute, Buffalo 3, N. Y.) D1 and D2 show mouth-to-mouth breathing. The thumb of the right hand is inserted into the mouth and the jaw is elevated. The nostrils are squeezed together. Mouth-to-mouth contact is made with thumb in patient's mouth. All food and water are wiped out of the victim's pharynx. These airways should be distributed throughout the hospital. It is advisable for the physician to carry one of these airways in his pocket.

Prevention of Death So Resuscitation Is Not Necessary

This is an important area for proper action. "An ounce of prevention is worth a pound of cure." This applies to the operating room and elsewhere in the hospital and outside the hospital. This subject is too broad to try to discuss in this article. The following items are important: the maintenance of an open airway; stopping the anaesthetic; administration of oxygen; replacement of blood; correction of position of the patient; the Trendelenburg position; good aeration of the lungs; and the use of adrenalin, wyamine, levophed and cedilanid. Tension pneumothorax, cardiac compression, dislocation of the heart, abdominal or gastric distention, intracranial pressure, pulmonary embolus, fluid in chest are items that can lead to death. Preparation for resuscitation is sometimes possible before the patient dies. Things can be gotten ready for action before action is necessary.

The Resuscitation Procedure

The resuscitation procedure consists of two parts. One is restoration of the oxygen-system. The other is restoration of the heart-beat (Fig. 1). One is the emergency act. The other is not. To understand the procedure, this separation must be accepted as "the gospel." Without clear understanding of this, the procedure is likely to be disorderly. Understanding of it produces order and this is a crisis in which there is need for orderly action. To do the wrong thing at the wrong time may cost a life.

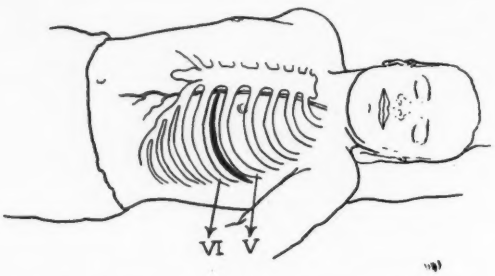

Fig. 5. Incision between two ribs. Time is not taken to count; time is not taken for asepsis. The incision is 8 inches long for an adult and 6 for a child. Location of internal mammary artery is noted. If cut it will not bleed at this time and can be ligated later.

Restoration of the Oxygen-System.—This also consists of two parts. One is to get oxygen into the lungs. The other is to open the chest, pump the heart by hand and circulate the oxygen to the brain. Each will be discussed.

To Deliver Oxygen into the Lungs.—It is possible to be caught short on this without preparation and without equipment and thereby to lose a life. The best way to get oxygen into the lungs is to have a tube in the trachea, to connect the tube to a rubber bag containing oxygen and to squeeze the bag by hand. Every hospital should have a rule that "No surgical procedure, no diagnostic test in x-ray is to be done without required equipment with the patient." This equipment consists of an intratracheal tube, a laryngoscope, a rubber bag and a tank of oxygen (Fig. 2). The intratracheal tube and the bag of oxygen is shown in Figure 3 A1 and A2. A face mask without the tube but with an airway is shown in Figure 3 B1 and B2. The chin must be elevated. The pharynx must be cleared out of vomitus and secretions.

There are other ways of inflating the lungs when the person doing the resuscitation blows air from his own lungs into the lungs of the victim. Figure 3 C1 and C2 shows a double airway; C3 and C4 show a pharyngeal airway plus a face mask which is collapsible and which is recommended; D1 and D2 show mouth-to-mouth insufflation.

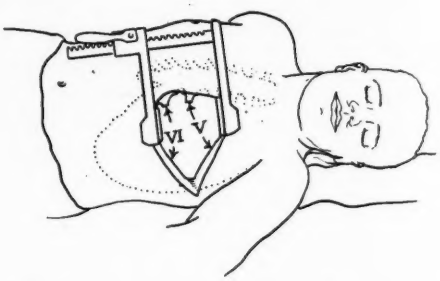

Fig. 6. Two or more costal cartilages are cut across and the ribs are held apart while a hand is placed in the chest and the heart is pumped as soon as possible. A self retaining retractor is placed while pumping proceeds.

These are make-shift methods to be carried out until the methods illustrated in A and B can be brought into use.

Another method which should be mentioned is the use of tracheotomy. This may be life-saving when the patient chokes and the obstruction cannot be removed from the pharynx. It can be done as an emergency by non-medical personnel using a pocket knife and inserting the open end of a fountain pen into the trachea. Since it may save life there is urgency to do it.

To Circulate the Oxygen.—The best way to do this is to open the chest and to pump the heart by hand. The equipment for this is shown in Fig. 4. This can be kept as a sterile package in various areas in the hospital together with the Roswell Park Airway and face mask. This affords essential equipment on wards of hospitals.

Incision.—Time is not taken to sterilize the hands or the victim's chest. It is not taken to count the ribs. The best level is between the fifth and sixth ribs and costal cartilages. It is of no consequence if the incision is one rib higher or lower (Fig. 5). The incision is about 8 inches long for an adult and 6 inches for a child. Two costal cartilages are cut. Ribs are held apart while a

hand is introduced to pump the heart as soon as possible. A self-retaining retractor is a great help and is introduced while the heart is being pumped (Fig. 6). The emergency is now over—provided the lungs are inflated and deflated and provided the heart is properly pumped. The next step can be considered. If this job has been done

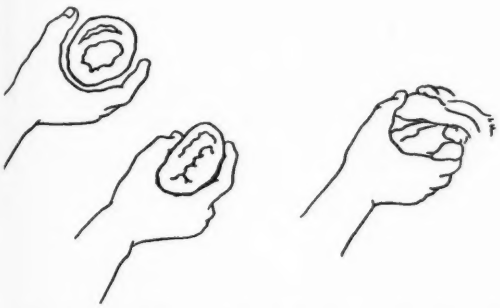

Fig. 7. Illustration on the left shows relaxation of grip to allow filling. It also shows the hand squeezing the empty heart which is to be avoided. The illustration on the right shows the usual grip on a child's heart, using the right hand with the fingers over the left ventricle and the thumb over the right ventricle.

on a medical ward the entire situation is moved to the operating room. The incision is draped with sterile linen and a surgical team takes over the pumping of the heart. A mechanical respirator can be used if one is available. We prefer the Rand-Wolfe Respirator. The lungs should be satisfactorily inflated and deflated in a regular, rhythmic manner. They should come up nicely and go down nicely. Inadequate ventilation may lead to failure. A machine does this job better than the human hand squeezing a bag.

Pumping the Heart.—The heart is pumped by the bare hand as soon as the chest is opened and before the pericardium is opened. There are several points concerning this subject. Both ventricles should be emptied. This means that the right ventricle as well as the left ventricle should be squeezed together. After the ventricles have been emptied the pressure on the heart is completely relaxed so that the heart can fill. It is to be recognized that there is no force to drive blood into the heart. Another point is not to squeeze the empty heart because this only bruises the myocardium. It is possible to stick a finger into the heart or to rupture the heart. A little experience is helpful but good pumping action is possible without experience. The best grip on the heart is to be determined by the person doing it. A child's heart can be pumped by the right hand;

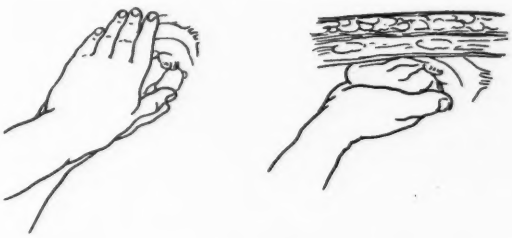

Fig. 8. Illustration on the left shows the adult heart being pumped by the fingers of the right hand over the left ventricle and the fingers of the left hand over the right ventricle. Illustration on the right shows the heart being compressed against the sternum.

the fingers are beneath the heart and the thumb covers the right ventricle. The heart can be squeezed against the sternum. The adult heart is squeezed by both hands; the fingers of the right hand are beneath the heart and the fingers of the left hand are over the right ventricle. These points are illustrated in Figures 7 and 8. It is necessary to have enough room to do a good pumping job on the heart. The chest should be opened as widely as necessary so that the blood can be moved. We have seen an ophthalmologist try to do this through a button-hole incision in the chest and he lost his patient. We have also seen a gynecologist, in gloves and gown, paralyzed into inaction before an operation was started and his patient died. After the heart has been pumped for one or two minutes, time is taken to open the pericardium. The two hemostats and the scissors are prepared for placement in the surgeon's hand so that pumping will be interrupted for as short a time as possible. While he is pumping the heart, he notices where the phrenic nerve is located. He also decides where he is going to grasp the pericardium in the hemostats and where he is going to slit from apex to base. Then he stops pumping and opens the pericardium. Sometimes, if the heart is in standstill, it will start up without opening the pericardium and this is, of course, very good. Pumping is more efficiently done with the pericardium opened.

The crisis is now over. The lungs are inflated. Oxygen is circulated. The blood pressure by pumping is about 80 mm. Hg. A pulse can be felt in the carotid artery with each pumping action

of the hand. The pressure can be raised somewhat by using the index finger of the left hand and compressing the thoracic aorta (Fig. 9). This

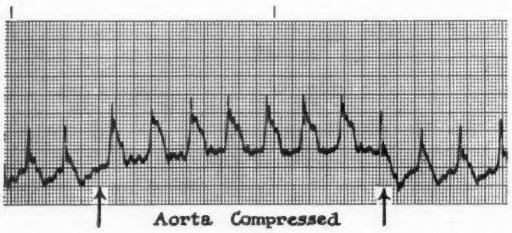

Fig. 9. Blood pressure (in a dog) produced by pumping the heart. It is enough to protect the brain. Pressure is elevated by compression of the aorta.

improves coronary and cerebral circulation. It may be done intermittently. A needle is placed in a vein of the foot for administration of 5 per cent glucose or blood if there has been any blood loss. The circulation should not be overloaded but an adult can take a unit of blood or 500 cc. of glucose solution. Lanatoside C (Cedilanid) is given intravenously in dosage of 2 to 4 cc. or 0.4 mg. or 0.8 mg. This drug is supplied in ampules. It has the same effect as digitalis. It takes effect in about twenty minutes. Ice bags are placed around the patient, between the legs, on each side of the body, and over the neck. Reduction of temperature protects the brain. One must always watch the pumping of the heart and check on the lungs. The oxygen-system must never be needlessly interrupted. The emergency is now over and everyone can relax. Life is no longer in the balance, so to speak.

Restoration of the Heart Beat.—This is Part 2 of the Resuscitation Procedure. It is the easy part, and it is not to be attempted until Part 1 is done satisfactorily. These two parts are not to be confused. Do not be concerned about the heart beat when you are trying to save the brain. From this point on, you can continue to save the brain by carrying out the procedure you so quickly brought into being and you can now concern yourself with the heart beat. The necessary adjuncts are shown in Figure 10. These are two syringes with 22-gauge needles and two medicine glasses containing diluted adrenalin and 1 per cent procaine. There are no other drugs that are any better or as good as these. We have tried them all. These adjuncts can be gotten ready while the heart is being pumped in Part 1. They need not be stand-by equipment as in Part 1.

Ventricular Standstill or Asystole.—Usually the heart starts beating after one or two minutes of pumping. A good heart (without structural disease) wants to beat. Often all it needs is a sec-

Fig. 10. Adjuncts for restoration of the heart beat. No other drugs are as good as these.

ond chance to beat. If it does not start after several minutes of pumping, the pumping is stopped just long enough to observe the heart.

It is interesting that up to this time the heart has not been observed because pumping took precedence over everything else. It is now observed for five to ten seconds. The trained eye can tell whether it is in standstill or fibrillation. For discussion we assume that it is in standstill. An electrocardiogram can be obtained at this point but not before this point. The tone of the heart is determined by the way it feels while the hand pumps it.

If it does not start, the best drug is adrenalin. The assistant gets this ready (4 cc. of the diluted solution) and puts it into a syringe with the needle attached and held properly so that the pumping hand can take it and inject it into the cavity of the right ventricle—not into the the substance of the heart and not into a coronary artery (Fig. 11). This should take but a few seconds. Pumping is immediately resumed. As the drug goes through the lungs, back to the heart, out the aorta and into the coronary arteries the effect on the muscle can be readily felt. The tone improves. Usually it starts to beat. If it does not start to

beat, you check oxygenation of the lungs. They must come up nicely and go down nicely. You check the pumping of the heart and decide whether you are emptying the heart properly. The heart should be nice and pink. If it is not pink, then there is something wrong and correction is in order. If a closed oxygen-system is used, it is

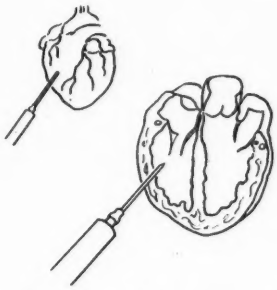

Fig. 11. Administration of drugs into the cavity of the right ventricle. The needle is inserted at an angle. The drug is not injected into the muscle. Coronary arteries are avoided.

possible that the soda lime is not absorbing the carbon dioxide and fresh soda lime should be used. However, almost always the heart starts beating if it is a good heart. Additional injections of adrenalin may be necessary.

Ventricular Fibrillation.—This is characterized by inco-ordinated twitching of the ventricles and resembles the movements of a group of earthworms. It is a convulsion of muscle fibers (Fig. 12). The movement may be coarse or fine. Coarse fibrillation is more favorable than fine fibrillation. The fibrillating ventricles pump out no blood (Fig. 13). Fibrillation of the ventricles must be stopped before the beat can be restored. Occasionally, but not often, fibrillation stops spontaneously.

Occasionally fibrillation occurs when the heart is pumped. The method for stopping fibrillation consists of sending an electric current through the muscle. An electrode about 5 to 7 cm. in diameter is placed on each side of the heart (usually over left and right ventricles but sometimes anteriorly and posteriorly) to shock the ventricular septum (Fig. 14). Ordinary electric light current is used (110 volts). The amount of current is 1 to 2.5 amperes. The current is kept on for about one second. Sometimes repeated shocks in rapid succession are given while moving the electrodes to different areas of the heart.

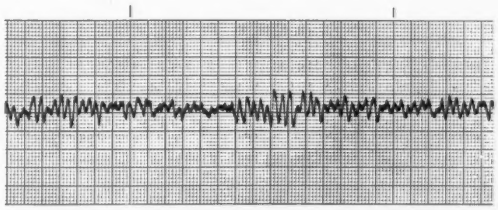

Fig. 12. Electrocardiogram of a fibrillating heart, no co-ordinated complexes.

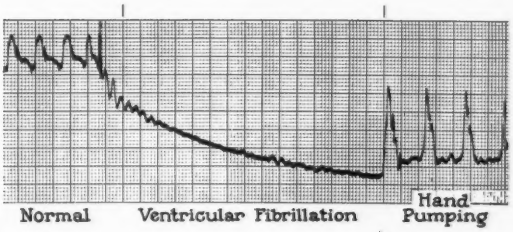

Fig. 13. Blood pressure—normal—during fibrillation—during hand pumping. The fibrillating ventricles pump out no blood.

These shocks also produce contraction of the arms and chest muscles. The electrodes are wet to make good contact. The handles are insulated so that the surgeon does not get shocked. The electrocardiogram is disconnected at the time of shock. The shocking device is special equipment and should be available in every hospital. A few seconds only are taken for shocking the heart. An assistant holds the electrodes so that the surgeon can take them readily, apply them, deliver the shock and resume pumping the heart without delay. If it goes back into fibrillation, several checks are in order. The lungs must come up and go down nicely. The heart should be well oxygenated by proper pumping. If fibrillation continues, 2 to 4 cc. of the adrenalin solution are given. This usually restores tone, improves the color of the muscle and produces a coarse type of fibrillation. Another shock may be effective. If it is not effective, then 4 cc. of procaine are given. This reduces tone and makes the muscle less irritable. Another shock is given.

As a rule the heart comes out of fibrillation readily unless severe disease is present in the heart. The purpose of the shock is to make all muscle

fibers contract at one time with the expectation that they will relax at one time and produce standstill which is followed by a co-ordinated beat.

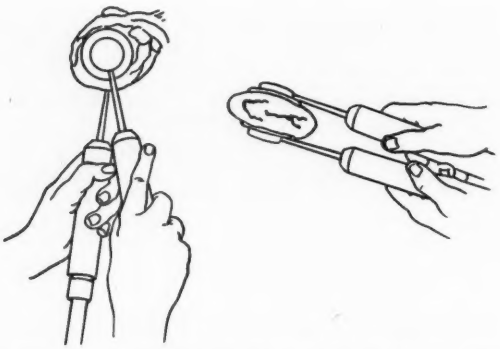

Fig. 14. Application of electrodes to the heart. The heart is emptied of blood by squeezing the electrodes together before the shock is applied.

This beat may be weak and the heart may have to be pumped intermittently. Adrenalin may be necessary. If success is not achieved by the use of adrenalin, procaine and Cedilanid, our experience has been that potassium chloride to abolish fibrillation and calcium chloride or calcium gluconate to restore tone will not be successful.

After the Beat has been Restored.—The pericardium is not closed. A drainage tube is placed in the lower chest and under-water-seal or gentle suction is applied for forty-eight hours. Penicillin and streptomycin are applied to the operative field and instilled into the chest. Antibiotics are given for several days. Bleeding from the wound is controlled. The cut cartilages are removed (leaving the perichondrium) because they may become infected. Closure is by catgut. General anaesthesia may be necessary (Fig. 15).

After Closure of the Chest.—The patient is given oxygen by intra-nasal tube or oxygen tent. The use of ice bags is continued if signs of cerebral damage appear. Pressor drugs may be necessary. Cerebral edema is a complication if the patient does not regain consciousness. Various drugs may be needed as follows: mephentermine, neosynephrine, levophed, atropine, caffeine, hydrocortisone. For cerebral edema and unconsciousness, hypothermia (30° to 34° C.) has been recommended.[1] It has been continued for as long as seventy-two hours. Serum albumin and dehydration may be indicated. Intravenous sedation may be necessary. Digitalis therapy is recommended. An open airway is maintained. Tracheotomy may be indicated. Mechanical respirator (Rand-Wolfe, Drinker or some other device) may be necessary.

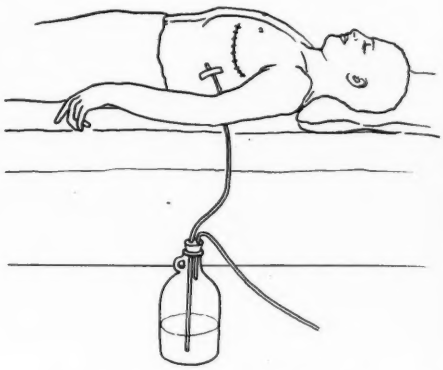

Fig. 15. Closure of the chest. Underwater seal to drainage tube.

Key Points.—Do not wait too long before establishing the oxygen-system. Make sure the lungs come up and go down nicely. Pump the heart correctly. Do not interrupt pumping except when necessary and make the interruption as brief as possible. Demand that your hospital have defibrillation equipment. The absence of such apparatus may be the basis of legal action in the courts. Use drugs sparingly. Maintain an open airway. Use hypothermia and, if necessary, pressor drugs.

Pacemaker and External Defibrillator (Figure 16)

In recent years, there has been discussion in the medical newspapers and journals concerning the value of the pacemaker for resuscitation. It became necessary to demonstrate the pacemaker in our course on resuscitation so that we could determine whether or not it is of value. Our experience has been that it is of no value in starting the heart after the heart has stopped either in asystole or ventricular fibrillation. Even if it is applied directly to the heart it does not produce a beat. The heart becomes anoxic as soon as it stops pumping blood. Sixty seconds of anoxia destroys the power of contraction. The electrical impulse may be present but the muscle will not respond. This is an important point because one

might be led to try it and thereby lose the opportunity for saving a life. The pacemaker is effective in heart block and in the Stokes-Adams syndrome but it has no place in resuscitation of the stopped heart.

Fig. 16. Pacemaker and external defibrillator. Left—The Birtcher Heartpacer, model 230 made by the Birtcher Corporation, Los Angeles, California. Right—The Morris External-Internal Defibrillator, model EID-1 made by the Levinthal Electronic Products, Inc., Redwood City, California. Neither is recommended in the Resuscitation Procedure. Not to pump a stopped heart by hand violates all principles of Resuscitation.

Recently, shocking the heart out of fibrillation by the use of external electrodes on the chest was advocated and many physicians read about its use. Again, we incorporated this into our course and again we found that it had no value in resuscitation of the heart after it stopped in standstill or in fibrillation. This is an old method used by the electric utility companies when a man touches a live wire on a pole. It has had limited value in the past. The electrodes are large. One is applied over the apical region of the chest; the other is applied over the sternum so that the current traverses the heart. Ten amperes and 1,000 volts are used. When a dog's heart is fibrillated by an electric current, the fibrillation is verified by the electrocardiogram. After waiting seventy seconds, an external shock is given. This will defibrillate the heart as shown by the electrocardiogram. It gives the false impression that the heart is beating because the complexes are normal. However, there is no pulsation of the arteries and there is no pumping action of the heart. If the shock is applied before seventy seconds, a pulse might be produced. If the heart is not circulating the blood, all principles of resuscitation are violated if the heart is not pumped by hand. The use of the pacemaker and/or the external difibrillator may be the cause of failure.

Arterial Transfusion.—The question is often asked whether arterial transfusion of oxygenated blood has a place in the resuscitation procedure. The answer is sometimes given in the the affirmative. This, we believe, is the wrong answer. It may have a place only if an artery has been exposed so that the blood can be pumped into the arterial system as is done in Russia. If one has to take time to get oxygenated blood and then put it into an artery (and this may involve cutting down on the artery), the opportunity to save the brain may be lost. If the heart fails to start beating after the blood is given, then this means failure. There is no substitute for pumping the stopped heart. This is no place for experiment and to try any procedure to see whether it works.[2]

Gouty Arthritis

Current Concepts in Treatment and Control

Presented at the Clinical Session of the American Medical Association, Minneapolis, Minnesota, December 5, 1958.

At times, the diagnosis of gout may be difficult to make, but more often it is completely overlooked. Clinical characteristics are most important in making a diagnosis. An elevated uric acid in the blood serum is confirmatory but not diagnostic. Therapeutic response to colchicine is of diagnostic value. Twenty per cent of relatives of gouty patients have elevated uric acid but only one in ten of these may develop acute articular symptoms over a period of twenty years. Thirty per cent of patients have renal disturbances. These facts (and many more) plus a thorough discussion of therapy are to be found in this excellent manuscript.

THE diagnosis of acute gouty arthritis, as well as the prevention of recurring attacks by means of judicious application of the principles of control that are now available, should be the responsibility of the physician practicing general medicine and need not be confined to the internist or to the specialist in joint diseases. Furthermore, scarcely any physician engaged in the general practice of medicine or one of the many specialties is spared the experience of encountering an instance of acute gouty arthritis from time to time. Recognition of the signs and symptoms of a previously undiagnosed case of acute gouty arthritis should result in the prompt institution of measures to alleviate acute distress and subsequently consideration of agents helpful in preventing recurring acute attacks.

Gout and gouty arthritis are not oddities in the practice of medicine. The disease is not a rare one and the greater the awareness of the possibility, the greater the likelihood that the malady will be suspected. The arthritis clinic at the Buffalo General Hospital has been especially interested in gout and gouty arthritis and has taken advantage of this interest in pursuing the various aspects of the malady. Although we have been concerned with two late manifestations of the disease, i.e., critical renal insufficiency and chronic tophaceous gout, respectively, these phenomena have appeared in a small percentage, only, of the patients seen over the years. On the other hand, the major emphasis has been confined to those who suffer neither from critical renal impairment nor from chronic tophaceous gouty arthritis. These comprise the majority of patients in our series.

Until recent years, the tools available to prevent recurring attacks were limited and we were forced, without choice, to concentrate upon the treatment of the acute articular episode. In the post-war years, with the development of new drugs, the pos-

sibility for preventing recurring attacks became factual. At the present time, the ability to prevent recurring attacks, as well as the development of new agents and a better understanding of agents already available for the treatment of the acute episode, have been responsible for a more adequate control of this form of arthritis than any other type of chronic articular disorder.

There are several terms to be defined in this discussion. *Gout* is the basic term without reference to acute or chronic joint distress. It is justified in any individual who has suffered one or more attacks of acute gouty arthritis. The only demonstrable abnormality between attacks in such an individual may be the increased concentration of uric acid in the serum and related disturbances of uric acid metabolism that are detected only by precise and complicated research devices. These devices include the volume of the metabolic pool of uric acid and the abnormal pathways of uric acid, techniques which require complicated chemical procedures with radioactive or stable isotopes. *Acute gouty arthritis* requires no comment at this point. The period between the attacks of acute gout has been designated the *intercritical period.* In recent years, the term *prophylactic period* has been preferred because it emphasizes the value of the regimen which inhibits or prevents recurring acute episodes. *Chronic gouty arthritis* or *chronic tophaceous gout* refers to the layman's concept of the malady but is applicable to a small percentage of patients only. Several decades usually elapse following the first articular episode before the development of this stage. Most important is the observation that gout need not be a chronic progressive disease if current principles of management are followed and the incidence of chronic tophaceous gout should dwindle to clinical insignificance in the years ahead.

The designation, *gouty diathesis* should be abandoned or redefined. We use it only in relation to the phenomenon intimate to metabolic gout.

Coronary vessel disease, generalized arteriosclerosis, gastrointestinal symptoms, cutaneous disorders and other clinical findings sometimes seen in patients with gout, are not believed to be part and parcel of the malady. Their incidence is no higher than in a similar group of non-gouty individuals. The appearance of acute articular symptoms or chronic gouty arthritis sometimes follows a blood dyscracia with a prolonged natural history such as, polycythemia vera, myeloid metaplasia, or chronic myelogenous leukemia, among other conditions. The development of clinical gout under such circumstances has been identified as *secondary gout* by Gutman.[1] The clinical findings may be indistinguishable from the more usual type of gouty arthritis; likewise the treatment is similar and should be enforced in addition to those measures employed for the handling of the blood dyscrasia. Terms *urate* and *uric acid* are used interchangeably in this discussion. The former term is preferred since the acid exists in body fluids in equilibrium with a base. General usage however, supports the retention of the term uric acid. A *uricosuric agent* is one that enhances the excretion of uric acid from the body. Metabolic gout, primary gout or familial gout are synonomous.

Heredity.—Gout is a familial malady and the greater the zeal with which one pursues familial incidence the higher the value. In our series we have obtained a positive family history in three out of four of the afflicted. A positive family history should be of some help in suspecting the diagnosis in a patient with unidentified joint distress. Also, for a number of years we have studied the serum uric acid concentration in relatives of gouty patients. Approximately 20 per cent of the next of kin will have an increased concentration of uric acid in the serum without other clinical or laboratory evidence of gouty arthritis. During the period of more than two decades that we have been collecting familial statistics, the development of an acute articular episode in a non-affected relative with an increased concentration of uric acid in the serum has been less than 5 per cent. The chemical abnormality in non-affected relatives is not viewed with alarm, therefore, and no treatment is suggested until after the first attack of acute gouty arthritis.

There are several items that may appear in the patient with gout prior to the first attack. Uric acid stones have been passed in two instances ten years or more before the first attack of acute gouty arthritis. Transient albuminuria has been reported as well as a modest elevation of blood pressure. Since one patient in seven with clinical gout will pass one or more renal stones during the natural history of the malady, it is not surprising that occasionally a patient will be troubled with this complication prior to the first articular attack. Albuminuria and a modest elevation of blood pressure are observed in a somewhat larger number of gouty patients and in a few instances they may precede the initial symptoms which suggest the diagnosis. The pathogenesis of these manifestations is believed to be related to the basic fault, that is, an increased formation of uric acid by the body and an increased transport of uric acid through the kidneys which insults, to a limited degree, the renal parenchyma.

Mortality.—Mortality data in gouty patients have been held within the bosom of life insurance actuarians with the implied, if not adequately documented, concept that mortality is higher than normal controls. On the other hand, it has been my firm belief that, except for patients with critical renal insufficiency, mortality in gouty patients is not increased. Recently we have reviewed the mortality figures from fifty-four patients who were followed in Boston in the 1930's as well as 114 patients who were seen at the Buffalo Veteran's Administration Hospital between 1948 and 1958. The living and the dead data of these two groups were compared with a controlled series of non-gouty persons. The data were subjected to critical analysis by Dr. Abraham Lilienfeld of the Johns Hopkins School of Public Health. It was concluded that the mortality in gout is not unlike the mortality of the non-gouty control.[2]

Diagnosis

The clinical characteristics of the acute attack are most helpful, in our experience, among the several criteria. I would place greatest emphasis upon the clinical features of the acute episode if I were forced to rely upon one diagnostic feature only. These may be observed by the physician at the time of the attack or they may be recounted in the symptom-free period if the patient has been a critical observer. The cardinal signs of inflammation, redness, swelling, heat and tenderness may be

accompanied by an elevation of body temperature, a leukocytosis and an increase in the sedimentation rate. The acute attack usually develops suddenly in a previously healthy individual, sometimes during the day, but more often during the night. Although the acute attack characteristically is sudden in onset, instances have been observed in which the onset was insidious in development and did not reveal the characteristics that sometimes confuse acute gouty arthritis with a septic joint or a traumatic joint. Partial or complete loss of function of the affected joint or joints in the untreated case is the rule. Rheumatoid arthritis and osteoarthritis, two other types of joint disease frequently encountered in the middle-aged men, are not associated with sudden and severe distress. On the other hand, acute rheumatic fever may simulate acute gouty arthritis and poses a difficult diagnostic problem, particularly in the young male. Either malady may be both migratory and polyarticular. The metatarsal-phalangeal joints of the great toe is the classical joint involved in gouty arthritis and approximately one-half of the patients will experience acute distress in this joint during the initial episode. The bunion joint is exquisitely tender and street shoes cannot be worn with comfort. Inspection of the shoe or slipper may reveal an operation upon the medial aspects or even removal of a portion of this invention of modern civilization, hence, the designation "gouty shoe."

The concentration of uric acid in the serum is of considerable help in diagnosis, but the datum should be interpreted cautiously. Serum rather than whole blood is preferred for the determination. The technical procedure in the biochemical laboratory is not always reliable and unless the biochemist is familiar with the possible sources of error in the determination, a false or equivocal value may be reported. Most procedures utilize the development of color which is subjected to interference by a number of substances. A false, normal value may be reported if a patient has ingested one of a number of anti-arthritic drugs within a forty-eight-hour period prior to the collection of the serum for the determination. It is interesting to note that many anti-arthritic agents, whether prescribed by the physician or ingested at the discretion of the patient as a home remedy, are uricosuric. Salicylates, phenylbutazone, and the adrenal steroids cause depression of the uric acid concentration and confuse the interpretation. Thus, it is desirable to wait forty-eight hours after the administration of any analgesic or any anti-rheumatic agent before collecting the serum for diagnostic interpretation.

Colchicine is the only specific anti-gout agent that has no recognized effect upon uric acid metabolism. One need not, therefore, withhold colchicine before collecting serum for chemical analysis. The upper limit for serum uric acid in males is 5 mg. per 100 ml. and the lower range for gouty males is 6 mg. In females this range may be slightly lower and clinical gout has been observed in females with a serum uric acid level not greater than 5.5 mg. It should be noted also, that a few non-gouty persons may have a serum uric acid level in the gouty range. The incidence of such hyperuricemic non-gouty males is sufficiently high to justify caution in basing a diagnosis largely upon the concentration in the serum. The serum level should be used to confirm a clinical presumptive diagnosis rather than to establish the diagnosis in the absence of characteristic clinical features. Save for the abstinence from anti-rheumatic agents there is no ideal time, in relation to acute symptoms, to collect the serum for the determination. There may be slight fluctuations in the level of uric acid in the serum of gouty patients but in the main it can be assumed that if the patient is suffering from gout the concentration of uric acid in the serum will be elevated before the attack, during the attack and after the attack.

Roentgenographic changes, save for soft tissue swelling, should not be expected until after the disease has been evident clinically for a number of years. It is believed that a significant quantity of uric acid must be deposited in bone or cartilage before roentgenographic changes appear. Such findings are characteristic of the well-developed stage and a number of attacks usually have preceded the development of this diagnostic finding. A similar statement may be made for subcutaneous tophi. It is unusual, in our experience, to find tophi in the ears or tophi in periarticular areas at the time of the initial episode.

The use of colchicine as a diagnostic as well as a therapeutic tool has great merit. When a presumptive diagnosis of gouty arthritis is entertained, it is unnecessary to wait for the laboratory to report the serum uric acid level or the interpretation of the x-rays of the affected parts. Specific therapy should be instituted without delay if gout is suspected. Colchicine is the only specific anti-gout

agent and has no recognized action in other types of joint disease. The response to colchicine whether given orally or intravenously may be extremely valuable in confirming the diagnosis as well as in alleviating joint distress. Colchicine should be prescribed orally, 1 mg. every two hours, until the onset of nausea, vomiting or diarrhea. It is imperative to prescribe a full course of colchicine up to the point of gastrointestinal irritation, irrespective of whether diagnostic or therapeutic aid or the combination is sought. Usually the side action is apparent after the ingestion of not more than from 4 to 6 mg. of colchicine. It is equally important that the drug be discontinued at the first sign of gastrointestinal irritability, at which time a gastric sedative, tincture of paregoric, is prescribed and repeated every hour, as indicated. If intravenous colchicine is preferred 2 mg. of colchicine may be given at three-hour intervals for two or three doses with similar results upon joint distress without undesirable gastrointestinal features.

Precipitating Factors.—Although a number of precipitating factors have been implicated in the acute articular episode, we have no knowledge regarding the exact mechanism of the distress. Infiltration of cartilage and subchondral bone by urates surely precedes the first attack. Once the joint structure has been invaded the urates persist save for prolonged administration of uricosuric agents.[3] The possibility of an acute attack meanwhile is ever present. Increased precipitation of uric acid crystals preceding or during the acute attack has not been proved. Probably the precipitation is no greater during the acute attack than at other times. The polyarticular nature of many of the severe bouts suggest a systemic disturbance rather than an exclusively local one. Except for secondary changes attributed to inflammation, the physical appearance of articular tissue at the time of the acute attack is believed to be similar to that in the intercritical period. Nor is the pathogenesis of the acute attack in secondary gout dissimilar from familial gout. When uric acid crystals are present in articular structures, the possibility of an acute attack is present: why, we do not know. Trauma to a joint, mild or severe is a common precipitating factor. The diagnosis of a strain or a sprain is more apt to be entertained than that of acute gouty arthritis. If the knee is the joint affected a large synovial effusion is a real threat. It is our practice in patients with known gout to treat a strain or sprain, irrespective of whether it follows injury as if it were an attack of acute gouty arthritis. The results have been rewarding and not disappointing.

The incidence of acute gouty arthritis following a surgical procedure, mild or severe is significant. Because of the incidence of postoperative gouty arthritis it is our practice to recommend 1.5 mg. of colchicine daily, three days before the surgical procedure and three days postoperatively. If the operation is a major one, colchicine is administered intravenously following surgery. Other precipitating factors include over-indulgence in food and alcohol, an acute infection, minor or major blood loss, emotional trauma and exposure to the elements. There are several drugs that deserve mention as precipitating agents, usually when administered intravenously. These include penicillin, the B vitamins and mercurial diuretics.

Pathogenesis.—The pathogenesis of the metabolic defect in gout is believed to be on firm ground as a result of investigations during the past decade. The increased concentration of uric acid in body fluids and the increased excretion in the urine in a limited number of patients is believed to be caused by an increased formation by the body. The destruction by the human organism of significant quantities, by an enzyme system including uricase, is not of sufficient magnitude to explain the metabolic findings. The concentration of uricolytic ferments in human tissue is not high; nor has diminished excretion of urates by the kidneys been substantiated by unequivocal data.

Dr. Bishop of our laboratory[4] has recently reviewed renal excretion data collected from several laboratories. He has concluded from this review that a renal component cannot be excluded. If there is impaired excretion by the kidneys in gouty patients, there must be tubular excretion of uric acid as well as tubular reabsorption. The former has not been proven but an open mind must be maintained regarding this possibility. Renal clearance studies of uric acid remain normal except in the terminal stages of a minority of patients who have renal insufficiency late in the course of the disease. Most of the afflicted, irrespective of the stage of the disease, show a normal clearance of uric acid and do not show a general or selective inability to excrete this substance. It is believed

that kidney involvement, when it does appear, is secondary to the metabolic fault and is not intimate to the primary dysfunction. The increased formation hypothesis appears to have most data to support it. A few patients with gout will excrete from twice to fourfold the quantity of uric acid in the urine when comparison is made with the non-gouty control.[5] This suggests an increased formation of uric acid by the body. The non-affected relatives[6] with an increased concentration of serum urate provides additional evidence. Lastly, convincing support has come from investigators in several laboratories who have demonstrated an increased formation of uric acid in gouty patients using glycine labeled with radioactive or stable isotopes.[7]

Blood Dyscrasias and Gouty Arthritis.—The number of blood disturbances that may be responsible for clinical gout is considerably higher than I had assumed prior to a review of the literature and a critical analysis of the patients in our series.[8] The development of clinical gout in patients with polycythemia vera, chronic myelogenous leukemia and myeloid metaplasia has been described in the literature repeatedly. The clinical course of the blood dyscrasias usually has been a long one. The increased turnover of nucleic acids with increased concentration of uric acid in the serum has been held responsible. There are two features in secondary gout that are increased when comparison is made with those suffering from familial gout. The incidence of uric acid stones is higher as well as the concentration of uric acid in the serum. In each category, the aberrations are related to increased turnover of nucleoproteins. The highest serum uric acid values, in our experience, are observed in patients with a blood dyscrasia. Values in the 20's and 30's are not unusual; we have observed a few patients with a serum uric acid level greater than 40 mg. per 100 ml. The incidence of blood disturbances in our series is slightly more than 5 per cent. This value should serve to emphasize a critical scrutiny of the possibility of an underlying blood disturbance in any patient with gout, particularly the patient with a serum uric acid concentration above 10 mg. Also, in the very young patient, a blood disturbance may be responsible for the development of clinical gout. In the late 1920's and early 1930's when whole liver was used in the treatment of pernicious anemia, a number of cases of gout were revealed. Other disorders that have been associated with secondary gout include; thalassemia, multiple myeloma, Waldenstrom's hyperglobulinemia, sickle cell anemia, Hodgkin's disease, reticulum cell sarcoma, lymphatic leukemia, giant follicular lymphoma, chronic erythronoclastic anemia and lead intoxication.

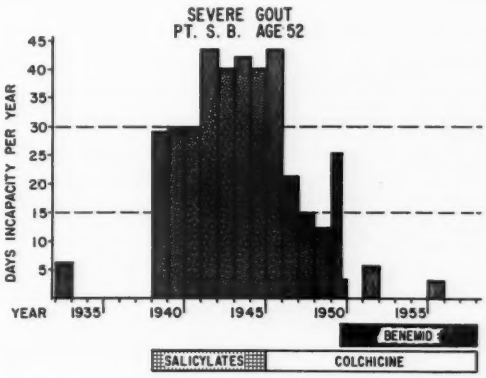

Fig. 2. Incidence of acute attacks of gout over a period of twenty-five years.

Treatment

Colchicine is the drug of choice in the acute attack, irrespective of whether the diagnosis has been confirmed or is merely suspected. It is our practice to prescribe a "full course" of colchicine as noted previously under diagnosis. If the diagnosis has been established and one does not seek confirmation, the treatment of the acute attack may be modified by the prescription of sub-maximal doses of colchicine combined with one of two general anti-arthritic agents. If less than the full therapeutic amount of colchicine is prescribed, (3-5 mg.), 400-800 mg. of phenylbutazone may be recommended daily for two or three days. There are some rheumatologists who prefer to use phenylbutazone, exclusively, in the management of the acute attack. In such circumstances, from 400 to 800 mg. of the preparation is prescribed daily for two or three days. If the acute attack has been untreated or poorly treated for one or more days, more rigorous medication is indicated. In addition to a full course of colchicine, supplementary phenylbutazone or supplementary ACTH is recommended. If the latter agent is prescribed, from

60 to 80 units of ACTH-gel is given for two days. Intravenous colchicine also has a limited but definite place in treatment. During convalescence from acute gouty arthritis, early ambulation is urged. There are no other specific measures recommended for the treatment of the acute episode. General measures include consumption of an abundance of fluid, protection of affected joints, and a diet to suit the patient's wishes.

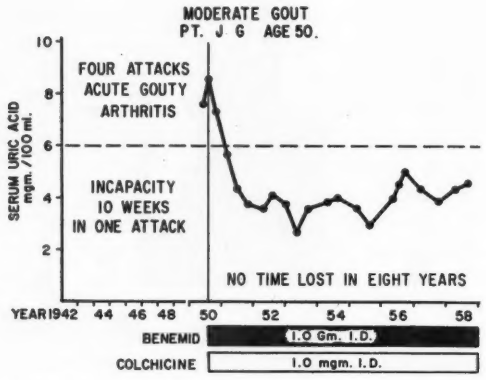

Fig. 3. Effect of the prophylactic regimen upon incidence of acute attacks of gout.

The interval between attacks varies considerably. Several years may elapse in a person mildly afflicted. The patient with moderate or severe gout may experience several attacks per year if adequate treatment is not recommended. Patients who develop tophi sometimes represent a more severe form of the malady and are prone to suffer a higher incidence of acute attacks and greater incapacity per year unless prophylactic therapy is followed. On the other hand, there are some patients with chronic tophaceous gout whose disease appears less critical than during the early stages. Between the acute attacks, in patients without articular deformities, there are no subjective symptoms or objective findings save for the chemical abnormalities in the body fluids. The prophylactic regimen recommended for the inter-critical period embodies the combination of colchicine and a uricosuric agent with excellent clinical results. The majority of gouty patients are eager to follow the regimen and, in return, are permitted to live normal lives and pursue a gainful occupation. An optimistic prognosis was expressed a number of years ago through the prophylactic use of colchicine daily.[6] The future for gouty patients has been further enlightened by the development of uricosuric agents. The one that we have had the most experience with has been probenecid. This powerful pharmacologic agent was designed to inhibit the excretion of penicillin from the body. It was noted initially that it was endowed with uricosuric properties as well. Probenecid has been available for more than eight years and the longer the drug is used, the more convincing the clinical observations and the greater the reliance placed upon it. Furthermore, the toxicity of the drug is low, probably not greater than is observed in the use of pharmacologic quantities of salicylates.

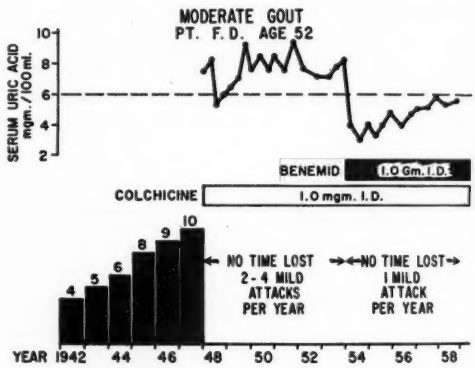

Fig. 4. Incidence of acute attacks of gout as a function of medication.

If the prophylactic regimen is respected, acute attacks should be infrequent in incidence and the patient should be symptom-free save for possibly a few days per year because of minor articular distress. Although the acute episode is a miserable affair if allowed to reach full proportions, proper respect for prophylactic agents will reduce the incidence of acute bouts to clinical insignificance and will either stay or reverse the previously progressive efforts of the disturbance of uric acid metabolism. The value of the combination of two drugs in the prophylactic regimen has been amply substantiated. Colchicine used with a uricosuric agent gives a complimentary effect. There is no overlapping of pharmacologic action. Neither one by itself is as effective as is the combination. Other anti-gout agents may be disregarded if colchicine and a uricosuric agent of low toxicity are taken

daily. Although no effect upon uric acid metabolism has been ascribed to colchicine, the daily use of this preparation in the prevention of recurring attacks has been proven by experience. It is believed to be a sound practice for each patient with moderate or severe gout to take some colchicine daily. If the patient suffers not more than one acute attack per year, one tablet of colchicine 0.5 mg. is recommended daily. Patients severely afflicted are advised to take two or three colchicine tablets each day of the year. Those with chronic tophaceous gout and frequently recurring attacks of acute gouty arthritis, are advised to take colchicine daily up to the point of gastrointestinal tolerance. In some patients this may be as many as four tablets per day. The incidence of acute attacks was reduced significantly through the prophylactic use of colchicine prior to 1950. Since then, a significant further reduction in the incidence of acute attacks and an improved state of well-being has been ascribed to the addition of a uricosuric agent. Tolerance does not develop to colchicine when taken daily and if a full course is needed to combat acute symptoms, irrespective of previous prophylactic ingestion, the pharmacologic action may be demonstrated. A number of patients in our series have taken colchicine daily for more than twenty years; a larger number have taken this drug daily for a decade. No delayed effects or untoward, undesirable actions has been demonstrated.

The addition of a powerful uricosuric agent, probenecid, to the prophylactic regimen in 1950 enhanced the value of colchicine. Our clinical experience has been satisfactory with a dosage of probenecid of 1 gm. daily for the moderately severe patient. The patient mildly afflicted may obtain thoroughly satisfactory results with 0.5 gm. of probenecid daily. No attempt is made to titrate probenecid dosage with levels of uric acid in the serum. There is sufficient fluctuation of the concentration of serum uric acid to make titration unreliable. The above-noted rule of thumb has been proven by experience to be thoroughly satisfactory. Essentially the same number of probenecid tablets are taken daily as colchicine in the mild or moderately severe case.

Rigid restrictions upon habits, good or bad, are not imposed. The patient is encouraged to eat a balanced diet, drink an abundance of fluids, and pursue any physical activity that suits his fancy. Only those items high in purine substances, such as liver, kidney, sweetbreads and anchovies are prohibited. An occasional patient may note a worsening of the disease process following the ingestion of a particular item of food. Under such circumstances the implications are obvious. Otherwise, a balanced diet is recommended. A high fluid intake is necessary in order to provide for the increased excretion of uric acid in the urine under the influence of a uricosuric substance. Since the solubility of uric acid in the urine is near the upper limit of normal, an augmented uric acid excretion should have a similar increased amount of fluid available for transport. Alcoholic beverages are permitted in keeping with the social practices of the afflicted.

The patient becomes neither tolerant nor intolerant to probenecid. The increased loss of uric acid from the body following ingestion of probenecid persists so long as the drug is taken. When the agent is stopped, there is a prompt return to the pre-probenecid level with the reversion of the serum uric acid concentration. This does not imply that the benefits during probenecid therapy have been nullified, but rather that the disturbance is a chronic one and with cessation of ingestion the re-accumulation of urates in tissues begins anew. The toxicity of probenecid is low. It was our impression, originally, that there was a slightly increased incidence of acute attacks during the first few weeks or months after beginning the drug. This impression has not been confirmed with a longer experience. Neither bone marrow depression nor liver damage has not been reported. A few instances of hypersensitivity have been observed. Usually this phenomenon may be corrected with administration of appropriate anti-histaminic agents. The incidence of renal stone in patients with gout, irrespective of the administration of a particular uricosuric agent, is significant. In our series, however, the incidence of renal stones has not increased with adherence to the prophylactic regimen. Comparison has been made of the incidence of stones over a seven-year period on probenecid with a similar period prior to 1950. The incidence in each series is essentially the same —17 per cent. Probenecid is a mild gastrointestinal irritant if taken in full therapeutic amounts on an empty stomach. Such distress may be prevented by the ingestion of the drug with meals or the concomitant ingestion of a mild gastric sedative.

A number of patients have been on probenecid and colchicine daily since 1950, who recounted a previous history of moderate or severe gouty arthritis and had lost weeks or months from work each year prior to the institution of the therapeutic regimen. In recent years they have suffered little or no incapacity from gout. A majority of our patients, irrespective of the severity of the disease, average less than one day per year of incapacity because of acute articular distress. This represents a striking change from the period before the institution of the regimen. It should be appreciated that probenecid is of no immediate value during the acute articular bout. When such an event develops, it is unimportant whether probenecid is omitted or not for a few days. It should be resumed, however, once the acute distress has subsided.

The length of time that a patient should be on the combined regimen has not been determined. It is our prediction that patients severely afflicted with gout will remain on probenecid and colchicine daily throughout the natural history of the disease. Those persons moderately or mildly afflicted are permitted considerable freedom. Patients with moderate gout may revert to a somewhat lower dose-schedule per week after the recommended quantities have been taken regularly for two or three years. Since the escape from probenecid is rapid, a person moderately afflicted should not remain off of the uricosuric agent for any significant length of time. Gout is a chronic disease and the disturbance of uric acid metabolism persists as long as the patient lives. The threat of an acute attack remains because of the continuing increased formation of uric acid by the body.

Summary

There are several features of gout and gouty arthritis that have been stressed in this presentation. A presumptive diagnosis of acute gout should be entertained in any unexplained acute inflammation of one or more joints, particularly in a man. The family history regarding the malady is significant as is the number of relatives of gouty patients having no clinical history of gout but who are found with an increased concentration of uric acid in the serum.

The clinical features of the acute attack, which embody cardinal signs of inflammation, are probably the most helpful criteria in the diagnosis. Confirmation rests upon the prompt response to a full course of colchicine and probably the revelation of an increased concentration of uric acid in the serum. The pitfalls of relying upon the concentration of serum uric acid, alone, has been discussed. Roentgenographic evidence in the earlier years of the disease may be confined to soft tissue swelling at the time of the acute attacks. The finding of the classical "punched-out" areas in the subchondral spaces is a late—not an early—manifestation of the malady.

The pathogenesis of the acute episode remains to be determined. The pathogenesis of the underlying metabolic disturbance is concerned largely with the increased formation of uric acid by the body. Diminished destruction is not believed to participate. Impaired excretion by the kidneys has been the subject of considerable attention over the years and probably does not play a major role. This mechanism may contribute to a minor degree, however.

Participating factors should be appreciated. These include: surgical intervention, an acute infection, local trauma, emotional stresses and selected drugs administered parentally.

The mortality in gout was not abnormal in two series of patients followed for as long as twenty-five years. The prognosis is excellent if the prophylactic regimen is accepted. This involves colchicine and a uricosuric agent (probenecid) administered daily for moderately or severely afflicted patients and less often to those mildly afflicted.

In substance, gout and gouty arthritis are amenable to management with currently available therapeutic agents.

Early Diagnosis and Treatment of Rectal and Sigmoid Colon Neoplasms

● With the experience at the University of Minnesota Cancer Detection Center as a starting point, the authors discuss techniques for detection and treatment of the small and early neoplasms of the lower large bowel.

LLOYD F. SHERMAN, M.D.
ROBERT J. TENNER, M.D.
Minneapolis, Minnesota

Read before the Clinical Meeting of the American Medical Association, December 3, 1958.

CANCER Detection Centers at the various medical centers in this country, have now been in operation long enough to yield statistics which should convince even the most skeptical critic that a similar program of detection is a "must" in every general physician's office. The University of Minnesota Cancer Detection Center[1-3] has been in operation ten plus years. During this period, approximately 9,000 patients have received 31,000 examinations. In the actively examined group, 288 cancers have been found. The instance of precancerous lesions is 55.6 per cent. The over-all survival rate of patients whose cancers were found at the center is 68 per cent. Survival in the asymptomatic group is 76.9 per cent, while that in the symptomatic group is 53.2 per cent.[4] In lesions of the gastrointestinal tract, there is approximately a three-fold increase in survival of the presymptomatic group over the symptomatic group.[1,5,6] Surely no physician can deny his patients the advantages of early precancerous and cancer detection after reading these figures.

TABLE I. PRECANCEROUS LESIONS
(University of Minnesota Cancer Detection Center, 1957)

Rectal and colon polyps	2,386
Leukoplakia	589
Senile keratoses	573
Irritated pigmented nevi	394
Thyroid adenomas	240
Kraurosis vulvae	57
Gastric polyps	39
Vocal cord polyps	1
Total	4,279
Total patients	8,229

The most prevalent precancerous lesions reported by the various centers are *adenomatous*

polyps of the rectum and colon. The various incidences reported range from 10 to 15 per cent of those patients examined over the age of forty-five years.[5] The proctosigmoidoscope is, of course, the means of establishing these lesions. Most general physicians should master the technique of its usage because the rewards will be great in the number of precancerous, as well as cancerous, lesions that they will pick up and in the personal satisfaction that they will gain by giving their patients a more thorough examination. Every patient forty-five years of age or older should be given the benefit of a proctosigmoidoscopic examination regardless of symptoms if he requests a thorough physical examination. In fact, physicians should take it upon themselves to recommend this examination more frequently to members of this age group since 75 per cent of the benign and malignant colonic lesions can be visualized with the 25 cm. sigmoidoscope.

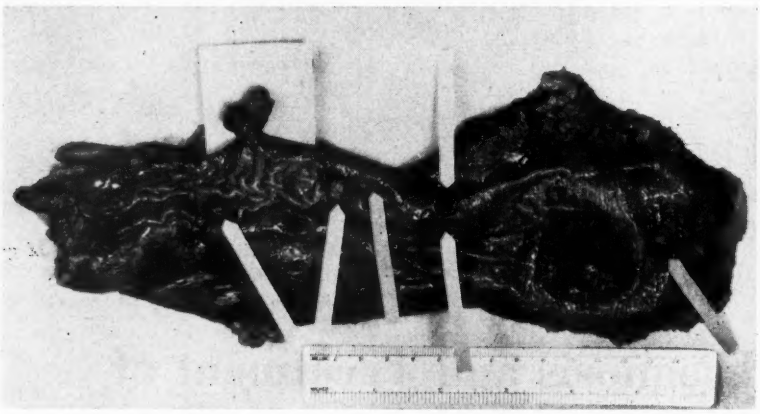

Fig. 2. Polypoid adenocarcinoma of the sigmoid colon with adjacent adenomatous polyps.

TABLE II. PROCTOSCOPY AIDS

1. A clean bowel is essential. The use of any of the hypertonic solution enemas the night before and morning of examination usually produces a clean bowel with a minimum of effort for the patient. Most patients are starved the day of examination.
2. Do not advance the scope unless you can see the bowel lumen.
3. Lift scope with left hand to straighten the lower sacral curve of the rectum, and withdraw slightly to look for lumen when in the blind rectosigmoid pouch.
4. Concentrate on advancing scope painlessly without air, if possible; examine bowel carefully with air inflation as scope is withdrawn.
5. Do not attempt to scope to the "hilt" those patients with fixation and angulation. Remember large diverticulae can be perforated with air inflation.

There are some hazards in the use of the proctosigmoidoscope of which the examiner must be aware of: namely, bowel perforation and undue traumatization of the bowel. Here it might be well to mention several aspects of the technique of performing an uncomplicated examination.

Adenomatous polyps have a characteristic appearance (Fig. 1). Their exact nature may be established by biopsy. The most frequently confused lesions among the small adenoma group are small submucosal nodules, usually lymphoid aggregates, and early carcinoid tumors. These lesions are of rather infrequent occurrence but must be suspected when there is any slight variation from the usual appearance of an adenoma. A recent survey of 1000 adenomas 4 mm. or less in diameter reveals the histology in every instance to be benign. However, five of the lesions were reported as carcinoids. The lesions were biopsied by resident physicians who reported them grossly, as adenomatous polyps. However, I am sure that it would have required the eye of an experienced proctologist to call them otherwise. Early carcinoids do appear much as submucosal lymphoid aggregates with fairly normal mucosal surfaces. We feel justified in destroying small adenomas of the rectum and sigmoid colon by electrofulguration without biopsy if the lesion is 2 mm. or less in diameter.

Rarely will carcinoids be included in this group; however, fulguration is adequate treatment at this

stage of their growth. Troublesome bleeding may interfere with fulguration of these small lesions if biopsy is attempted first. If there is any doubt as to the benignancy of the adenoma, as may be the case with the inexperienced examiner, he should by all means biopsy the lesion first and complete the destruction of it with fulgurating current at a subsequent visit. It might also be wise to advise the beginner at electrofulguration to limit his activity to the posterior wall of the rectum or the area below the peritoneal reflection until he calibrates his machine in the extent of tissue destruction. Remember bowel perforation by electrofulguration is always a possibility, particularly when followed by a procedure that produces increased intracolonic pressure, such as enemas and barium enema studies, even as late as two to three weeks after the fulguration. By all means avoid barium studies for at least a three-week period after fulguration of even the 1 to 2 mm. adenomas.

If multiple polyps are visualized at proctosigmoidoscopic examination, an air contrast barium enema should be ordered prior to fulguration. These patients are best handled in the hospital (Fig. 2). Pedunculated polyps and larger sessile lesions below the peritoneal reflection are generally quite amenable to excision with the fulgurating snare. This is a tremendously valuable instrument in the hands of an experienced operator. We have excised large pedunculated polyps 40 cm. from the anal verge and have similarly removed large sessile villous papillomas that encircle more than one-half the bowel with this instrument, but, of course, not without some trepidation. However, we can see no excuse for performing a colotomy with the open bowel excision of a polyp that is located below the 30 cm. level when a proctologist, experienced in snare fulguration, is available for consultation. Not infrequently, higher lesions can be extracted when the sigmoid colon can be straightened to allow the passage of a 40 cm. sigmoidoscope. The fulgurating snare is useful in the doctor's office for the excision of smaller pedunculated polyps and may also be used to obtain liberal biopsies of vascular carcinomas.

Congenital polyposis of the colon is an entity deserving detailed discussion elsewhere. However, once the diagnosis is established from the history, the air contrast barium enema studies and the sigmoidoscopic appearance of the distal colon (studded with from a score to literally thousands of adenomatous polyps), then the tedious job of preparing the rectum for ileal anastomosis can be undertaken. This in our experience should be done over a period of time with several office visits. At each visit the patient must be cautioned as to the precancerous possibilities of the rectal polyps and a strict plan of follow-up observation should be emphasized.

Fig. 3. Large villous papilloma of distal rectum removed for biopsy by local excision. Serial sections, histologically benign.

Villous papillomas and carcinoid tumors are the next most frequent benign lesions involving the distal bowel. However, both lesions possess malignant possibilities which must be considered foremost. A villous papilloma is an insidious lesion; one-third of these are malignant at the time of the first discovery. The malignant papillomas are usually low grade, histologically, but frequently have been observed to reoccur many years later as highly malignant mucinous carcinomas with fatal prognoses. So these lesions must be treated initially as any other adenocarcinoma of the bowel[7] (Fig. 3).

The villous papilloma is a soft, shaggy tumor with rather ill-defined edges, attached by a broad base and extending usually over a wide area. This lesion is characterized by the copious mucus that it produces. Some patients may give a history of discharging literally cups of mucus each day.[8] This lesion is quite soft to palpation and is capable of secreting considerable mucus even with digital pressure. On proctosigmoidoscopic examination, it is usually polypoid in appearance, fre-

quently possessing villous like projections. Repeated biopsies may be reported as benign until finally a more firm area of the tumor may prove positive if malignant degeneration has occurred. Since multiple sections are frequently required to rule out malignancy, in these lesions, the only acceptable and safe method of approach is the total excision to produce the entire tumor for the pathological study.

Villous papillomas below the peritoneal reflection may frequently be excised with the fulgurating snare. If proctoscopic visualization and digital palpation indicate a firm lesion in part or its entirety, with some granular surface changes, the examiner should strongly suspect malignant changes and take deep biopsies from the most suspicious areas. Should these prove positive, then an abdominoperineal resection or a "pull-thru" procedure, depending upon the level of the lesion, is indicated.[2] Should these biopsies be reported as benign, then the entire lesion should be excised with the fulgurating snare for further study. If no malignant elements can be found, a snare excision may be considered as adequate treatment. However, recurrences are common and the patient should be so advised and followed accordingly.

When large villous papillomas occur above the peritoneal reflection, snare excision is a more hazardous procedure. The smaller lesions may be excised by this method. Larger lesions should be removed in their entirety and this is best accomplished by an anterior resection. We no longer feel that the multiple biopsy and fulguration technique is safe therapy, since isolated areas of malignancy may be missed. The pathologist must have the entire lesion.

Carcinoid tumors of the rectum have been largely overlooked until recently. The first case was reported in the literature in 1912; only five additional cases were added to the literature in the next thirty years, but the past decade has witnessed the recording of well over 100 cases of rectal carcinoid. All investigators are now in agreement that carcinoid tumors are malignant, although characteristically slow in growth and metastasis.[1,9,10] Even after the disease has spread to the lymph nodes and other parts, it may produce little or no effect upon the patient for a period of months or years. A little more than 10 per cent of rectal carcinoids have developed metastasis, a figure which exceeds that for similar growths of the appendix, but is only about one-fourth as great as that for carcinoids elsewhere in the gastrointestinal tract. The favorable position held in this regard by appendiceal and rectal cardinoids appears to rest mainly on circumstances leading to early surgical intervention.[11,12]

Small carcinoids of the distal colon within reach of the sigmoidoscope are subject to visual scrutiny, and may be suspected to be other than adenomatous polyps if they have the appearance of a submucosal nodule with normal mucosa overlying the excrescence. As these lesions increase in size, the mucosa is invaded to give a granular appearance; subsequently, the lesion may be ulcerated and stenosing—much the same as any scirrhous adenocarcinoma. Since it is our policy to biopsy all polypoid lesions greater than 2 mm. in diameter, whether they are mucosal or submucosal in origin, we feel that by so doing we will pick up the carcinoids with invasive tendencies. The treatment of small carcinoids is still somewhat controversial.[12] Our rule has been as follows: if the lesion is greater than 4 to 5 mm. in diameter and has a tendency toward invasion of the submucosa and muscularis, then we feel that a resection of the involved segment is indicated. Smaller noninvasive lesions can be safely treated by electrofulguration.

The subject of carcinoid tumor cannot be abandoned without mentioning the interesting evidence that secretions of these lesions produce increased blood levels of 5-hydroxytrytamine which in turn is thought responsible for the carcinoid syndrome. This syndrome which occurs only in carcinoid patients with metastases, consists of episodes of flushing that may last seven to eight minutes, plethoric facies, diarrhea and edema of the legs. Many of these patients will have sclerosis of the valves of the right heart; even so, the prognosis may not be necessarily bad and some of these patients have lived for a number of years.[13]

Adenocarcinoma is by far the most prevalent malignant lesion of the distal colon. The diagnosis is relatively simple, if one is alert to the cardinal symptoms of bowel cancer. Silent, asymptomatic, lesions do definitely occur, but the great majority (98 per cent, University of Michigan Series)[14] of patients with adenocarcinoma of the rectum and sigmoid colon will give a history of one or more of the following symptoms:

1. *Bleeding.*—This is usually bright red but may be dark and mixed in with the stool.

2. *Change of bowel habits.*—A careful history may not reveal any actual change of bowel habits until late in the course of the tumor's development. Early, many patients may have a sensation of urgency and pass more flatus than usual, accompanied by mucus. Often such a simple clue will lead an astute examiner to a diagnosis.

3. *Pain.*—Rectosigmoid lesions may compromise the bowel lumen early to give rise to crampy abdominal pains preceding defecation. This is more infrequent with rectal lesions; however, many of these patients may complain of low backache and tenesmus as the lesion approaches the sphincter.

A positive history of one or more of the above symptoms should be reason enough to institute the diagnostic triad to rule out bowel malignancy:

1. *Digital examination* will reveal that nearly 50 per cent of these lesions can be palpated by a 10 cm. examining finger.[3] At this point the examiner should also satisfy himself as to the degree of local extension and fixation; if the tumor is palpable, one can learn a great deal about its nature by simple palpation.

2. *Proctosigmoidoscopic examination* with a 25-cm. scope will demonstrate that over 75 per cent of the colonic carcinomas arise in the distal colon.[3] Lesions above the reach of the examining finger can be carefully palpated with the end of the scope to yield some information as to its fixation. Biopsies should be taken at this stage of the examination and they should be multiple and from various areas of the tumor. With a little experience, the occasional examiner will learn the characteristic appearances of adenocarcinomas, whether they be polypoid or ulcerative with rolled edges, and his impression by actual visualization is a very important clue in the establishment of the diagnosis. At this point the level of the lower margin of the cancer should be measured and recorded for consideration by the exploring surgeon in selecting the operative procedure of choice.

3. *Air contrast barium enema studies* should always be ordered unless the lesion is nearly obstructing in nature, particularly, to rule out second primary neoplasms and polyps elsewhere in the colon. It is estimated that one-third of the patients with rectal and colonic cancer will also have adenomatous polyps located elsewhere in the bowel.

Moynihan[15] made the significant and often quoted statement that, "Surgery of malignant disease is not a surgery of organs, it is the anatomy of the lymphatic system."[13] Nowhere is this more applicable than to the malignant lesions of the rectum and colon. Since the introduction of the classical abdominoperineal excision by Miles in 1908,[16] this operation has become established as the standard procedure for removing rectal cancer.

Miles described three directions of lymphatic spread of cancer of the rectum and distal sigmoid colon,[17] namely, the *upward* or *superior* avenue of metastases along the course of the superior hemorrhoidal vessels; a *lateral* avenue of spread eventually terminating in the iliac lymphatics; and the *downward* or *retrograde* avenue of spread below the level of the tumor.

For our own satisfaction we have verified these avenues of metastases with the *in vivo* injection of a vital dye (Direct Sky-Blue, used with hyaluronidase-Wyeth). Dye spreads laterally only if injected below the middle valve of Houston (7 to 8 cm. from the anal verge) and then along the course of the middle hemorrhoidal lymphatics in the lateral rectal stalks and not *via* the levator muscle as has been previously described as the site of lateral metastases.[17] Freidin[18] of Australia confirmed this observation and testified that low rectal lesions have a poorer prognosis than those located above the middle valve of Houston due to the opportunity for additional spread of cancer laterally. He was unable to demonstrate any lateral lymphatic metastases when the cancers were situated above the middle valve of Houston. The closer the lesions to the middle valve of Houston (in a caudal direction), the greater the instance of lateral lymphatic metastases. Freidin also showed that lateral metastases could occur without blockage of the superior chain of lymph nodes.

The chief route of metastasis in cancer situated at any level in the rectum is along the superior hemorrhoidal chain of lymphatics. Here, nodes may be involved at any level up to the origin of the inferior mesenteric vessels from the aorta and the vena cava. We are in complete agreement that the Miles (abdomino-perineal) resection is the best operation for cancers of the distal rectum, located below the middle valve of Houston, if the operator is diligent in performing a high ligation of the inferior mesenteric pedicle. We would like to add that the iliac areas should be inspected closely for involved lymph nodes which should be removed if

suspected to be involved with metastases (Fig. 4).

Cancers of the upper rectum (above the middle valve of Houston) do not spread laterally but may involve the superior lymphatics and spread retrograde for a distance of 8 to 10 cm. below the lesion. Retrograde metastasis is not common but may occur. Because of this possibility, we feel that any cancer located below the 12 cm. level should be resected by removing the entire rectum, this can be accomplished best by a "pull-thru" type of resection as recommended by Bacon.[3] Lesions between 7 to 12 cm. level are best suited for this procedure if local extension does not exist. If the surgeon is not experienced in the "pull-thru" procedure, he should then resect the entire rectum by a Miles (abdomino-perineal) resection. We feel that an anterior resection with anastomosis is not a good cancer operation for lesions below the 12 cm. level because of the high recurrence rate due to retrograde metastasis and seeding through manipulation of the lesion.

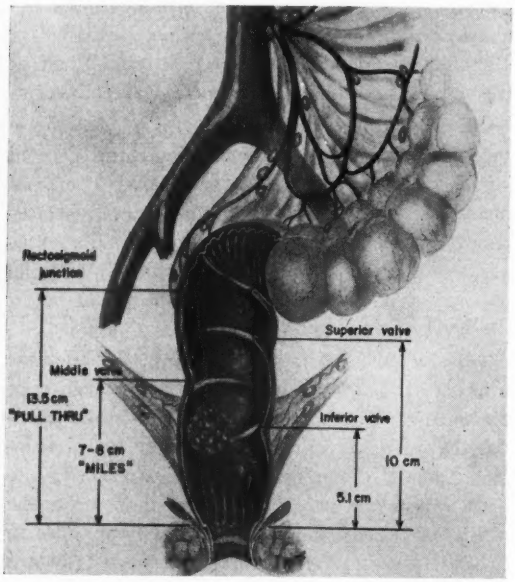

Fig. 4. Lymphatic drainage of rectum and sigmoid colon.

Cancers of the rectosigmoid and distal sigmoid colon above 12 cm. are usually amenable to anterior resection and anastomosis if the operator feels that the bowel can be sufficiently mobilized to get 8 to 10 cm. below the lesion with his bowel transection. We have learned never to promise any specific operation to a patient in advance, and particularly do we avoid promising that he will not awaken from surgery with a colostomy, because often fixation and local extension are much greater at the time of exploration than surmised on examination. However, a surgeon should promise the patient with a cancer of the distal colon that he will perform the best cancer operation that he can for the specific lesion encountered. The final decision can only be made with the abdomen open at the time of surgery.

Summary

1. The adenomatous polyp is the most frequently encountered premalignant lesion of the colon. Electrofulguration and snare excision are the common methods of treatment.

2. Villous papillomas may occur as benign lesions in two-thirds of the patients. Malignancy should always be carefully ruled out by total biopsy of the lesion.

3. Carcinoid tumors of the rectum are malignant and should be treated as adenocarcinomas except for the extremely small (2 to 3 mm.) lesions that can be safely destroyed with electrofulguration.

4. Adenocarcinoma is the most frequent malignant lesion of the colon. Adequate knowledge of the lymphatic drainage of the specific portion of bowel involved with cancer is the key to successful surgery.

Massive Small Bowel Resection

Presented as an Inaugural Thesis before the Minneapolis Academy of Medicine, March 17, 1958.

VIRGIL J. P. LUNDQUIST, M.D.
Minneapolis, Minnesota

SINCE the first successful extensive small bowel resection in 1881 by Koeberle, it has become increasingly more common for surgeons to encounter conditions in which extensive small bowel resection is necessary. It has been stated that a loss of one-third of the intestine was possible with the maintenance of normal weight and strength. Loss of one-third to three-fourths of the small intestine has usually led to a loss of weight and strength and frequent diarrhea. The loss of more than three-fourths of the small intestine has often led to severe merasmus and death of the patient. At the time of Koeberle's first case report, 205 cm. of the bowel was removed. The statistics and case reports in the literature have been somewhat difficult to interpret since there have been various methods of reporting with a note made of the amount of bowel resected on some occasions—on others, the amount of bowel remaining—these figures being either in centimeters or in percentages of the total small bowel. This has led to some confusion in the interpretation of the various reports.

Haymond[1] in reviewing 1161 cases in which the total length was noted at operation or autopsy, arrived at an average length of the small bowel of 21 ft. 6 in. or approximately 650 cm. This has been considered as a relative standard of measurement. As a result, 200 cm. (approximately one-third) of the bowel has been thought to be the starting point for the consideration of massive small bowel resection. This figure, of course, is subject to wide variations depending on the amount of bowel present in the patient. Two hundred cm. would be a relatively small excision in the negro patient reported by Lamb with a total length of small bowel of 1260 cm. or 40 ft.

The statistics have further been confused by the reporting of the successful cases and the absence of reporting of the unsuccessful cases. In Haymond's review of 257 cases of massive resection, the total mortality was 33.5 per cent. From his review, it was determined that a patient could return to normal after a 35 per cent resection of the small bowel. It was thought that a 50 per cent resection was the upper limit of safety. From various reports in the literature it has been well documented that many excisions above 50 per cent have been compatible with a relatively normal existence in several patients.

Etiology

Occasionally in the elective surgical treatment of disease, such as regional enteritis or malignancy, it has become necessary to excise large segments of the small bowel either at one stage or in multiple stage procedures. Usually, however, the massive resection of the small intestine has been performed under uncontrolled conditions and as an emergency procedure. This has often been necessitated in resections where extensive neoplastic disease or when necrotic infarcted gut, due to mesenteric vascular occlusion, has been encountered.

Mesenteric arterial embolism or thrombosis are more common causes of the vascular occlusion than venous thrombosis. The arterial embolism usually follows coronary heart disease or auricular fibrillation. Thrombosis is often the end result of abdominal infections, mechanical obstructions, or severe trauma. The policy of earlier surgical intervention in the cases of mechanical small bowel obstruction has lowered the incidence of mesenteric vascular occlusion as an end result of these obstructions. In Haymond's review in 1935, a large number of cases requiring massive resection of the small bowel appeared in patients with volvulus and with incarcerated or strangulating hernia. Pathologic conditions of the female pelvis (including uterine perforations with a currette) also accounted for a distinguished number of cases in this earlier review. Undoubtedly the improvement in surgical and gynecological technique has lessened this hazard.

Symptomatology of Vascular Occlusion

The early findings in the cases of mesenteric vas-

cular occlusion are often not dramatic. However, in some there is a sudden onset of fairly severe symptoms of upper abdominal pain associated with nausea and vomiting. There may or may not be associated diarrhea early in the course. Occasionally the onset is gradual and insidious and the development of a slightly tender abdomen with minimal rigidity and later distention may occur without the suspicion of the underlying vascular occlusive process coming into mind.[2] Clinically the picture may be acute, severe, and dramatic—as in pancreatitis or perforated viscus—or it may be mild and run a course of several days. The diagnosis should perhaps be suspected in cases with relatively severe abdominal symptoms and minimal physical findings. The diagnosis is rarely made preoperatively which is of some consolation when one opens the abdomen and finds the occluded vessels and necrotic bowel. However, early surgical intervention is mandatory and has resulted in an improvement in the mortality in statistics. For example, in 1938 at the Mayo Clinic, the mortality was 84 per cent in a review of cases to that time, with only 31 per cent being operated upon. From 1938 to 1948 with 54 per cent undergoing surgery, the mortality rate was down to 23 per cent.[3]

What Happens After Massive Resection of the Small Intestine?—The changes in water absorption and the metabolism of various food substances have led to many experimental and clinical studies. Balance studies and absorption studies for carbohydrates, proteins and fats have revealed some interesting if not entirely conclusive results.

Adaptation.—That there is an adaptation of the body to the new digestive program is, of course, obvious. Part of this adaptation of the body takes place by a change in the total weight of the patient. The loss of weight leads to a lower basal metabolic rate and a lower caloric requirement and thus a diminished need for protein replacement. At a certain minimum weight, if the resection has not been too drastic, the decreased nutritional needs are eventually met by the expanding capacity of the intestinal absorption and the weight finally stabilizes. There is also adaptation by the intestine increasing its absorptive capacity. This adaptation occurs in both a functional and an anatomic manner. Within a few weeks there is a slower emptying of the stomach as shown by Stasoff and an increased gastric secretion. The colon has been shown to have an increased capacity to absorb water, electrolytes and amino acids. Unfortunately there is an apparent failure of the colon to absorb fats.

There is considerable anatomic adaptation of the small bowel after massive resection. There is an increase in the size of the lumen and a thickening of the wall of the bowel. This is noticeable on x-ray examinations with a coarsening of the mucosal pattern being present. Microscopic studies in dogs by Monari have shown that the mucous membrane doubles its normal thickness and the villi become larger and more numerous after massive resections. Flint[4] stated there was a 400 per cent increase in the absorptive area of the small bowel by this marked hypertrophy which occurs primarily in the tunica mucosa. Common findings after the massive resection of the intestine have been loss of weight, diarrhea, edema, anemia, loss of fat and protein, lowering of blood calcium and serum protein and elongation, dilatation, and hypertrophy of the remaining bowel.

In considering the changes in water absorption which occur after massive resection, it is remarkable that many times the diarrhea and frequent watery stools have returned to relatively normal within six weeks postoperatively. The colon in some cases develops a remarkable reservoir effect. In one case reported by Jackson and Linder[5] (in which only 6 to 7 inches of proximal jejunum and distal ileum remained between the ligament of Treitz and the cecum), the patient living for three and one half years, had a disappearance of his postoperative diarrhea and returned to one evacuation a day which "would not disgrace an elephant, being up to one-and-one-half gallons." On unrestricted water intakes, it has been found that 90 per cent or more of the feces consists of water. There appears to be little objective correlation of the fluid intake to the frequency of bowel movements or their water content. Subjectively the matter of urgency and tenesmus appears to be better controlled with restriction of oral fluids.

Animal experiments have shown that approximately 50 to 70 per cent of the small intestine could be removed without ill effect. Weight was maintained and protein and fat absorption was not significantly altered. On the removal of the distal 50 per cent of the small bowel, there was profound interference of fat absorption and considerable loss of weight. It has also been determined that the ileocecal valve is of considerable importance

in the sacrifice of segments of bowel, this being particularly true when the distal bowel was sacrificed but of lesser importance with sacrifice of the proximal bowel. Pietz,[6] in his excellent review, has remarked that patients can get along with only one or two feet of small bowel remaining. When there are six feet of small bowel left there is usually normal metabolism and no significant fat losses. Fat, nitrogen, and electrolytic excretions in the stool are less extensive if a segment of ileum, with or without jejunum, the ileocecal valve, and the entire colon is present as compared to a similar length of jejunum alone with a portion of colon being absent.

Carbohydrates.—There is a rapid adaptation for the absorption of carbohydrate. The colon, of course, can absorb fairly large amounts of glucose. The small intestine has been shown to be much more important as a medium of absorption than of digestion. In the study of carbohydrate metabolism in these patients, balance studies have been of little value. Fermentation by bacteria in the colon has made the quantitative studies of the stool sugars and starches very inaccurate in the determination of carbohydrate metabolism. It has been stated that the various food elements should be studied by at least two tests if the absorption method is used.

In following carbohydrate metabolism the absorption tests most often utilized are the oral glucose tolerance test, the oral galactose tolerance test, and the intravenous glucose tolerance test. In following patients with tests to determine the limits of absorption it should be remembered that these are very vigorous and place a full load on the remaining gut at the time of the test. Balance studies are somewhat more realistic. The full capacity of the gut is not necessarily belabored by the balance studies. The absorption studies which are done within a certain time are also less realistic since in balance studies time for absorption is not important and thus more closely resemble the normal condition of the bowel during the twenty-four-hour period. The absorption studies, in other words, make the gut work overtime. The ease of carrying out the absorption studies and lessened activity for overworked laboratory facilities make them very desirable. When the oral carbohydrate tolerance tests have been utilized it is shown that there is very little abnormality in the patients with remaining short intestines.

Proteins.—Protein metabolism in these patients often reaches a relative state of equilibrium. In several cases of massive resection which have been followed, normal serum proteins have been found. However, it appears that a small amount of jejunum is necessary for the absorption of proteins. In Schwartz'[7] case of duodenal mid transverse colostomy, there was an inability of the patient to absorb oral nitrogen and as you will note in one of the cases presented here with only 5 cm. of jejunum remaining, hypoproteinemia was a real problem. The laboratory absorptive tests used in following protein metabolism have been the oral methionine tolerance and glycine tolerance. In a patient with only 90 cm. of jejunum, there was nearly a normal tolerance of both of these tests. In another patient with only 6 to 7 in. of proximal jejunum and distal ileum remaining, the serum proteins were normal until just before death. In using the oral methionine tolerance test in a patient with 13 cm. of jejunum, Althausen[8] showed a 40 per cent tolerance as compared to the control. It has been shown that the colon can adapt itself to absorb fairly large amounts of amino acids. This has been demonstrated by injecting amigen into the colon and measuring the amount of absorption. In animal experiments Kremen and his associates[9] have shown that a high fecal nitrogen loss obtains when the ileum is removed and this is increased when the animal is on a high fat diet with more fat being lost in the stool. Fecal nitrogen excretion has been shown to vary with the volume of the stool and not the volume of the nitrogen intake.

Fats.—The metabolism of fats in patients with massive small bowel resections is an entirely different problem. This is the area in which these patients fail most miserably. Again borrowing from the experience in animal experimentation, it is accepted that the ileum is the primary fat absorption area in dogs. In patients with massive bowel resections steatorrhea has been the major problem. Schwartz has demonstrated that on 100 gm. fat intake the normal individual absorbs approximately 95 gm. and a case of massive small bowel resection absorbs 55 gm. In reviewing several cases with quantitative studies of fat absorption varying figures from 30 to 75 per cent of normal fat absorption is possible. In most of these patients there is an enormous loss of fat in the stool, up to five times normal. There are two types of steatorrhea described by Fowwther: one the defi-

cient fat absorption type in which the split fat is elevated in the stool; the other being the deficient fat digestive type in which the neutral fat is elevated in the stool. In cases with massive intestinal resection, fat remains in the stool owing to poor fat absorption. The increased fecal fat in these patients is not related to stool volume but to fat intake as contrasted with the excretion of fecal nitrogen. That there is some adaptation of the remaining bowel to increase its fat absorptive capacities has been shown by Schwartz in a patient with 90 cm. of jejunum remaining and a jejuno transverse colostomy. In the first month postoperatively there was absorption of 40 per cent of the fat and six months postoperatively there was absorption of 65 per cent of the fat on balanced studies.

In following fat metabolism in these patients, absorption studies as well as balance studies have been utilized. One of the absorption studies is the oral vitamin A tolerance test. In this test, the vitamin A content of the plasma is measured four hours after the oral ingestion of 7,000 International Units of vitamin A per kilogram body weight. A patient of Althausen's,[10] with 15 cm. of jejunum remaining and a jejuno-transverse colostomy showed 8 per cent of the average normal increase in four hours was possible. In another with 90 cm. of small bowel remaining, there was little change in the oral vitamin A tolerance measured at six weeks and twenty months. Another fat absorption test which has been utilized is the so called "butter-tolerance test." In this test, 60 gm. of butter is ingested followed by turbidometric determinations of serum for six hours. By means of this test it appears that there is an increase in the fat absorptive adaptation of the bowel. A patient with 120 cm. of small bowel remaining had 9 per cent of normal absorption in one month and 100 per cent absorption at six months. Another with 90 per cent of bowel remaining had 74 per cent of normal absorption at twenty months.

Unfortunately the altering of the type of diet has not been of much benefit in changing the characteristics of fat absorption. Changing the diet from natural foods to a synthetic type of predigested foods had little effect on the utilization of fats. The addition of papain (which reduces the fecal fat in pancreatic insufficiency) has not been highly beneficial in managing these cases. Neither has the addition of "Tween 80" to the diet.[11] An interesting case was cited by Bothe[12] surviving four years following resection of all but 15 cm. of proximal jejunum and 6 cm. of distal ileum.

This patient was losing fat at a rate three to five times normal in the stool daily but maintained his weight and well-being on a high fat diet consisting of at least two quarts of milk a day, a quarter pound of cheese and a considerable amount of butter.

Calcium.—An associated deficiency these patients often demonstrate is hypocalcemia. This problem is related to the large amount of fat in the stool carrying out with it a large quantity of calcium in the form of calcium soaps. The impairment of calcium absorption is unlikely if 6 feet of small bowel remains. It has been demonstrated that hypocalcemia is a more common occurrence if only jejunum remains. This may be related to the fact that the ileocecal valve is removed if ileum is sacrificed. Tetany has occasionally been a problem in massive bowel resection. The body's stores of electrolytes and calcium are drawn upon.

Electrolytes.—It is true that normal electrolyte balance may not have been a problem in most massive resections. Hypopotassemia was a problem, however, in one of Trafford's cases in which there was an estimated 92 per cent resection, this being one of the most extensive cases reported.[13] It will be noted that hypopotassemia was a problem in the extensive resection reported here.

Vitamins.—The absorption of vitamins is to be noted in managing these patients. The fat-soluble vitamins are lost in great amounts. These patients have a low ascorbic acid level. It is of importance that additional vitamins, ofttimes parenterally administered, be added to their regimen.

Other Changes.—There are other physiologic and psychologic effects which occasionally are encountered in the management of patients of this type. The removal of a large segment of bowel from the body naturally removes a large portion of the vascular bed from the body. In Brezen's case, the blood volume dropped one-third after resecting all but 18 in. of the small bowel, 10 in. of jejunum and 8 in. of ileum.[14] Most of these patients have been shown to have a considerable decrease in their libido following massive intestinal resection. Often they have a change in their normal psyche. This is not unusual when a person

has to alter his entire mode of living to accommodate to his changing absorptive processes and bowel evacuation.

The presence of anemia after massive resection has been challenged by Jackson and Linder. It is their thought that massive resection in itself is probably not the cause of the anemia. They believe that anemia, hypoproteinemia and edema, depression of calcium, and tetany are extremely rare after massive resections and are probably associated with the presence of other conditions. They believe that the "jejuno-ileal insufficiency" of Bennet and Hardwick which leads to a sprue-like syndrome with steatorrhea anemia, edema, tetany and the like, is not the same as the "under-nutrition syndrome" of massive resection. The "under-nutrition syndrome" is characterized by loss of weight, fall in basal metabolic rate, loss of libido, abnormal desire for salt, and maintenance of electrolytic balance by depleting the body stores. It has been advanced that the causative factors of the anemia and the related findings are usually associated with other conditions present with massive excision such as infiltration of the gut with tuberculosis or malignant processes, regional enteritis, gastrocolic fistula, multiple strictures or the "loop syndrome." The "loop syndrome" is described as a natural or surgical production of pockets, pouches, loops or bypasses in the small bowel. This is demonstrated in one of the reported cases with a side-to-side intestinal anastamosis following resection. The features of intestinal insufficiency do occur with remarkable rapidity following this reconstruction suggesting a "toxic" agent as the result of these "loops."

Management.—In the management of these patients, it is, of course, important that the patient be given a diet high in protein and high in caloric value. Frequency of feeding is of benefit. A low fat diet is recommended. Supplemental electrolytes may be important and supplemental vitamins are required. The addition of food supplements and therapeutic adjuvants such as "Tween 80," pancreatin, bentyl, cortisone, and papain, may all have their place. There are no lasting benefits from vagotomy in animal experimentation.[15]

Case Reports

Case 1.—Mrs. V. D., aged forty-four, was admitted to Swedish Hospital (Minneapolis) on February 15, 1957, with the complaint of melena for one-and-one-half days' duration. History revealed that in 1939 the patient had undergone a dilitation and curretage with perforation of the uterus and the onset of mesenteric thrombosis necessitating immediate resection of small bowel with exception of "three feet" of the small intestine. Subsequent to that time, the patient had had recurrent gastrointestinal bleeding evidenced by melena on several occasions occurring every one or two years with no warning signs. In 1949, the patient had gastrointestinal bleeding with hematemsis and a diagnosis of duodenal ulcer had been made by means of x-ray at that time. In 1955, the patient had marked melena and the hemoglobin had dropped to 5.1 gm. The patient had continued to have marked diarrhea with six to eight stools daily since the time of the intestinal resection.

Physical examination revealed no gross abnormalities. The patient weighed 100 to 105 pounds and had a best weight of 110 pounds during one of her pregnancies. The laboratory findings revealed a hemoglobin of 7.9 gm. and a hematocrit of 22 volumes per cent.

The patient underwent surgery on February 19, 1957, at which time there was no evidence of ulceration in the region of the duodenum. Gastrotomy was done and normal findings were encountered. The small bowel measured 41½ in. from the ligament of Treitz to the ileocecal valve. Side-to-side anastamosis which had previously been done in 1939 was encountered "18" inches from the ileocecal valve with large blind pockets, being present. The area involved was resected (4 in.) and an end-to-end anastomasis of the small bowel was done.

The patient had an uneventful convalescence and at six weeks was having one to two stools per day. Thirteen months postoperatively, the patient was again seen and at this time her weight was 115 pounds and she was having one to two stools daily; no diarrhea and no melena had been present since surgery. She had no food dyscrasias and stated that she felt excellent.

Case 2.—Mrs. A. S., aged sixty-five, was admitted to the New Prague Community Hospital on October 30, 1955. At this time she gave a history of having had abdominal pain and distention of one months' duration which had become more severe the night before admission. The patient had had a dilatation and curretage and conization of the cervix for an erosion two months prior to this time and at this time the abdomen revealed negative findings.

Physical examination at this time revealed the presence of abdominal distention and a mass in the mid-abdomen. Blood pressure was 138/90, pulse 84, temperature 99 and the patient gave evidence of recent weight loss. Laboratory findings revealed a white blood count of 40,350, PMN's 90 per cent and hemoglobin 14.7 gm. Other findings were within normal limits. X-ray examination of the abdomen revealed dilated small bowel loops.

The patient was treated by the introduction of nasogastric suction, intravenous fluids and antibiotics and on October 31, 1955, at which time her condition was worsening, her distention increasing even with suction, and the bowel sounds becoming inactive, it was thought wise to give the patient the benefit of abdominal exploration.

Surgery was done and at the time of laparotomy a superior mesenteric thrombosis was encountered with an infarction of the bowel necessitating resection of the entire small bowel from 1½ in. distal to the ligament of Treitz to 4 in. above the ileocecal valve on the ascending colon. An end-to-end jejuno-colic anastamosis was done. A cystadenocarcinoma of the right ovary measuring 20 cm. in diameter was also excised. On later examination, it showed no evidence of a break-through of its capsule on examination. The operating time was one hour and fifteen minutes which is only mentioned to indicate the poor condition of the patient at the time of resection.

Bowel sounds were active on the second postoperative day. The suction was removed on the fifth postoperative day, but was re-inserted two days later because of the development of an intestinal fistula in the abdominal wound. This healed spontaneously in two weeks and remained healed. The patient was maintained on a high carbohydrate, high protein, low fat diet. The weight dropped to 80 pounds from a preoperative weight of 100 to 105 pounds. The patient continued to have two to four stools daily being maintained on two to three oz. of paregoric daily. She developed a severe edema of her legs and marked anemia. On forced feeding, supplemental intravenous administration, serum albumin the patient achieved a maximum weight postoperatively of 89½ pounds, four months following surgery. The patient gradually became worse and expired eight months postoperatively.

Of some interest is the laboratory data which revealed on the eighth postoperative day hemoglobin was 12.1 gm., serum chloride 99.1 mEq. per liter, serum sodium 148 mEq. per liter, serum potassium 4.5 mEq. per liter.

Four months postoperatively, hemoglobin was 12.5 gm., serum proteins 6.6 mg. per cent with a reversal of the globulin and albumin ratio, the globulin 4.8 mg. per cent and albumin 1.8 mg. per cent, serum calcium 4.7 mg. per cent, potassium 3 mEq. per liter and the blood volume studies were hematocrit 29 volume per cent, plasma volume 2.2 liters with total volume 3.1 liters (normal 2.4 to 3.5 liters). Liver function studies and bone marrow examination four months postoperatively were within normal limits.

Discussion

DR. ARNOLD J. KREMEN: I have enjoyed very much Dr. Lundquist's remarks on the problem of "Massive Small Bowel Resections." This is a controversial area and quite appropriately should be a topic for discussion at meetings of groups such as this.

Several years ago, I published a paper ("An Experimental Evaluation of the Nutritional Importance of the Proximal and Distal Small Intestine," Annals of Surgery: September, 1954), reporting an experience in dogs wherein we attempted to define the extent of resection that could be tolerated and to evaluate which areas of the small bowel are most vital to maintaining a normal nutritional state. From these studies, it was concluded that the proximal small bowel could be sacrificed without great nutritional derangement providing 30 per cent of distal small bowel and the ileocecal valve were present. The greatest weight loss and fecal fat loss occurred when the ileocecal valve was by-passed and the distal ileum was lost. With these observations in mind, it has been my experience that most clinical cases surviving massive intestinal resection in a good nutritional state have been those where it was possible to preserve, in the intestinal stream, the very terminal ileum and the ileocecal valve.

DR. N. K. JENSEN: First, I want to say that I have enjoyed Dr. Lundquist's paper very much. He has made an exhaustive search of the literature and has added some interesting material from his own experience. Dr. Donald S. Amatuzio, working at the Jay Phillips Laboratory, on a project that was first started under the auspices of the Cardiac Research Committee of Minneapolis, investigating lipids and relationship to arteriosclerosis, has recently shown that short-chain fatty acids are handled by the bowel much the same as glucose is, and that people with disturbance in fat digestion can handle the short-chain fatty acids very readily. We have recently studied a case with Doctor Amatuzio, a man who had the greater portion of his small intestine, the ascending, transverse and descending colon, resected, leaving him with a little over 7 feet of small intestine anastomosed directly to the sigmoid. This man gained weight, and lost most of his gastrointestinal symptoms on a diet which used coconut oil as a source of fats, coconut oil being made up of short-chain fatty acids. Doctor Amatuzio has also had success in handling celiac disease and other steatorrheas, replacing the long-chain fatty acids in the usual diet with fatty acids of 8 carbon lengths and less.

The "Detached Syndrome" in the Aged

Some Aspects in Management

The "Detached Syndrome" in the aged begets serious problems. Prompt recognition and effective alleviation of this syndrome will help many to grow old gracefully.

ANTHONY R. TORTORA, M.D.
Brooklyn, New York

Dr. Tortora is a Fellow of the Academy of Psychosomatic Medicine, Fellow of the American Geriatrics Society, Associate Fellow of the American College of Cardiology, and Assistant Attending, Internal Medicine, Coney Island Hospital, Brooklyn, New York.

LIFE is a continuous process with the result that aging becomes an inevitable process leading to physiologic, chemical, anatomic and psychologic changes. Physically, it manifests itself by a steady and progressive decline in all functions.

By definition, anatomy is the science of the structure of the body. Physiology is the function of the body. All function is physiology. The function of the brain is physiology; and since all mental function relies on cerebral function, the brain is the organ of the mind and all psychology is cerebral physiology. We must cope with progressive senescent changes which manifests themselves at different age levels and in separate organ systems. These changes include gradual impairment of "homeostasis"; cellular atrophy and degeneration of the nervous system; and disturbances in cell growth and tissue reparation. As the general

cortical function diminishes because of fatty and pigmentary degeneration of nerve cells, perception is decreased. To this impairment is usually added deafness and diminished acuity of vision, as well as lack of interest in intellectual matters. As the intellectual interest wanes, the instinctive interests become relatively prominent. Men imagine themselves strong in instincts and women concern themselves mostly with marriage and childbirth. With a decreased perceptual acuity, they spend their hours in reminiscence with the result that they revert to early experiences and try desperately to maintain the standard of their youth.[1]

The following statistics published by the National Conference of Aging in Washington should make us take notice of the clinical portent of our population. There are 12,000,000 persons, or more, past the age of sixty-five in the United States. Since 1900, the United States population has doubled and the number of persons past sixty-five has increased fourfold. By 1960, this group will number almost 15,000,000 and by 1970, almost 20,000,000. Obviously, we are confronted with problems by a large and increasing aged population and the need for gerontologic awareness becomes ever more cogent.

While the aged are subject to paranoid psychoses, depression and states of agitation, they are also subject to typical senile syndromes which are difficult to categorize except possibly to explain them as an aftermath of normal senile changes. Therefore, this presentation will deal with reactions to normal senility. An effort will be made to bring to the fore these behavioral patterns which suggest the insidious onset of senescence, so that we may be better equipped to understand these people and be in the vanguard for promoting social and economic means whereby they would be able to receive adequate emotional gratification and assistance through various resources at our command.

The psychologic disorders of the aged are usually those due to the removal (because of the inevitable senescent changes) of the influences of training, education and experience on primary personality patterns. Second, we see the emotional reactions which are basically a "detached syndrome"—a reaction to the loss of a loved one, friends, job, business or professional pursuits or power and influence, or loss of home or money and so forth. Third, there are the psychoses resulting from senescence and arteriosclerotic degenerative brain lesions and those secondary to somatic disorders. The latter is out of the province of this paper. It must be added, however, that psychotic episodes lasting hours or days may occur during cardiac decompensation, cerebral vascular insufficiency, dehydration and postoperative procedures. To all intents and purposes these are delirious reactions and are usually soon reversible.

The cardinal symptoms of senility are the psychic reactions to the "detached syndrome" and misoneism which is a dislike of and distaste for anything new.

The ease with which a senile person accepts dependency gives rise to psychologic regression—the concept of second childhood. The aged forget where they are, do not know how to operate modern equipment and continuously ask questions which have been answered numerous times. What appears to be a change in personality, is in reality an unmasking of the basic personality. As one ages, one finds it of effort to abide with social conduct and one also cares less. There is a tendency to feel that one has a good record and that one's reputation and character are established. The aged feel that the young should respect them even though they may have done nothing to earn respect except to keep on living. They become short-tempered and irascible. They often shed so much of their esthetic training that they revert to coarseness in conversation and thought.[1] Many are irritable, querulous, lacking in stamina and liable to depression. Impairment in health is aggravated by loneliness and a feeling of being unneeded and unloved.

Nothing appears to bring more pleasure to the aged than the success of achievements and happiness of their children. Quite often these accomplishments are cited as evidence of good stock. Other sources of gratification are respect of their associates in work, business and profession and the memories of past accomplishments. However, modern socio-economic factors tend to hamper such satisfactions. People nowadays marry early in life and have children generally before the age of thirty. Therefore, by the time the parents attain the age of fifty, the children are living on their own and are no longer under the parental influences. The need for the aged in the home, the need for their contribution to the maintenance of the home from a physical aspect is becoming of less significance. The age of mechanization and

automation of home appliances has excised from the older persons the satisfaction of contributing something physical to the home when they live with their children. The independence of today's young married couples seems to thwart any attempt of the aged to share the joys of their children. The counsel and advice of the older people may be construed as meddling. At times they are not trusted to baby-sit for fear of inattentiveness and falling asleep "on the job." Companions and friends die or move away and they find it difficult to mold themselves to these changes.[2] The aged are looked upon as economically inadequate while the young have a prospective and ever-increasing economic value. There is a loss of prestige due to decrease in physical vigor, mental faculties and acumen. Outsiders usurp influence once exercised and resentment follows. Therefore, the separation from children, friends, position, influence and power may result in psychic manifestations which I designate as the "detached syndrome."

The management of psychologic disorders of the aged requires diplomacy, skill and insight into human behavior. It must be a community project in which the family, social service worker and the family physician must contribute to the maintenance and preservation of the mental and physical well-being of the aged. A fair percentage of these people who are not employed are not voluntarily idle. Technologic changes, automation and compulsory retirement contribute to their idleness. Hence, consideration should be given to establishing policies and facilities to enable older people to find work commensurate with their physical and psychologic fitness.

From a psychological aspect, we may start with certain basic assumptions. Unless there is definite evidence of central nervous system disease, it is unlikely that any serious impairment in intellectual or sensory motor function will ensue. This denotes that, in all probability, the psychologic equipment is intact and capable of functioning. Because his physical limitations are not evident to others, he is likely to become more intent and vocal about informing others of their existence. He will become self-centered and more inclined to limit himself beyond necessary requirements of physical safety than would be true with an apparent limitation. If there are certain non-deforming diseases, the aged will ordinarily start with normal psychologic demands and with common reactions to stress and strain. But unless certain measures are taken, his mode of behavior will ultimately involve such infantile retrograde behavior as he is led to believe will assure him of ego-protection. While this does not exhaust the possibilities of the reactions to "old age," it does blanket the more common forms of behavior. The degree and severity of the behavior relies largely upon the amount of motivation the aged possesses towards returning to a place in the everyday world or his desire to excise himself from the situation that he feels may be taxing him beyond endurance.

There are certain psychologic approaches which the physician can make towards preventive mental hygiene which should be initiated promptly. In this way, we can hope to ward off the development of more serious mental reactions which may tend to leave lasting marks upon the behavior. It is important that we provide the aged patient with an opportunity to ventilate his frustrations, fears and concerns. If these vexations are not neutralized, devious routes to comfort his ego may take place. By airing their anxieties, harmful viewpoints are noted, exposed and possibly removed before they become deeply ingrained. The patient should be given emotional re-assurance and intelligent information about his age and its effect upon his life. He should be made to understand that his useful life has not ended, and that to grow old gracefully is an art. The patient should be helped towards a positive viewpoint so that the vast amount of thinking time at his disposal can be channeled into useful, constructive thoughts and deeds, rather than those that contribute to a feeling of inadequacy. He needs to do something, be active and to create. Of course the degree of activity may be curtailed because of infirmities, but even several minutes in useful endeavor several times a day will assist markedly in maintaining morale and serve to assure him of his ability to perform. Not only does this have a beneficial psychologic impact, but it also serves the patient and his physician with information regarding work tolerance and the establishment of a threshold work tolerance.[3]

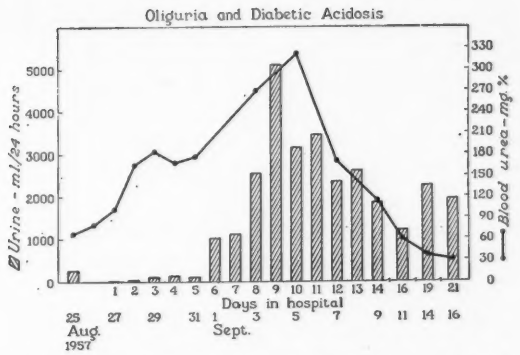
Each individual was an infant. Each infant is an individual with his own rate and potential for physiologic, intellectual and emotional growth and development. Each is influenced by his environment to which he reacts according to his own capacities. Above all, the manner in which a

person meets the impact of senility is a highly specific one involving individual differences. It is the ability of the personality to meet this challenge that, to a large extent, determines future behavior.

Alleviation of fear and anxiety is of paramount importance. There is a level of anxiety which is entirely normal. However, when this level becomes intensified to a point where it interferes with normal thinking, then steps must be taken to control it. In the majority of cases, a little more knowledge and insight into the whims of emotions would add considerably to the comfort of these patients. An effective aid in management is communication. The mind is an ethereal intangible something which can be approached through psychologic means, that is, by influencing the patient through precept and discussion. In the main, when a patient places himself in the care of a sympathetic and understanding physician and transfers to him his personal concerns and co-operates with him, the initial step towards effective management has been taken. The physician must be an interested listener; and by listening and talking to him, the therapeutic effort is greatly advanced. If the therapist is to occupy a position of trust and confidence and gain a modicum of omniscience and omnipotence, he should be a kind and sympathetic person.[4-7]

The importance of assuagement of fear and anxiety is seen in the following experiments done on animals. Experimental animals react favorably to such an avenue of approach. It has been demonstrated that when albino rats were "fondled" for ten minutes daily for three weeks after weaning, they exhibited greater weight gain, more activity and less nervousness as compared to a controlled group. It was found that the animals thrived in proportion to the degree of "petting." As adults, they could be exposed to prolonged excitation with less physiologic changes to the cardiovascular, endocrine and gastrointestinal systems, as shown by immediate necropsy, than could the ungentled controls. Weininger[8] noticed that the adrenal glands of the gentled animals actually weighed less than those of the controls, and hypothesized that the relative immunity to stress damage seen in the fondled or gentled rats may have resulted from lessened pituitary output of ACTH in response to fear stimuli.

Mental hygiene will do much to help the aged. Physicians should be in the vanguard of promoting social and economic means whereby these people would be able to receive adequate emotional gratification through part-time employment, education, rehabilitation and other resources. Many of the aged will be able to return to society except for relatively minor restrictions calling for increased rest, diet and active exercise. Disuse tends to make a person feel inadequate and dependent. Reduction of emotional support is a chief factor in hastening regression and dependence. Community organizations should take the brunt of planning for these older people. There should be a plan for educating people in the problems of the aged. Public communication through lecture halls and other (forms of) media should be utilized to bring education to the aged as well as education about the aged. Thewlis[9] states "to grow old gracefully is an art" and that our attitude towards the aged should be a positive one and not a negative one. Unfortunately, human sympathy is world-wide in scope but not in action.



The approach to the aged must be an holistic one which includes: the lessening of fear and agitation, supplying of emotional re-assurance, the use of psychopharmacotherapy, the striving for an ideal patient-doctor rapport with attempts to give the aged insight as well as physical care—to keep them functioning.[10] Hence, in summary there should be a program of re-education, re-integration and re-orientation.

Diabetic Acidosis Complicated by Acute Renal Failure

Output of urine and content of urea in the blood, August 25 to September 16, in patient with diabetic acidosis complicated by acute renal failure.

● *Under the best of conditions, administration of the correct amounts of electrolytes and fluids in the treatment of diabetic coma poses a most difficult problem. The complexities of management are multiplied when renal failure complicates diabetic acidosis. This case report outlines the treatment in such a combination.*

CLIFFORD F. GASTINEAU, M.D.

Section of Medicine, Mayo Clinic and Mayo Foundation

Rochester, Minnesota

IN MOST instances of diabetic acidosis, there is a degree of azotemia which is rapidly ameliorated by rehydration and correction of the acidosis.[1] This can be attributed to both increased breakdown of protein (gluconeogenesis) and to changes in renal function. Decreases in renal blood flow, the glomerular filtration rate and specific tubular functions during acidosis have been demonstrated by Bernstein and associates.[2] Reubi has shown that hemoconcentration and increased viscosity of the blood will explain the observed renal ischemia.

Circulatory failure has been regarded by Howard[3] and Danowski and associates[4] as a common finding in patients dying of diabetic acidosis. A decrease in total peripheral circulatory resistance, with some increase in cardiac output, was observed by Howarth and associates[5] by means of cardiac-catheterization studies among patients in diabetic acidosis. The occurrence of such circulatory failure has been attributed to depletion of salt,[4] to the low pH of body fluids[6] and to hypokalemia.[7] Even a slight degree of peripheral circulatory failure would be expected to intensify renal ischemia resulting from dehydration and increased viscosity of the blood.

Although azotemia usually is corrected quickly after rehydration, there are some instances in which the value for blood urea or creatinine continues to increase for a number of days before a return to a normal value commences.[8,9] Results of specific tests of tubular function also have been shown to return to normal only slowly in some patients, and on this basis Bernstein and associates[2] suggested that renal ischemia may cause a reversible organic lesion similar to, but milder than, a lower nephron nephrosis. The absence of initial oliguria perhaps could be ascribed to the diuretic effect of the glycosuria occurring during acidosis and the mildness of the process.

In a smaller number of instances, however, actual oliguria or anuria lasting several days may occur.[9-11] The cases reported are few, but in these cases the process has run a course very similar to that seen in acute renal failure after traumatic shock. Brody[12] reported two instances of oliguria in diabetic acidosis in which the renal changes found on postmortem examination were consistent with the presence of the "lower nephron syndrome."

Thus, three degrees of renal change occurring

in or following diabetic keto-acidosis can be postulated.

First is a decrease in renal function quickly reversible by treatment of the acidosis. Oliguria of a few hours' duration, with prompt recovery of renal function, has been described[13] and would fall in this category.

Second is mild organic tubular damage resulting in azotemia for a number of days but without initial oliguria.

Third is more severe tubular injury resulting in anuria or oliguria of varying degree and duration.

A direct toxic action of the ketonemia might be considered as a cause of the renal injury in diabetic acidosis, but we have no proof of this mechanism. Hypokalemic nephropathy ordinarily does not exhibit the oliguria and retention of nitrogen characteristic of this syndrome.

The case reported herein illustrates an example of oliguria or anuria developing during diabetic acidosis.

Report of Case

A thirty-one-year-old woman was admitted to the hospital at 3 p.m. on August 27, 1957, because of oliguria of approximately 41 hours' duration. She had been completely well until a month previously, at which time symptoms of weakness and loss of weight appeared. Polyuria, polydipsia and vulval irritation had been noted two weeks prior to the patient's admission, and nausea, vomiting, dyspnea and weakness became increasingly severe during the 5 days before admission. Repeated questioning revealed no known exposure to any toxic agents.

The patient had become comatose on August 25, and at the time she was first seen by her referring physician* she was incontinent and apparently was passing urine freely. At 12:00 noon on that day (August 25) the value for blood glucose was 580 mg. per 100 cc., the carbon dioxide-combining power was 9.6 mEq. per liter of plasma, and the urine exhibited grade 4 albuminuria, glycosuria, acetonuria and casts. The patient received 100 units of crystalline insulin, and during the next 6 hours 2000 ml. of 1/6 molar sodium lactate and 20 mEq. of potassium chloride were administered intravenously. During the seventh hour of treatment she became cyanotic, and respirations were shallow. An electrocardiogram showed a bigeminal rhythm with premature ventricular systoles and depression of the S-T segments. She was quickly given 6 mEq. of potassium chloride intravenously, followed by 14 mEq., administered more slowly. Improvement resulted within ten minutes with a reversion to sinus rhythm and deeper respirations. She excreted only 250 ml. of urine in the first ten hours, and thereafter excreted only a few milliliters until August 28, when she excreted 30 ml.

The use of solutions of glucose and potassium chloride was continued, and she received 25 units of insulin every six hours. The value for potassium on the morning of August 26 was 2 mEq. per liter of serum, and the carbon dioxide-combining power was 17.2 mEq. per liter. She began to recover consciousness during the evening of August 26, about thirty-two hours after the start of treatment.

The patient was transferred to a Rochester hospital on August 27 because of continued oliguria. During the preceding fifty-one hours of treatment she had received a total of 7 liters of water, 120 mEq. of potassium, 450 mEq. of sodium, 270 mEq. of chloride, 300 mEq. of lactate ion and 275 units of insulin.

We found the patient to be stuporous. She responded inconsistently to questions. The respirations were somewhat increased in rate and depth, and the hepatic margin was palpable and tender. There were no râles or peripheral edema. The carbon dioxide-combining power was 10.3 mEq. per liter of plasma, the value for blood glucose was 323 mg. per 100 cc., that for potassium was 2.6 mEq. per liter of plasma and that for blood urea was 102 mg. per 100 cc. Only a trace of acetone could be found in the plasma by acetone test powder, and no salicylate ion could be demonstrated.

She was given 100 units of crystalline insulin subcutaneously, and within three hours the blood sugar had decreased to 168 mg. per 100 cc., and no acetone could be found in the plasma. It was concluded that the diabetic acidosis was largely corrected. Subsequently she was given 10 to 37 units of insulin daily.

A total of 2150 ml. of fluids was given intravenously during the first twenty-four hours after admission of this patient. This contained 305 mEq. of sodium, 265 mEq. of chloride and 40 mEq. of lactate ions.

Improvement in strength and alertness was gradual. Tube feedings of a 20 per cent solution of glucose and a prepared nutrient (lipomul) were given on the second and third days of hospitalization, and a rice and fruit diet was permitted on the fourth, fifth and sixth days. During the period of oliguria the oral intake was kept between 370 and 400 ml., except on August 29, when 1370 ml. was given. A graduated diabetic diet was begun the seventh day, but was taken poorly the first few days. The changes in the blood urea are shown in the illustration. There was a gradual increase until a maximum of 323 mg. per 100 cc. of blood was reached on the tenth hospital day. Satisfactory urinary output began on the sixth hospital day and increased to a peak of 5100 ml. on the ninth day. The urine was found to contain albumin and casts. The liver was no longer palpable, and it was felt that the enlargement may have been evidence of mild congestion, since some degree of pulmonary congestion was seen in the roentgenogram of the thorax the day after admission. There is also the possibility that the hepatomegaly was the result of fatty infiltration. The prothrombin time and result of the thymol turbidity test were within normal limits on admission.

*Clinical observations made prior to admission of this patient to the hospital were kindly supplied by Dr. Lawrence O. Goodman, of Marshalltown, Iowa.

No hypotension was noted at any time.

The carbon dioxide-combining power remained between 10.3 and 12 mEq. per liter of plasma from the time of admission to the tenth hospital day, and only by the sixteenth day had it increased to 20.9 mEq. per liter. The plasma was not found to contain acetone on a number of occasions during this time, and the persistently low carbon dioxide-combining power was considered to be the result of accumulation of nonketonic acidic metabolic products, as well as being a reflection of hyponatremia. The value for sodium was between 123 and 128 mEq. per liter of serum during the first several days, but decreased to 116 mEq. per liter on the tenth hospital day after diuresis had begun.

Values for blood sugar were variable, ranging between 173 and 390 mg. per 100 cc. There was only occasional glycosuria however (when urine was available for analysis). No observations were made which would permit an accurate estimation of threshold, but the impression was gained that the threshold was considerably elevated.

The value for potassium was 2.6 mEq. per liter of serum on the first hospital day, and 60 mEq. of potassium phosphate was given intravenously during the first night. The value had increased to 3 mEq. per liter of serum by the next morning. No more potassium was administered because of the possibility of hyperkalemia with continued oliguria. There was a gradual increase to 4.6 mEq. per liter on the sixteenth hospital day.

The clearance of blood urea was 42.4 ml. per minute at a urinary volume of 4.1 ml. per minute and a urea content of 30 mg. per 100 cc. of blood on the twenty-first hospital day. The patient was dismissed on September 20, after twenty-five days in the hospital, and 18 units of NPH insulin was prescribed to be taken daily.

This patient returned for re-examination on January 21, 1958. The diabetes had been difficult to control, and she was experiencing occasional reactions of hypoglycemia. She was feeling well generally. The clearance of urea was now 86.7 ml. per minute at a urine volume of 9.88 ml. per minute and a urea content of 36 mg. per 100 cc. of blood. Urinalysis revealed no albuminuria and no formed elements.

Comment

The renal failure which follows traumatic shock generally is regarded as the consequence of renal ischemia and the resulting injury to the tubular epithelium. The similarity between the clinical course exhibited by this patient and the usual post-traumatic "renal shutdown" may be taken as circumstantial evidence of a common mechanism. The direct demonstration by Reubi of decreased renal blood flow resulting from dehydration and increased viscosity of the blood is additional evidence for this view.

In this case oliguria was present from the time the patient came under medical observation, only 250 ml. of urine being formed within the first 10 hours. It is likely that the extensive dehydration and hemoconcentration after several weeks of polyuria are adequate to explain the initial oliguria. The episode of cardiac arrhythmia occurring at the seventh hour of treatment could well have caused additional renal ischemia and tubular injury.

In most instances of diabetic acidosis the kidney retains some ability to dispose of excessive loads of water or electrolytes. Thus, treatment can be undertaken with confidence that, if circulatory failure does not develop, the administration of modest excesses of water or salts will not harm the patient. If oliguria or anuria develops, however, the attending physician is deprived of this degree of freedom in the choice of fluids to be given parenterally. He must estimate water and electrolyte requirements as precisely as possible and avoid the equally hazardous pitfalls of inadequate and excessive therapy. The extensive distortions of cell composition and of extracellular fluid structure that have occurred during the period of development of the acidosis make it particularly difficult to know when enough of the various electrolytes and water has been given. Certainly, it is not enough to aim for normal composition of the plasma alone. Too often there is the ironic comment, "The carbon dioxide-combining power was back to normal, but the patient died."

Once the physician feels that water and electrolyte deficits have been corrected in the oliguric patient, there is the problem of administering sufficient amounts of carbohydrate without excessive water; he must prevent hypoglycemia and meet the metabolic needs of an unstable diabetic patient without increasing total body water. The amount of water that can be administered safely to an anuric patient has been estimated to be about 400 ml. per day.[14] Reasonably good diabetic control during the period of oliguria is all-important, since poor control would permit an accelerated catabolism of body protein and would result in a more rapid increase in the degree of azotemia.

Summary

Oliguria of six days' duration occurring in the course of diabetic acidosis is described. The patient recovered, and there was no evidence of renal dysfunction three months later. Renal ischemia and the resulting tubular injury are regarded as the most likely causes of such oliguria.

MM

Levator Spasm Syndrome

Presented at the meeting of the Minneapolis Academy of Medicine, Minneapolis Club, February 17, 1958.

IT IS the purpose of this discussion to bring to your attention a relatively common ailment seen in proctologic practice and in practice, in general. It has been adequately described by George H. Thiele in a series of papers in the last twenty or so years. Generally speaking, it is described as a painful spasm of the levator ani, coccygeus and the piriformis muscles, either separately or as a group. The syndrome, in my experience, is distinguished in part from true coccydynia because actual pain or soreness in the coccyx is lacking entirely in about one-half or more of the cases. Those cases in which actual coccygeal symptoms are absent or difficult to elicit have vague, indefinite, yet annoying or disabling "rectal" discomfort.

The cases to be emphasized and discussed are distinguished from those in which the primary symptoms are localized in the tailbone. Sir J. Y. Simpson, in 1859, called attention to the fact that when the coccyx was injured or when any of the group of surrounding tissues were the seat of inflammation, any contraction of the muscles attached to the coccyx resulted in the characteristic pain of coccydynia. He made no mention, however, of muscle spasm nor did he discuss any etiologic factors other than trauma.

Thiele emphasized spasm of certain muscles inserted into the lateral border of the coccyx as being responsible for the pain. These muscles include the levator ani, coccygeus and bundles of fibers from the gluteus maximus. He also noted that about one-third of these people also complained of pain in the superior gluteal region and down the back of the thigh and that, without exception, these patients had tenderness and spasm of the piriformis muscle.

Inflammation is considered by most investigators as the chief etiologic factor in this syndrome. This involves, particularly, infection in adjacent pelvic viscera causing reflex spasm of the pelvic floor muscles. Thiele referred to this as focal infection and includes such entities as anal fissure, hemorrhoids, proctitis, prostatitis, urethritis, cervicitis, salpingitis, et cetera.

Traumatic factors are occasionally responsible.

TABLE I. CLASSIFICATION (AS TO ETIOLOGY)

I. Inflammation:		
	(a) Male:	Urethritis
		Seminal vesiculitis
		Prostatitis
		Cystitis
		Anal fissures, hemorrhoids, proctitis, et cetera
	(b) Female:	Cervicitis
		Salpingitis
		Cystitis
		Vaginitis
		Anal fissures, hemorrhoids, proctitis, et cetera
II. Trauma:		
		Childbirth
		Fall, kick, or other direct trauma
III. Psychogenic:		
		Hysteria
		Neurosis

WILLIAM T. SMITH, M.D.
Minneapolis, Minnesota

Dr. Smith is Clinical Instructor in Surgery, University of Minnesota Medical School.

These include falls, pregnancy, parturition, bumps against furniture, prolonged automobile rides and a few other miscellaneous injuries. In my own personal experience and on a number of occasions, I have been unable to establish a positive etiologic factor for the pain and spasm. It seems in these cases that the general loss of tonicity of the pelvic muscles, particularly in women, and poor sitting posture is the fault. Many of these people are confirmed slumpers who sit in such a way that the pressure is exerted over the upper buttocks, coccyx and base of the sacrum. It also seems that this poor posture may produce undue fatigue and spasm of the supporting pelvic muscles.

Many, including Thorek, consider this syndrome to be of psychoneurotic origin. Those in particular who consider the patient's symptoms vague and indefinite and who cannot find definite etiologic factors are likely to label him "neurotic." This, in my opinion, is an admission of defeat. Occasionally patients suffering from this entity have a cancer phobia. This can be dispelled by a careful examination, a clear description of the difficulty, re-assurance and treatment.

The syndrome is most prevalent in adult women and is most common in the fourth decade of life. In my own series, about 80 per cent were women and this percentage corresponds with Thiele's, Foster's and Duncan's experience.

TABLE II. AGE INCIDENCE

Age	Patients
23 to 30	4
30 to 40	34
40 to 50	58
50 to 60	46
60 to 70	7
74	1

Most of us are familiar with the symptoms of a painful coccyx, particularly those symptoms associated with fresh or recent trauma. Invariably these patients complain of a sore tailbone and find it difficult to sit unless the weight of the body is shifted away from this bony appendage. History of recent trauma makes the diagnosis obvious.

In my experience, the most common symptoms associated with levator spasm (Thiele's syndrome)

are often vague and sometimes it is difficult for the patient to describe or localize them. It is commonly referred to as an aching or discomfort in the rectum or pelvis. On close questioning, the patient describes it as an aching or throbbing, at times reaching an agonizing intensity. Sometimes an acute, severe attack may be experienced at night, awakening the patient and lasting several minutes to an hour. This group of symptoms has been described under the term "proctalgia fugax."

In contrast to the pain associated with anorectal disease, this aching is not particularly accentuated by bowel movement and in most cases, suggestions of existing anorectal disease such as protrusion, bleeding, and so forth, are entirely lacking. The symptoms may be present for a few weeks to a year and sometimes may follow anorectal surgery. Most of these people do not tolerate long automobile rides, prolonged sitting in slumped positions or occasionally long standing in one position.

Diagnosis

Because of the peculiar complaints and lack of associated symptoms, the difficulty is often overlooked or not considered at all. That old moss-grown adage "one finds what one looks for" certainly applies here. Only too often, many of these people have carried their complaints to numerous gynecologists, urologists, orthopedists, chiropractors without any organic difficulty having been recognized. I have been amazed on numerous occasions at the complicated examinations to which these patients have been subjected without any conclusive or positive findings having been recorded or any treatment suggested. Still others have been commonly diagnosed and treated for such maladies as prostatitis, pelvic inflammatory disease, sciatica, and slipped disc.

It is commonly observed that most of these people sit in a slumped position, resting the weight of the body on one buttock or the other. Most of them complain of accentuation of pain when rising from a sitting position or when they attempt to sit squarely on a chair. The most common physical finding on digital examination is tenderness and spasm of one or more of the pelvic floor muscles, the offenders usually being the levators, coccygeus or the periformus. The affected muscle or muscles will often feel contracted and spastic. This gives the sensation that the muscle is actually larger than normal. If only unilateral involvement is present, the uninvolved side feels flat and relaxed. In cases of true levator spasm syndrome, the coccyx is not painful on bi-digital examination. Application of pressure to the involved muscle will reproduce or intensify the pain which caused the patient to seek relief. In the majority of cases, the involvement is unilateral and for some unexplained reason often left and anteriorly. It should be emphasized, however, that this difficulty is not necessarily limited to one side or one group of muscles on one side of the pelvis. In Foster's cases, the coccygeus was most often involved. In Thiele's and my cases, the levators were most commonly involved.

Examination may be done in the inverted or left Sims's position. The gloved finger is inserted the full length of the rectum, the flexor surface being just anterior to the coccyx and sacrum. Bi-digital examination of the coccyx may produce some tenderness. As the finger is moved laterally, anteriorly and medially it passes over the piriformis, coccygeus and levator muscles. Only part of the periformus can be felt with the tip of the finger while most of the coccygeus and the levators can be felt as they proceed to their insertion to the coccyx and sacrum. The spastic tender muscles have the characteristics described. If this disease goes untreated for years, the affected muscle due to continued spasm may become small and feel like ligamentous or fascial bands.

X-ray is of little or no value in the diagnosis. Occasionally severe unilateral spasm of the levator ani and the coccygeus may pull the coccyx to the affected side. This, however, can be demonstrated by physical examination and x-ray contributes little, if anything, as an additional diagnostic measure.

The hip and leg pain which often accompanies this syndrome is usually due to spasm of the piriformis muscle. Spasm of this muscle will often produce pressure on the sciatic nerve as it merges through the sacro-sciatic foramen and on the superior gluteal nerve as it passes between the upper border of the spastic piriformis and lower border of the gluteus maximus. Spasm of the piriformis is concommitant with spasm of the levators and the coccygeus in approximately 25 per cent of the cases.

The diagnosis of this syndrome rests upon the demonstration of a spastic tender muscle or muscles of the pelvic sling. Inflammatory disease of the anorectum and adjacent viscera should be sought but in most instances it cannot be demonstrated.

Treatment

The treatment of this spastic muscle syndrome consists of massage of the involved muscles and/or surgical or medical control of the inflammatory processes if any are present. Massage is best accomplished with the patient in the left Sims's position. The index finger is inserted the full length of the anus with the flexor surface anterior to the coccyx. With gentle but firm pressure the finger is drawn over the bellies of the spastic muscles in a posterior-anterior stropping motion. If the muscles are acutely tender, having the patient bear down may help to relax the tender muscle and the massage is better tolerated. Massage is continued on each side for fifteen or twenty strokes, which takes about five minutes. This is repeated daily for four or five days and then every other day until improvement is shown. It is wise to advise the patient that after the first or second treatment the pain may be accentuated temporarily. After half a dozen treatments, most patients show a definite improvement. Massage is then continued at regular intervals until the pain has disappeared and no further treatment is necessary.

At home, the patient is advised to take sitz baths, warm water enemas and aspirin as an analgesic. Drugs designed to reduce muscle spasm have been of no value in several of my cases. Voluntary contraction and relaxation of the gluteus maximus and the pelvic sling muscles is valuable exercise to improve the tone of these muscles and reduce spasm. This can be done hundreds of times per day without any inconvenience and it seems to be particularly valuable in women with loose, sagging pelvic muscles. Instructions as to proper sitting posture are highly important. These people must be warned not to sit in a slumping position. The best posture is sitting on a firm surface with very little give and allowing the weight to rest upon the ischial tuberosities and muscles of the back of the thigh. Slumping with the lower back convex and the body weight exerted upon the sacrum and coccyx definitely aggravates and perpetuates the trouble. Diathermy has been of some help but only when used with frequent massage. Coccygectomy is to be avoided except in rare cases of fracture, osteomyelitis, et cetera. Thiele reported five cases in which coccygectomy had been done without relief of symptoms. Upon massage, four patients of this group were definitely improved and one remained the same.

Correction of local anorectal disease is sometimes of value in those cases which do not respond to massage. Likewise, diseases of the neighboring viscera should be treated as part of the program. This includes pelvic inflammatory disease, cystitis and cervicitis. Only 40 per cent of the cases seen have been found with associated diseases in the neighboring organs which leaves 60 per cent with no demonstrable etiologic factors. In those cases in which no definite etiologic factors were present, recurrence of symptoms not infrequently occurred, not unlike tender and spastic muscular conditions in other parts of the body. Massage in these cases relieved the symptoms but it was no guarantee that spasm and pain would not recur. The patient should be warned of the possibility of recurrence and advised that additional treatment may be necessary from time to time.

Summary

Levator spasm syndrome is a common difficulty frequently overlooked or mistaken for something else and often going untreated for years. Nearly all of these patients complain of pain in the general region of the rectum. The diagnosis is easy. The treatment is simple and readily administered and the results are most gratifying.

Discussion

R. J. Tenner, M.D.: I would like to thank Doctor Smith for this fine presentation of a very hard-to-explain condition in the rectum. This can best be described as a "charley-horse" or a cramp in the muscles that surround the rectum, namely, the levator ani and coccygeus muscle. The patient might describe it as similar to a cramp in the muscles of the calf which, of course, one can readily rub out and relax. This is also the accepted treatment by the physician for the spasm of the rectal muscle, namely digital massage.

Mancell T. Mitchell, M.D.: Parturition naturally places considerable strain and stretch upon the levator ani muscles, the sacro-coccygeal joint and the sacro-coccygeal ligaments. There may be considerable bruising and stretching of the soft tissues surrounding and overlying these structures. Occasional hematomas are seen. Operative deliveries and precipitate deliveries increase the likelihood of this.

Rest, as traditionally emphasized by the "lying-in" period, has been the principal therapeutic agent in treating this. Hot baths, hot douches and occasionally diathermy have been used as adjuvants.

In the cases that are slow to respond, massage as indicated by Doctor Smith, may play a decidedly helpful role in helping to relieve the pain and discomfort.

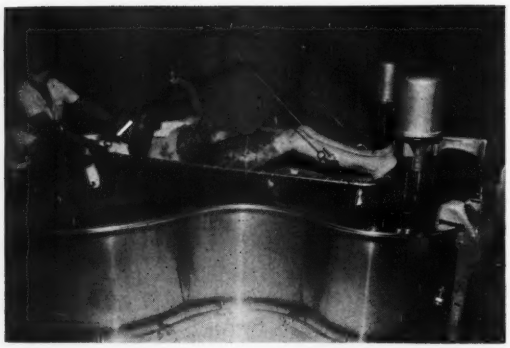

Fig. 1. Patient is being lifted from the tank after all dressings have been removed. This demonstrates the comfort and ease of handling a heavy patient by means of the power-operated overhead hoist.

● *Few things are as time-consuming for the physician and as painful for the patient as the changing of dressings in severe burns. Submersion of the burned patient in agitated water in a Hubbard tank can provide great aid in the management of such patients. This treatment does not interfere with but rather is of assistance in skin grafting.*

Use of the Hubbard Tank as an Adjunct in the Management of Severe Burns

THE TREATMENT of burns can be divided into three very important phases: (1) immediate and supportive care, (2) preparation of the recipient sites for grafting and (3) actual placement of the grafts and their aftercare.

Like so many other aspects of medicine the success of the care that follows rests heavily on the thoroughness and effectiveness of the earlier phases. Any change from tried methods must be accompanied by mature consideration and naturally by uneasiness. On the other hand, if a change in method can be easily incorporated into the over-all scheme of therapy with a saving in discomfort and hospitalization without jeopardy to the patient, then the change is a good one.

Methods of Débridement of Extensive Third-Degree Burns in Preparation for Grafting

Severe burns, particularly those involving areas that are difficult to dress, such as the thorax, abdomen, upper part of the thighs and buttocks,

often represent real nursing problems after the initial acute phase is passed. In the large or obese patient the problems are magnified. It is particularly in these patients that use of the Hubbard tank is a definite aid in the care of extensive second and third-degree burns.

Several methods are described for the removal of eschars in preparation for grafting.

1. Moist dressings that are changed at regular intervals are used by many,[1] but this method is time-consuming, actually requiring many days to

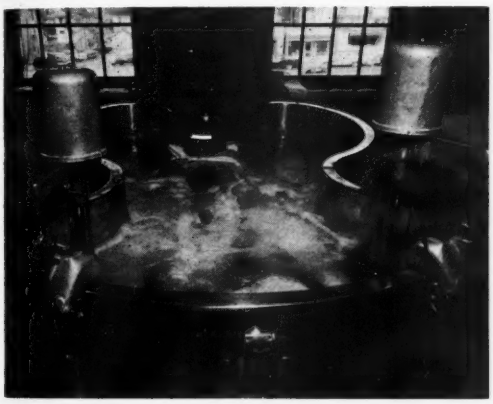

Fig. 2. Patient is immersed in the tank. Note the turbulence created by the two electric turbines at the foot end of the tank. Note also the ease with which a large person is accommodated in this tank.

float off eschars even with the use of half-strength Dakin's solution or weak acetic acid solution.

2. Enzymatic débridement is theoretically ideal but it presents real problems. Penetration of the eschar is practically impossible without cross hatching and by so doing one may damage granulations underneath. Furthermore, its use is moderately painful and is expensive.

3. Surgical excision with the patient under anesthesia has been described by Mason[2] as the most logical and generally accepted procedure for early removal of slough. It is accompanied, of course, by the small but definite risk of anesthesia, the spiking fever and chills that often follow in the first 24 hours after surgical débridement, and the inevitable loss of blood from manipulation of delicate granulations under the eschars when the latter are excised. Artz and MacMillan[1] have expressed the view that excision of the eschar is rarely indicated.

4. We feel that immersion of the patient in water and gentle cleansing by the method to be described offer a most satisfactory means of preparing an extensive burn for grafting. Also that by this method, second-degree burns very frequently may be more rapidly and effectively "cleaned up" and re-epithelization hastened.

Use of Hubbard Tank.—The tank that we now use is actually the Currence modification of the Hubbard tank.* It is a commercially built tank which is about 8 feet long, has the shape of a figure 8, allows depth of water to about 18 inches and has two electrically operated turbines† which pump aerated streams of water in any desired direction. It is of stainless steel, is easily cleaned and can be made essentially sterile before the patient is placed in it. The agitators in the tank

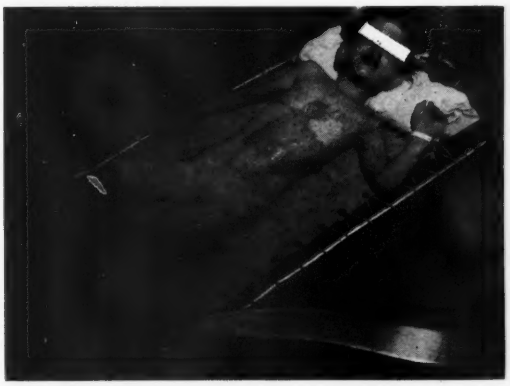

Fig. 3. An eight-year-old child at the time of her second tubbing. All dressings have been removed in the tank without traumatizing the burn wound in any way. Loosened eschar can now be removed in the tank with sterile instruments.

are of benefit in loosening the adherent dressings and eschar; warm water gently agitated to form currents or streams cleanses the patient more thoroughly and effectively than does unagitated water. The water used is from the city supply and enters the tank at whatever temperature is desired through a thermostatically controlled mechanism.

*Hubbard tank, 300 gallon capacity, made by Ile Electric Corp., Long Island City, New York.

†Agitator made by Ile Electric Corp., Long Island City, New York.

Some persons advocate saline baths, which are physiologically more sound but which practically are of little advantage. The additional expense of saline baths makes them not practical in most instances.

On about the seventh to the tenth day after the burn, the patient is taken to the department of physical medicine on a Stryker frame, lifted from the stretcher by an industrial electric hoist on an overhead track** and, except for the head and neck, is submerged in the water at a temperature of 100° F. The outer dressings are loosened or cut away. After fifteen minutes of soaking, the remaining dressings can be removed completely with ease and without pain. The edges of the eschars that are free are then lifted and excised.

Following this, 1 tablespoon of detergent (Dreft) is added to the water and the water is gently agitated by electrically driven turbines for another ten to fifteen minutes. The water with detergent more effectively loosens the accumulated secretions and epithelial debris than does the agitated water alone (Figs. 1, 2 and 3).

Then the patient is quickly removed from the tank, covered with a sterile sheet and transferred to a stretcher. The sheet is removed and nitrofurazone (furacin)-impregnated, fine-mesh gauze is layered smoothly over the areas of second and third-degree burn. Usually two physicians, masked and gloved, can apply the dressings rapidly enough to avoid chilling of the patient from exposure to the air.

In general, the decision for open or closed methods of care is based on several factors. Most burns of the arm and forearm are circumferential and also involve the hand. More comfort and easier immobilization in position of function are possible with contour compression dressings of the arm and hand. If the patient is ambulatory, contour dressings may be used on burns over the trunk and thighs. However, many times the extent of burns precludes ambulation, and the open method of management may seem wisest. In these cases, frequently a single layer of nitrofurazone gauze is all that is applied over the granulating areas, as this seems to prevent the drying and cracking of the surface of the granulations. A cradle is used to keep sterile sheets away from the areas covered by nitrofurazone dressings.

The eschars are removed easily, rapidly and relatively painlessly by "tubbings" every day or every other day. No loss of take of skin graft could be attributed to this type of preoperative treatment even when performed on the morning of grafting. In fact, as a usual procedure patients are taken from the tank, covered by a sterile sheet and brought to the operating room where the skin grafting is done. Some authors have expressed the belief that the granulations should not be cleaned too thoroughly because of the fear of removing the fibrin and "natural glue" so important to the take of a skin graft. We do not believe that there is a sound basis for this fear; rather, we think that gentle mechanical cleansing of the granulating areas is an important step in the preparation of the part to be grafted.

Frequently in the management of burns, after the general condition has stabilized and the patient seems to be progressing satisfactorily, the local care of the burn can become most arduous to both the patient and the physician. This seems to be especially true in children and in very obese adults as well as in very apprehensive patients. Since this stage in the handling of burns is most important, it follows that anything which makes life easier for both the patient and the physician, and speeds the time from burn to grafting, is to be desired. Use of the Hubbard tank in the manner described is most satisfactory in all these respects.

Illustrative Case

A thirty-seven-year-old housewife whose weight exceeded 200 pounds suffered a deep second and deep third-degree burn over 35 per cent of her body surface from an oil flame on March 14, 1958. The burn involved the right arm, forearm and hand, abdomen, flank and right thigh. After seven days' care at a local hospital she was transferred to the Mayo Clinic.

Her initial treatment here was supportive; electrolytes and blood were administered, and a liberal ulcer diet with protein supplements was used at first. Also, she was given additional tetanus antitoxin and tetanus toxoid and was started on chemotherapy.

A program of hydrotherapy was begun on March 25. The patient was submerged, except for the head and neck, for a total of twelve times at intervals of approximately every other day. On April 9, after the usual thirty-minute tubbing, she was taken to the operating room where split grafts were applied to the arm, forearm and hand, and postage stamp-sized split grafts were applied to the anterior and lateral aspects of the right thigh. Again, on April 15 and April 18, the tubbings were carried out without apparent deleterious effects on the grafts.

**Chisholm Moore Hoist Corp., Tonawanda, New York.

A review of the temperature chart showed no consistent change that could be attributed to the tubbings. In fact, the mean curve of the temperature was lower after March 29, but this could have been due to the alteration in chemotherapy.

This case was handled as indicated because the patient's weight and apprehension would probably have made dressing and local care of the burn most difficult by any other means of management.

Advantages of Method

This method of treatment has several advantages:

1. It is comfortable to the patient. Anesthesia is not needed for change of the type of dressing used and for débridement. Everyone who has experienced the anguish involved in change of dressings by other methods without anesthesia would be most impressed to see the relative ease with which all dressings can be removed, even in children, with only minimal sedation, usually with morphine sulfate, in the more apprehensive individuals.

2. It speeds care. Not only can depth of burn be ascertained as early as possible but the method shortens the time until grafting.

3. It reduces surface infection. Although some authors say that surface infection is not an important factor[3] it seems only reasonable that purulence causes the destruction of some of the precariously situated islands of epithelium. Patients treated as described herein are free of odor, do not show gross purulence at tubbings, and do not have spiking fever afterward.

4. It saves skin. Many questionably viable areas of epithelium are saved because the surrounding and covering eschar and infection are removed.

5. It helps in preparing granulations. As mentioned before, preoperative tubbings seem to have no deleterious effect on the take of split-thickness skin grafts even when done on the morning of operation.

6. It helps after grafting. Even after grafting, tubbing for ten to fifteen minutes five to seven days after split grafting helps float away eschar and areas of graft threatened by pockets of infection and serum. No loss of graft attributable to early tubbing has been noticed.

7. It saves blood. Because the patient seldom bleeds from sites where these eschars are gently teased and trimmed off, the total requirements for blood are much less.

8. It saves money. The cost of tubbing and new dressings each day is outweighed by the marked reduction in burn-to-grafting time.

9. It allows early active physical therapy of hands and arms as described by Wise and associates.[4]

Important Points of Management

For ease in management we believe, as does Jackson,[5] that the use of a Foley retention catheter facilitates care through at least the first two phases.

Nitrofurazone gauze placed lightly over granulations between tubbings keeps the surface from cracking and yet avoids maceration. We agree with Blocker and associates[3] that nitrofurazone gives good local antibacterial effect.

Septicemia, however, is an ever present threat to these patients, as pointed out by Artz and Soroff.[6] In their series of 800 burns the cause of death in 30 of the 53 deaths was septicemia proved by repeated blood cultures or by necropsy findings. For this reason, systemic chemotherapy generally is used.

We agree with Blocker[7] and Artz and Soroff[6] that ACTH and cortisone have no place in these phases of burn therapy.

The use of the industrial hoist on an overhead track greatly facilitates the procedure described.

The Detection of Strabismus in a Pre-school Examination

JOHN A. McNEILL, M.D.
Saint Paul, Minnesota

The diagnosis of strabismus in pre-school children is quite simple and very important. The details of observation, the light reflex test, the cover-uncover test and the alternate cover test are presented.

STRABISMUS, or squint, may be defined as a lack of parallelism of the visual axes or the line of sight of the two separate eyes. The most common form of strabismus is esotropia; less common, are outward deviations or exotropia and vertical disparities or hypertropia.

Strabismus always involves both eyes even though one eye is constantly deviated. If that deviating eye be made to fix, the other eye will then deviate so that it is not too important to determine whether a squint is a right tropia or a left tropia or alternating. Ophthalmologists usually attempt to convert a right or left esotropia into alternating esotropia as part of the treatment of the strabismus.

In the detection of strabismus, as in all physical examinations, simple observation is the most important element in diagnosis. If to observation are added two simple tests, all instances of strabismus in children will be found. Since there exist certain physical peculiarities which tend to imitate or mask strabismus, it is important that these tests be added to the physical examination of children.

Fig. 2. Congenital epicanthus. Eyes appear esotropic, but are not. Light reflex is centered in each pupil.

Dr. McNeill is Clinical Instructor in Ophthalmology, University of Minnesota.

Part of a symposium on "Visual Examinations in Pre-School Children," presented at the Minnesota State Medical Association meeting, June, 1958.

The Hirschberg (Light Reflex) Test

The diagnosis of strabismus is greatly facilitated if one holds a light so that the reflection on the cornea of the child may be observed. If the child's eyes are parallel, the light reflex will be centered in the pupil of each eye (Fig. 1a). The reflection of a window or ceiling light serves equally well. This reflection will be in the same area of each cornea. If the eyes are not parallel, the light reflex will be in a different spot in each eye (Fig. 1b). One of the situations which gives the impression of strabismus is congenital epicanthus, an example of which is shown in Figure 2. At first glance, this child appears to have an esotropia, but it is apparent that the light reflex is centered in the pupil of each eye. The appearance of esotropia is due to the congenital epicanthal fold of skin at the side of the nose which covers part of the sclera in this area, particularly when the child glances to one side.

Cover-Uncover Test

To perform this test, first one eye and then the other eye is covered and uncovered while the child is fixing on a light or the observer's finger or anything which will hold the child's attention. If the eyes are aligned, they will hold this straight position. If the eyes are not straight, the deviating eye will jump to pick up fixation when the fixing eye is covered and this determines that the patient has a strabismus. This simple, rapid test can be done on very young children and is reliable providing only that the child is fixing on some object.

The Alternate Cover Test

In this test, the cover is passed from one eye to the other, alternately, allowing time for each eye to fix, but not allowing time for the two eyes to fix together with the cover removed. With this test, even normal eyes would jump a small amount to take up fixation, since a certain amount of phoria or tendency to deviate is normal. This is also a valuable test in a general physical examination, however, because moderate or large amounts of esophoria or even exophoria may require ophthalmologic attention and should be referred for consultation.

A refinement of these techniques is to combine the light reflex test and the cover test by having the child fix on a light and carry out the cover test. These tests can be done at the same time and take only an instant to perform if the child's interest is being held. Inclusion of these tests in all routine physical examinations of pre-school children will save many individuals from the cosmetic and functional blemish of strabismus and salvage the many eyes doomed to the partial blindness of amblyopia ex anopsia.

Metabolic Bone Diseases

The purpose of this paper is to present certain aspects of the calcium and phosphorus metabolism and metabolic bone diseases.

CALCIUM in human serum exists in two forms—the one which is ultrafiltrable and the other, which is non-ultrafiltrable. The ultrafiltrable calcium consists of ionic calcium and the calcium which is reversibly combined with the citrate.[1] Since the latter is negligible in quantity, the ionic calcium accounts for most of the ultrafiltrable calcium. The non-ultrafiltrable calcium consists of mainly the calcium which is reversibly combined with the proteins. Evidence in the literature indicates that calcium is also present in reversible combination with cephalin as non-ultrafiltrable calcium.[2]

The mean total and ultrafiltrable calcium, in the normals, as reported previously[3] are 9.84 ($\pm$0.46) and 5.24 ($\pm$0.214) mg. per cent, respectively. The mean percentage of ultrafiltrable calcium was 53.3 per cent ($\pm$2.48) when the pH of the serum ranged between 7.3 to 7.7 during the process of ultrafiltration.[3] These values for ultrafiltrable calcium are in agreement with those reported by McLean and Hastings[1] using frog heart technique and that of Yendt, Connor, and Howard[4] using *in vitro* calcification of cartilage of rachitic rats. Hopkins, Howard, and Eisenberg,[5,6] reported that the ultrafiltrable calcium in the normals was 65 to 75 per cent of the total if the pH of the serum was controlled by bubbling 5 per cent CO_2 in O_2 prior to ultrafiltration. Our results indicate that by bubbling 5 per cent CO_2 in the separated serum, an initial lowering of pH and increase in CO_2 content resulted, and the range of ultrafiltrable calcium in healthy human subjects was found to be 57 to 76 per cent.[3]

More recently, Toribara, Terepka and Dewey[7] reported that in normals the ultrafiltrable calcium is 60 to 70 per cent of the total, as determined by their method. A lowering of initial serum pH results if it is controlled by the method described by Toribara, Terepka and Dewey and this accounts for their higher values for ultrafiltrable calcium.[8] Our results show that by equilibrating the serum for thirty to fifty seconds instead of three to four minutes with 5 per cent CO_2 as done by Toribara and his associates, the pH of the residual serum ranges between 7.4 and 7.7 but the range of ultrafiltrable calcium remains essentially the same as reported by us.[8] In conclusion, it can be said that the higher values for ultrafiltrable calcium as reported by Hopkins and co-workers and Toribara and his associates are due to initial lowering of pH of the serum prior to ultrafiltration and we have suggested means to avoid this artefact.[3,8] Although 5 per cent CO_2 is regarded as a physiologic gas mixture, it's true only for whole blood. It is apparent that the pH of separated plasma can be decreased by prolonged exposure to 5 per cent CO_2.

Calcium-protein and calcium-cephalin relationship obeys the law of mass action. From statistical analysis it has been estimated that 1 gm. of albumin appears to bind 0.713 mg. of calcium.[9] Similar analysis in the normals showed that besides albumin, beta globulin also binds calcium.

ANANDA S. PRASAD, M.B., B.S., Ph.D.
Minneapolis, Minnesota

From the Department of Internal Medicine, University Hospitals, University of Minnesota, Minneapolis, Minnesota.

Approximately 50 to 55 per cent of the non-ultrafiltrable calcium is bound to albumin and the rest to beta globulin and cephalin. The ultrafiltrable calcium is freely diffusible in the extra-cellular fluid space and as such is of physiologic importance.

Ninety-nine per cent of the body calcium is stored in bone. Calcium is absorbed from the gastrointestinal tract. A high protein content in diet improves absorption, whereas a high phosphate diet interferes with its absorption. The poor absorption of calcium seen in the malabsorption syndrome associated with Sprue is not well understood. It is only partly due to poor absorption of fat-soluble vitamin D and probably not at all related to the formation of calcium soaps.

Calcium is excreted in the stool and urine. The stool calcium chiefly represents the unabsorbed dietary intake. Neuman and Chen[10] have reported that in dogs, roughly 99 per cent of the filtered calcium is reabsorbed by the renal tubules.

In addition to its role in the mineralization of bone, calcium is also important in neuromuscular physiology. The interrelationship with other ions with respect to neuromuscular irritability can be expressed by the formula:

$$\text{Neuromuscular irritability} = \frac{(Na)\ (K)\ (pH)}{(Ca)\ (Mg)}.$$

It is also important in activating certain enzyme systems such as thromboplastin. The anticogulant effect of oxalate or citrate depends on the binding of calcium ion to prevent this activation.

Ninety per cent of phosphorus in body is in the bone. A 70-kg. man would have a total of 540 gm. of phosphorus and only 54 gm. would be outside of bone. Almost half of the latter is in muscle, where it is an essential feature of the high energy bonds such as phosphocreatine and adenosine-triphosphate. Phosphorus participates in many other functions, such as buffering in acid-base balance.

Phosphorus is readily absorbed from the gastrointestinal tract and about two-thirds of it appears in the urine. Aluminum, calcium, iron, strontium, beryllium and other heavy metals combine with it and prevent its absorption. Normal level in the serum is 3 to 5 mg. per cent. It tends to rise during growth and under influence of an eosinophilic adenoma of the pituitary. It is also elevated in hypoparathyroidism, renal insufficiency and vitamin D intoxication. In respiratory acidosis produced experimentally in dogs, a marked increase of serum inorganic phosphate may depress ionic calcium which in the presence of hyperkalemia cause ventricular fibrillation and cardiac arrest.[11,12] Similar phenomena have been observed in post-hypercapnic patients undergoing major surgical procedures, as reported by Clowes and Simeone.[13] Phosphorus tends to fall after meals, or during recovery from diabetic acidosis, because it enters the cells. It is characteristically low in hyperparathyroidism. It is low in malabsorption syndrome

because calcium is not absorbed and this leads to hypocalcemia and secondary hyperparathyroidism with a phosphate diuresis. Phosphorus is excreted by the kidney and this is influenced by the parathormone.

There are two kinds of cells in the parathyroids, the chief cell and the oxyphil cell. Parathormone has two electrophoretic peaks.[14] There are two schools of thought in regard to the action of parathyroid hormone. One school believes that the hormone acts directly on bone tissue to cause its dissolution and that the electrolyte changes are secondary to the bone changes. The other school believes that the hormone acts on the electrolyte equilibria of the body fluids and that the bone changes, when they occur, are secondary to chemical changes.[15] According to the second school, the parathormone causes phosphate diuresis which tends to undersaturate the body fluids in regard to whatever equilibrium constant governs the serum calcium and phosphorus values. This leads to increased resorption of the calcium-phosphate salt from the bones and causes hypercalcemia and later hypercalcuria. However, Ellsworth and Futcher,[16] in nephrectomized dogs, were able to demonstrate a rise in serum calcium following parathormone administration. Other workers[17,18] were able to produce bone changes in nephrectomized animals with parathyroid hormone. Also the fact that one has osteitis fibrosa in renal insufficiency together with hyperplasia of the parathyroid suggests that the bone lesions are due to parathyroid hormone. It seems likely that parathormone probably produces phosphate diuresis and also has a direct action on bones.

Bone consists of organic matrix and inorganic matter. The matrix is composed of a groundwork of osteocytes and intercellular substances; the inorganic matter consists chiefly of calcium, phosphate and carbonate. The calcium salts of bone and enamel may be represented by the formula $CaCO_3 \cdot 2\ Ca_3\ (PO_4)$ (dahlite). The bone inorganic matter is in the form of crystals, which suggests formation by precipitation and hence the precipitation of the dahlite must be influenced by the calcium, phosphate and carbonate ion concentration of the extracellular fluid. Shear and Kramer[19] have described three steps concerned in the precipitation of calcium salts in the bone. The first step is the precipitation of secondary calcium phosphate ($CaHPO_4$); the second step is conversion of secondary calcium phosphate to tertiary calcium phosphate [$Ca_3(PO_4)_2$] and the final step is the adsorption onto a lattice work of tertiary calcium phosphate crystals of calcium carbonate or possibly of calcium hydroxide. Serum appears to be approximately saturated with respect to secondary calcium phosphate ($CaHPO_4$) and it is probable that the solubility product of this salt governs the levels of serum calcium and phosphorus.[15] The hypothesis as first suggested by Robison[20] holds that alkaline phosphatase, an enzyme made by the osteoblasts, by its action increases the inorganic phosphate locally in bone-forming surfaces, thus favoring dahlite deposition on bone surfaces. However, there is very little organic phosphorus in plasma for phosphatase to act upon. Gutman and Gutman[21] suggested that phosphoric esters formed during glycogen breakdown might serve as substrates for bone phosphatase. It is an established fact that cartilage preparatory to calcification accumulates stores of glycogen which disappear during the course of calcium deposition. Therefore, the immediate cause of calcification may be a localized increase of phosphate ions. This increase may result from the splitting off of inorganic phosphate from organic phosphorus compounds by alkaline phosphatase and for phosphorylase; the substrates for these enzymes to act upon may be built up by the enzyme phosphorylase. This concept has been forwarded by Albright.[15] However, it appears that no agreement has been reached on fundamental questions such as what is the nature of the bone mineral, and what is its solution property or its solubility product. Eisenberger, Lehrman and Turner as quoted by Neuman[22] have concluded that there is no single apatite crystal which will mean that bone is no longer a single phase. If the crystal does not exist as an entity, then neither does such a thing as a solubility product.[22]

According to Albright[15] vitamin D appears to have two independent mode of actions. The first is that it enhances calcium absorption from the gut. The second action is increased excretion of phosphorus in the urine, similar to that of parathormone. As a sequel to increased absorption of calcium from the gut, hypercalcemia results which will decrease the activity of the parathyroids and will thus tend to decrease urinary phosphorus excretion. However, in subjects with hypoparathyroidism, hypercalcemia will not be able to affect the parathyroids and as such the second action of vitamin D, namely the urinary excretion of phos-

phorus will go unabated and thus produces hypophosphatemia. Harrison[23] has reported that two phases in calcium absorption through the gut are present. The initial rapid absorption is probably due to simple diffusion of calcium from the proximal small intestinal lumen into the body fluids dependent on the presence of high concentration gradient. The second phase of calcium absorption represents absorption from the distal intestine. The pH of this portion of the intestine is high enough so that the concentration of calcium in solution is probably very low and absorption at this stage depend on an active transport mechanism requiring cellular activity and it is this phase of calcium absorption which apparently is increased by vitamin D. Harrison[24] has also reported a rise in the serum citrate levels following vitamin D therapy and that the administration of citric acid-sodium citrate mixture made the rachitic cartilage more calcifiable. However, a direct role of vitamin D in the intermediary metabolism of citrate has not been established. Harrison[24] showed that the mode of increased phosphate excretion in hypoparathyroidism following vitamin D therapy depended upon increased glomerular filtration rate whereas parathormone produced increased phosphate excretion by decreasing the tubular reabsorption. At present, it is believed that vitamin D and dihydrotachysterol (AT 10) are not different from each other with respect to their physiologic effects and since great variations in the batches of AT 10 were noted, vitamin D is preferred.

Classification of the Metabolic Bone Diseases
(Albright[15])

1. Too little calcified bone
   - A. Bone formation too little
     - (1) Defect in matrix formation: osteoporosis, osteogenesis imperfecta
     - (2) Defect in calcification of matrix: osteomalacia
   - B. Bone resorption too much: osteitis fibrosa
2. Too much calcified bone
   - A. Bone formation too great
     - (1) Increased matrix formation: elemental phosphorus poisoning, healed osteitis fibrosa generalisata and healed osteomalacia
   - B. Bone resorption too little
     - (1) Osteopetrosis (Marble bone disease)
     - (2) Hypoparathyroidism

It is important to make clear the differences between osteoporosis, osteomalacia and osteitis fibrosa, all of which are characterized by too little calcified bone. In osteoporosis the decrease of bone tissue is due to the fact that the osteoblasts lay down too little bone matrix; that matrix which is laid down is normally calcified. Thus, since osteoporosis is a disorder of tissue metabolism not of calcium and phosphorus metabolism, one is not surprised to find normal serum calcium and phosphorus levels. In osteomalacia there is too little calcified bone due to the fact that there is a disorder of calcium or phosphorus metabolism of such a nature that the calcium-phosphate-carbonate salt is not deposited in the newly formed osteoid. The bony tissue, therefore, is less resistant to stress and strain and this results in an overproduction of osteoid by the osteoblasts. This, in turn, results in a high serum alkaline phosphatase level. In osteitis fibrosa generalisata, there is a decrease in bone tissue as a whole because of increased bone resorption. This leads to decreased bone strength and this, in turn, to an increased activity on the part of the osteoblasts and hence to a high serum alkaline phosphatase level.

Causes of Osteoporosis

1. Defect in osteoblasts
   - A. Loss of stress and strain
     - (1) Atrophy of disuse
   - B. Lack of estrogen
     - (1) Post-menopausal state
     - (2) Congenital hypoestrinism: ovarian agenesis
   - C. Congenital osteoblastic defect
     - (1) Osteogenesis imperfecta
2. Defect in matrix
   - A. Loss of androgen
     - (1) Eunuchoidism
     - (2) ? Senile osteoporosis
   - B. Loss of protein
     - (1) Malnutrition
     - (2) Hypovitaminosis C
     - (3) Cushing's syndrome
3. Defect unknown
   - A. Acromegaly
   - B. Idiopathic osteoporosis

Osteoporosis in man, when due to a systemic cause, has a marked predilection for the vertebrae and pelvis and to a lesser extent, the skull and seldom involves the extremities. The lamina dura around the teeth, as seen by x-ray, is characteristically intact, an important point in the differential diagnosis between this condition and osteitis fibrosa generalisata.

Since the normal stimulus to the osteoblasts is stresses and strains, any enforced immobilization

(flaccid paralysis, plaster cast, et cetera) of all or part of the skeleton will lead to decreased osteoblastic activity and hence bone resorption continuing, to osteoporosis of the parts of the skeleton immobilized. Atrophy of disuse rarely affects the skull and the lamina dura remains intact, in contradistinction to osteitis fibrosa generalisata where the skull is one of the first to show involvement and lamina dura is affected. Atrophy of disuse is probably a factor in the osteoporosis of old age and may complicate other forms of osteoporosis by initiating a vicious cycle; for example, a patient with post-menopausal osteoporosis fractures a vertebra, is immobilized and acquires more osteoporosis. Since in osteoporosis, bone formation decreases and bone resorption continues unabated, hypercalcuria occurs and may lead to renal complications.

Post-menopausal osteoporosis is the commonest of all forms of osteoporosis. Estrogen stimulates endostial bone formation and testosterone enhances this action in pigeons. Similar effect in humans has been observed. A combination of diethylstilbestrol (0.5 to 1 mg. daily) and methyltestosterone (10 to 20 mg. daily) or testosterone propionate (10 to 25 mg. a week, I.M.) gives good results. This treatment can be interrupted for seven to ten days every four to six weeks. A high protein diet is also probably indicated.

Most of the changes of old age are, in the final analysis, due to atrophy; in terms of the skeleton, atrophy is osteoporosis. How much of the atrophy of old age is due to underfunction of the steroid-producing glands, and how much is due to old age *per se* are as yet unanswered questions. In many cases, osteoporosis of disuse, of malnutrition, of the post-menopausal state, and of senility are inseparably superimposed.

The part played by diet in osteoporosis is not well established. A diet inadequate in protein might lead to a negative nitrogen balance and this, in turn, might make it impossible for the osteoblasts to lay down the necessary organic matrix, which is the first step in the formation of bone. The second possibility is that an increased availability of calcium and phosphorus in the system as a result of increases in the diet would decrease the amount of resorption of bone. If such were the case, any primary hypofunction of the osteoblasts would be partially offset by the decreased resorption and the patient would be benefited. Such a hypothesis would explain the apparently beneficial effect obtained by Bauer and Marble[25] and by Adams, Boothby and Snell[26] in the treatment of patients with osteoporosis with diets high in calcium and phosphorus and large amounts of vitamin D. In thyrotoxicosis and long-standing poorly-treated diabetes mellitus, the prolonged use of protein for energy may result in deficiency in some constituent of protoplasm which is needed for bone matrix formation.

Osteoporosis in Cushing's syndrome is believed to be due to anti-anabolic effect of the adrenal steroid on the protoplasmic matrix of bone.

In acromegaly, osteoporosis may be related to hypogonadism which accompanies most cases. The other possibility is that the increased protoplasmic mass in acromegaly requires a higher nitrogen intake to keep in nitrogen balance. Thus there is a relative negative nitrogen balance which may result in too little material for the osteoblasts with which to build bone matrix.

Rickets or osteomalacia can be defined as a state of defective deposition of inorganic materials in cartilage or bone matrix, or both, from any one of the possibilities which will be mentioned.

A classification based on the pathogenesis of rickets and osteomalacia is as follows (Follis)[27]:

1. Disturbance in balance of matrix formation and/or destruction and deposition of inorganic elements.
   - A. Normal rapid matrix formation especially in the premature
   - B. Healing fractures
   - C. Healing scurvy
   - D. Healing osteitis fibrosa
   - E. Marble bone disease
2. Disturbance in absorption of calcium and/or phosphorus
   - A. Calcium
     - (1) Dietary
     - (2) Change in pH of intestinal contents
     - (3) Formation of insoluble complexes (PO_4, oxalate, phytin)
     - (4) Protein content of diet
     - (5) Diarrhoea
     - (6) Steatorrhoea
     - (7) Vitamin D lack
       - (a) Dietary
       - (b) Diarrhoea
       - (c) Steatorrhoea
       - (d) Absence of bile and pancreatic juice
       - (e) Phytin content of diet
       - (f) Impaired formation in skin
       - (g) Increased threshold for effect
   - B. Phosphorus
     - (1) Dietary lack
     - (2) Change in pH of intestinal contents

(3) Diarrhoea
(4) Formation of insoluble complexes (Ca, Sr, Pb, Fe, Al)

3. Excess excretion of Ca and/or Phosphorus
A. Renal disease
(1) Glomerulo-tubular disease
(2) Renal tubular acidosis
(3) Fanconi syndrome
(4) Idiopathic hypercalcuria
B. Lactation and Pregnancy

4. Obscure
A. Vitamin D intoxication
B. Tumor cells in marrow spaces

A few words should be mentioned about Marble bone disease and its association with rickets. It has been recognized that Marble bone disease is associated with rickets in most cases.[27] In this condition there is virtually a complete cessation of destruction of bone. The cartilage matrix impregnated with inorganic materials, plus the organic matrix impregnated with inorganic materials, are not removed. It is important to realize that the body has a tremendous store of inorganic materials which is continuously being made available by normal destruction to be deposited in new matrix, whether cartilage or bone. In Marble bone disease, this inorganic material is locked up in the skeleton. In other words, it is not broken down, and therefore, not released to be deposited in new bone matrix and new cartilage matrix which is being formed and which is ready to calcify. If the amount of inorganic material which can be absorbed is not sufficient, in the face of this lack of the normal turnover which should be present, a marked rachitic change is observed.

In tubular insufficiency, the formation of ammonia by the tubules is impaired. This causes loss of base including calcium which results in low serum calcium. This causes hyperplasia of the parathyroids which, in turn, causes hypophosphatemia. Low serum calcium and phosphorus thus results in osteomalacia. Furthermore in acidosis, the gastric acidity tends to be decreased which would decrease the calcium absorption from the gut. According to Albright these patients respond well to sodium citrate-citric acid mixture and vitamin D therapy.

In chronic glomerulonephritis where both the tubules and glomeruli are affected, a different sequence of events results. Hypocalcemia, as a result of hypercalcuria, induces parathyroid hyperplasia but owing to glomerular insufficiency, phosphorus is retained. High serum phosphorus, in spite of low serum calcium, helps in the deposition of minerals in the cartilage and bony matrix and thus should prevent osteomalacia. In this group, osteitis fibrosa (probably due to secondary hyperparathyroidism) is common.

According to Follis,[27] in chronic glomerular-nephritis in children and in adults, one does find excessive amounts of osteoid and hence the term renal rickets is a justifiable one. There are all gradations, from pure rickets to osteitis fibrosa in chronic renal insufficiency.[27] What the factors are which regulate the type of bone involvement are not known. Perhaps acidosis itself causes renal rickets, as observed in some children with rickets who have no decrease of the serum calcium and no marked decrease of the serum inorganic phosphorus level but who do have chronic acidosis. These patients respond to correction of acidosis alone.[27]

Fanconi syndrome is characterized by a hereditary tendency often accompanied by a family history of consanguinity, impaired growth beginning at an early age, rickets, albuminuria, renal glycosuria, alkaline urine, increased urinary excretion of organic acids, ammonia, phosphorus and calcium, lowering of blood bicarbonate (without azotemia) and degenerative changes in renal tubular epithelium. According to Albright, the acidosis may be due to increased urinary excretion of organic acids. The treatment is the same as in tubular insufficiency.

Vitamin D intoxication may be associated with rickets. The pathogenesis is not clear. Follis[27] postulates that osteoid formation is due to a direct stimulation by vitamin D, as this happens even on a low calcium and low phosphorus diet.

Pathologic evidences have been presented to show that rickets may be associated with leukemia and other malignancies, the pathogenesis of which remains unclear.

A calcium infusion test, as described by Nordin and Fraser[28] may be helpful in differentiating osteomalacia from osteoporosis. Briefly, this consists of giving the patient a four-hour calcium infusion and measuring the urinary excretion of calcium for twelve hours. Patients with osteomalacia excrete less calcium as compared to normals and patients with osteoporosis.

Classification of osteitis fibrosa based on pathogenesis (Follis)[27]:

(1) Acute severe inanition
(2) Acidosis (Local ?)
(3) Primary hyperparathyroidism
(4) Secondary hyperparathyroidism
(5) Hyperthyroidism
(6) Paget's disease
(7) Tumor cells in marrow cavity (Myeloma, leukemia, carcinoma, etc.)

In children who die very rapidly of diarrhea and acute infections, excessive destruction of bone is sometimes seen. In such cases, one finds excessive osteoclastic activity, and histologically one gets the impression that bone is being destroyed in such areas.

Hyperparathyroidism.—The clinical findings in primary hyperparathyroidism can be divided into (1) those due to bone disease, (2) those due to disease of the urinary tract and (3) those due to hypercalcemia, *per se*.

The bone disease when present consists of a generalized decalcification with superimposed cysts and tumors. All degrees of skeletal decalcification are encountered clinically—from the patient with no bone changes to the patient with practically complete loss of skeleton, dying of inability to raise his thorax in respiration. Bone tenderness is a very constant feature. All kinds of bone deformities occur. These include bending of the long bones, deformities of the pelvis similar to those seen in osteomalacia and various deformities of the vertebrae, crushed vertebrae and herniations of the nuclei pulposi through the end plates of the vertebrae. Bones are more brittle in this disease than in osteomalacia so that fractures rather than bending is the rule.

The symptomatology associated with the urinary tract may be divided into three parts: (a) that due to hypercalcuria and hyperphosphaturia, (b) that due to formation of kidney stones and (c) that due to calcium deposits in the kidney parenchyma. Marked polyuria and polydipsia are usually associated with the hypercalcuria and hyperphosphaturia and because of this several times a diagnosis of diabetes insipidus has been made faultily. In association with nephrocalcinosis, renal tubular damage may occur, which adds to the polyuria. Hypercalcemia causes decreased excitability of the nerve-muscle apparatus. Muscles are hypotonic. The lack of tone in smooth muscles may give rise to constipation and sometimes difficulty in swallowing. Calcium deposits in the deep conjunctiva of the palpebral fissure has been noted. These are well visualized by a slit lamp. Band keratitis has also been noted in the superficial layers of the periphery of the cornea and are most marked at the palpebral fissures.

In those cases of hyperparathyroidism associated with bone disease, leukopenia and anemia has been observed. In some the anemia responds to iron therapy.

Cases of hyperparathyroidism without recognizable bone disease do exist. Clinically the cases can be divided in the following four groups:

1. With bone disease and without kidney disease
2. With bone disease and with kidney disease
3. Without bone disease and with kidney disease
4. Without bone disease and without kidney disease

In classical cases, a diagnosis of primary hyperparathyroidism can be established if one finds hypercalcemia, hypophosphatemia with normal serum protein and increased serum alkaline phosphatase. Urinary excretion of calcium on a standard low calcium diet is increased. The phosphorus re-absorption test may be helpful in making a diagnosis in some cases. In certain instances where the serum calcium is normal, in association with abnormal albumin/globulin ratio, a determination of ultrafiltrable calcium, may be of definite value.[8] Often these tests have to be repeated two or three times before a decision can be reached. The above-mentioned investigations should be carried out, once the diagnosis of hyperparathyroidism has been suspected because of the finding of a calcium stone or certain bone changes, or because of certain symptoms suggesting hypercalcemia. The differential diagnosis should include other bone diseases which might be mistaken for hyperparathyroidism and other causes for hypercalcemia:

1. Demineralization due to metabolic bone diseases

A. Osteoporosis: In osteoporosis the serum calcium and phosphorus values with one exception, which will be mentioned, are normal. In early stage calcium and phosphorous excretion in urine are increased but later they tend to be normal or low. Hence, the hypercalcuria and the hyperphosphaturia disappear after the skeleton becomes demineralized in osteoporosis, in contradistinction to hyperparathyroidism where they persist regardless of the degree of decalcification. In osteoporosis, skull is almost never involved, the lamina dura is present and one does not find cysts and tumors in the bones. Only demineralization and deformities or fractures are seen.

In growing children, following extensive immobilization one finds serum calcium to be increased. Serum phosphorus is either normal or slightly elevated and serum alkaline phosphatase is normal. An analogous situation occurs in adults when a person with excessive

bone formation compensatory to increased bone destruction as with Paget's disease is suddenly immobilized.

B. Osteomalacia and Rickets: These characteristically have low serum calcium and urinary calcium excretion is also low. The bones are generally decalcified and lamina dura are absent; however, tumors and cysts are rarely, if ever found, in osteomalacia, and deformities occur as a result of bending rather than fractures.

C. Osteogenesis imperfecta: is an hereditary disease and probably involves all mesenchymal tissue. The osteoblasts fail to form the normal amount of extra-cellular substance. The sclerae are blue. The blood vessels, fascia, periosteum and subcutaneous tissues are all very pliable. When adult life is attained, otosclerosis may develop. The x-ray of the skull will show a very thin but not decalcified skull. The lamina dura is intact. Serum calcium and phosphorus are normal and there is no hypercalcuria or phosphaturia. Serum alkaline phosphatase may be slightly elevated. A family history is positive.

2. There are a few localized bone diseases which may be mistaken for hyperparathyroidism.

A. Polyostotic fibrous dysplasia or Albright's syndrome: This consists of (a) disseminated osteitis fibrosa with segmental distribution suggesting a neurologic or embryologic relationship; (b) areas of cutaneous and perhaps of buccal pigmentation which have a distribution suggesting some connection between them and the bone lesions and (c) sexual and somatic precocity in females but not in the males. The bone lesions may be widely disseminated but are not generalized; the uninvolved parts of the skeleton are normal. The bone lesions are hyperostotic as well as hypostotic; whereas, in hyperparathyroidism hyperostosis is most unusual. Thus in this syndrome, skull x-ray may show a marked increased density at the base of the skull, coupled with a localized increased thickening of the vault of the skull somewhat reminiscent of that seen in Paget's disease. Serum calcium and phophorus values are normal.

B. Paget's disease: The skeletal involvement is localized (i.e. not generalized) and there is a tendency to over-growth of involved bones. Serum calcium and phosphorus values are normal while the serum alkaline phosphatase is elevated.

C. Multiple Myeloma: This can produce a clinical picture which may be difficult to distinguish from hyperparathyroidism except for the presence of abnormal serum proteins and myeloma cells in the bone marrow. Serum alkaline phosphatase is rarely elevated in myeloma.

3. Among the conditions associated with hypercalcemia, the following deserve to be mentioned:

A. Hypervitaminosis D

B. Boeck's Sarcoid

C. Syndrome resulting from prolonged and excessive intake of milk and alkali (also called Burnet's syndrome). The clinical features are: (1) hypercalcemia without hypercalcuria, (2) a normal or high serum phosphorus level, (3) impaired renal function, (4) conjunctival calcium deposits and (5) lowering of the serum calcium level with clinical improvement when the patient is placed on a low calcium diet.

Once the diagnosis of primary hyperparathyroidism is established, the treatment is excision of the offending parathyroid adenoma, if one exists, or enough hyperfunctioning tissue to reverse the abnormalities.

By secondary hyperparathyroidism is meant a state of affairs where because of some modifying circumstance more parathyroid hormone is needed by the body than under normal circumstances. This occurs under the following circumstances: calcium deprivation due to diet, pregnancy, lactation, rickets and osteomalacia, and chronic nephritis.

Commonly, in hyperthyroidism one sees osteoporosis but sometimes one may find osteitis fibrosa. The exact mechanism for the latter is not understood.

Hypoparathyroidism.—The accidental removal of, or damage to, the parathyroid glands in the course of a thyroid operation is, of course, the commonest cause for hypoparathyroidism. Very rarely, hypoparathyroidism occurs idiopathically. There is some association of hypoparathyroidism with moniliasis. There seems to be a tendency for idiopathic hypoparathyroidism to be associated with Addison's disease.

The most striking clinical feature of hypoparathyroidism is the increase in neuromuscular excitability dependent on the hypocalcemia and producing the symptom-complex known as tetany. Other symptoms include: numbness of the extremities, cramps, carpopedal spasm, laryngeal stridor and generalized convulsions. Cataracts are very common. Symmetric, bilateral punctate calcifications of the basal ganglia of the brain tissue are not uncommon. Increased intracranial pressure with bilateral choked disc is another bizarre finding. Multiple ectodermal lesions are also frequently present. Once the condition is suspected from the clinical symptomatology, the diagnosis is confirmed by the characteristic chemical findings, namely, a low serum calcium, a high serum phosphorus, a normal or even low serum phosphatase level and usually absence of calcium in the urine.

Other conditions which cause tetany may be confused with hypoparathyroidism. For practical purposes there are two causes of tetany: hypocalcemia and alkalosis. It has been postulated that alkalosis tetany is due to a decrease in the ionic calcium. Our results in experimental dogs indicate that in respiratory alkalosis the ultrafiltrable calcium decreases only slightly and cannot account

for the presence of tetany on the basis of decrement in the calcium ion.[11] On the other hand, a marked rebound increase in the level of ultrafiltrable calcium in the recovery phase following hyperventilation was observed. This rebound increase in the level of ultrafiltrable calcium may be related to increased citrate in the plasma as reported by Axelrod[29] or to a concomitant decrease in the serum phosphate as suggested by us.[11]

The causes for hypocalcemia other than hypoparathyroidism are rickets and osteomalacia, and renal insufficiency with phosphate retention.

Pseudohypoparathyroidism has essentially the same symptomatology, chemical findings and physical signs as those of hypoparathyroidism, but the cause of the disturbance is not lack of parathyroid hormone but inability to respond to it. The syndrome has, in addition, certain developmental abnormalities, such as round face, thick and short stature, brachydactyly, especially as regards the metacarpal bones and soft tissue calcification.

Satisfactory treatment is achieved by vitamin D and calcium therapy in both hypoparathyroidism and pseudohypoparathyroidism.

Recently cases have been described as pseudo-pseudohypoparathyroidism where the clinical appearance of the patients are those of pseudohypoparathyroidism but serum calcium and phosphorus are normal.[30]

Dispensing Drugs

House File No. 496

BELDIN H. LOFTSGAARDEN
Saint Paul, Minnesota

Presented as testimony at a public hearing in the Commerce Committee of the Minnesota House of Representatives, Saint Paul, Minnesota, March 3, 1959.

AS ATTORNEY for the Minnesota State Pharmaceutical Association, I appear in its behalf in opposition to House File No. 496. This Bill proposes to amend Section 151.01 of the 1937 pharmacy law by adding another definition as Subdivision 14. It defines the term non-habit-forming harmless proprietary medicines. In effect, this definition declares thousands of drugs to be non-habit-forming, harmless proprietary medicines with utter disregard for the true facts and the opinions of the medical and allied professions and of their outstanding authorities in the field of medicine, pharmacology, pharmacy and others who are experts and capable to determine the facts and who are charged with the duties and responsibility of protecting public health and welfare. It also disregards the functions and decision of our state courts.

Who Wants This Bill Passed?

First, the appearance before the Committee of Dr. Fredrick J. Cullen, lobbyist, executive vice president of the Proprietary Association, which he has served for twenty-two years, indicates that the manufacturers of the so-called proprietary medicines are primarily interested in passing this Bill.

Second, the supermarket chain stores known as Red Owl Stores, Inc., and Groves-Kelco, Inc., wholesale distributors, are interested in passing this Bill.

Third, Earl Altnow, vice president of what is known as AMA of Minnesota, Inc. This is not the American Medical Association which many people may be led to believe; it is the Affiliated Merchants Association. It appears to be an organization primarily concerned with passing this Bill. It may be of interest to this Committee to know the viewpoint of Mr. Altnow a few years ago when he apparently was only representing the Minnesota Food Retailers Association as its executive secretary, and published bulletins known as *Minnesota Food Guide*. I have here Bulletin No. 2, Volume 5, of the *Minnesota Food Guide;* let me read from it:

> *Drugs and Drug Sundries.*—We are frequently asked about the items in the drug line that are permissible for sale in other than drug stores. We thought it might be well to restate what seems to be the thinking of most of our retailers.
>
> *Drug Sundries*—The toothpastes, toiletries, shampoos, et cetera, are the rapid turnover items in which so much interest is shown and on which so many of our retailers are doing an excellent job. These are the items that are highly recommended for food store sale.
>
> *Drugs* as such should properly be dispensed by qualified technicians. We, as food retailers, are not qualified as pharmacists and, in most cases, readily concede that we are not interested in dispensing drugs. True, there are two or three items which develop a fair volume for which some of our people do have some requests—aspirins, cough syrup, and the like. Perhaps it may seem unimportant to make an issue of these comparatively minor items, but the line must be drawn somewhere, and under the law, such things cannot be sold in a food store. It seems to be the consensus of opinion that as food folks, our sole interest lies in the sale of sundries not drugs. This adds up from a profit standpoint as well.

Fourth, the author of the Bill, Jack Peterson, is interested in passing it. Last week at the hearing before this Committee, he made the statement, "I carried around in my pocket freak bottles of medicine. I do have two bottles of medicine with me this morning. One is labeled cough syrup, the other is labeled vitamins." The Supreme Court in Culver vs. Nelson established that "vitamins" was drug and medicine and not a harmless non-habit-forming proprietary medicine. The label also shows that these medicines are distributed by Pioneer Tea Company of Duluth. Jack N. Peterson is president of the Pioneer Tea Company. May I state that our pharmacy law provides that anyone who sells

drugs and medicines without a license is guilty of a crime. I am also informed by the pharmacy board that neither Pioneer Tea Company nor Jack N. Peterson is licensed to sell drugs and medicines.

Their principal propaganda and statements to the public are that they are interested only in selling harmless home remedies, cosmetics and beauty aids, and not in selling drugs and medicines and that public health is not involved. It is not necessary to amend the pharmacy law in order for them to do what their propaganda claims they want to do. The pharmacy law, among other things, imposes upon the pharmacy board the powers and duties to (1) regulate the practice of pharmacy; (2) to regulate the sale of drugs, medicines, chemicals and poisons, has this proviso:

> Nothing in this chapter shall apply to or interfere with the manufacture, wholesaling, vending, or retailing of non-habit-forming harmless proprietary medicines when labeled in accordance with the requirements of the state or federal food and drug act; nor to the manufacture, wholesaling, vending, or retailing of flavoring extracts, toilet articles, cosmetics, perfumes, spices, and other commonly used household articles of a chemical nature, for use for non-medicinal purposes.

It must be noted that by this act the pharmacy board cannot in any way interfere with any sale of non-habit-forming, harmless proprietary medicines. You will also observe that in order to clarify, some other items (which the drug stores practically exclusively used to sell) come under this exemption as clarification. It provides "nor to the manufacture, wholesaling, vending, or retailing of flavoring extracts, toilet articles, cosmetics, perfumes, spices, and other commonly used household articles of a chemical nature, for use for non-medicinal purposes."

And yet, the propaganda sheets of the Affiliated Merchants Association indicate and lead people to believe that the pharmacy board and drug stores are trying to deprive grocery stores from selling toothpaste, cosmetics, perfumes and other beauty aids. However, their real purpose in passing this Bill is to be permitted to sell drugs and medicines irrespective of whether or not they are non-habit-forming, harmless proprietary medicines and with immunity from liability and without concern to public health. Profits and financial gains are their only motives.

At the hearing before this Committee last week, there was displayed a large cardboard with the name of about eighteen drugs and medicines the author of the Bill claimed were among the drugs and medicines they wanted to sell as harmless non-habit-forming home remedies. Let me give you a brief history of facts relating to court actions involving these drugs and medicines. The pharmacy board with the endorsement of the pharmaceutical association, adopted rules and regulations which prohibited the sale of drugs and medicines by self-service method, and prohibited the sale of any drugs and medicines to any customer of any package to which such customer might have helped himself. Certain drug store chains refused to comply. In the interest of public health, the pharmacy board refused to renew their annual licenses. Two of these firms brought action in District Court of Ramsey County to compel the issuance of licenses and to permit them to sell drugs and medicines by the method of self-service. The pharmaceutical association intervened and I, as its attorney, took part in the proceedings. After taking depositions, the chain stores moved for summary judgment which the court denied. Then these two drug store chains were joined with a third drug store chain and commenced an action in Federal Court in an endeavor to accomplish the same thing. From an adverse decision to them, they appealed to the Court of Appeals at St. Louis and were again defeated. They then agreed to comply with the rules and regulations of the pharmacy law, revamped their stores and removed drugs and medicines from self-service and their licenses were renewed. Then the State of Minnesota, in behalf of the pharmacy board, commenced an action against the Red Owl Stores, Inc., which were selling drugs and medicines at both wholesale and retail in their own stores and to a large number of associate stores, in direct defiance of the request of the pharmacy board to desist, and without complying with any of the provisions of the pharmacy law. The Minnesota State Pharmaceutical Association was permitted to intervene.

Action was also commenced against Groves-Kelco, wholesale house, who was selling these drugs and medicines to the retail stores for resale in violation of law. Defendants answered denying they were selling drugs and medicines and if the items were drugs and medicines they were harmless non-habit-forming proprietary medicines and were exempted from the pharmacy law. They also claimed other defenses on constitutional grounds. In preparation for trial, the plaintiffs took the deposition of Dr. T. B. Magath of Mayo

Clinic at Rochester, Minnesota. Dr. Magath is recognized as an outstanding authority in medicine and pharmacology, and will address your Committee at this hearing. The defendants were represented by several lawyers and also by one known as Dr. Condon from Miles Laboratories. It was, of course, necessary for plaintiffs to prove that these items were drugs and medicines. Dr. Magath first was questioned and testified as to Alka Seltzer. He was cross-examined by the defense lawyers coached by Dr. Condon of Miles Laboratories. After the completion of the testimony on the subject of Alka Seltzer, the defendants asked for a recess. The defense lawyers had a conference and then stipulated into the records that all the eighteen items were drugs and medicines. Since Dr. Magath was leaving for Europe and unable to be present at the trial, we proceeded to question him as to whether or not these eighteen items of drugs and medicines were harmless. Dr. Magath testified that none of the eighteen drugs and medicines were harmless. We then questioned him on whether or not they were non-habit-forming. He testified that six of the eighteen were non-habit-forming, but the others were not non-habit-forming. In other words, they were habit-forming. He also testified that none of the eighteen drugs and medicines were proprietary medicines. At the time of trial, it was stipulated into the records that the eighteen items involved were drugs and medicines; that defendants had not complied with the requirements of the pharmacy law entitling them to be authorized to sell drugs and medicines; it was also stipulated that six of the drugs and medicines were non-habit-forming.

The defendants raised the issue that the pharmacy law contained no provision for injunctive relief but contained a criminal provision for violation of the law and, therefore, the only remedy available was criminal prosecution and trial by jury. The court denied defendants' request for trial by jury upon the grounds that public health was involved and the court had the power and authority to grant injunctive relief. The court further determined that the defendants had the burden of going forward with the proof that the drugs and medicines were harmless non-habit-forming proprietary medicines. At the trial, the eighteen items of drugs and medicines, together with the labels thereon, were introduced in evidence. Evidence was also introduced showing a continuous widespread sale of these drugs and medicines in defiance of law. Plaintiffs rested. Defendants failed to introduce any testimony in support of their defense that the drugs were harmless non-habit-forming proprietary medicines. The lower court found for defendants and held that (1) plaintiffs were not entitled to injunctive relief on the grounds that the pharmacy law had no provisions for injunctive relief, (2) that the only available proceeding was prosecution under the penal provision and trial by jury, (3) also held, in effect, that the defendants did not have the burden of going forward with the proof that the drugs were harmless non-habit-forming proprietary medicines.

Plaintiffs appealed to the Supreme Court. State of Minnesota vs. Red Owl Stores, Inc., and Groves-Kelco, 92 NW 2d, 103. The Supreme Court reversed the lower court and held (1) that the burden of proof to show that the drugs and medicines were non-habit-forming, harmless proprietary medicines rested on the defendants; (2) that this involved public health and welfare and therefore no provision in the law for injunctive relief was necessary to grant injunctive relief; (3) that plaintiffs had established a prima facie case and were entitled to injunctive relief; (4) that with respect to whether or not public health is involved, (a) "the uncontrolled sale of drugs and medicines in inimical to public health; (b) it must be conceded that the subject of public health is deeply involved with the sale of all drugs;" (5) that whether or not it was proper to proceed with an action to stop unlicensed stores from selling these drugs and medicines, "We think that under the circumstances it was the duty of the Attorney General, as agent of the state, to institute injunctive proceedings to accomplish that purpose;" (6) that a new trial should be granted.

The court set February 7, 1959, as the date for retrial of the case. Defendants, upon motion, asked for a continuance until after the legislative session on the grounds that the president of Red Owl Stores, Inc., had been elected a member of the State Senate and the case was reset for trial May 6, 1959. In the retrial of the case, the defendants are afforded an opportunity to come into court and offer proof, if they can, that these drugs and medicines are harmless non-habit-forming, proprietary medicines. If the defendants are successful in proving that any one or all of these drugs are harmless non-habit-forming, proprietary medicines, then any and all such items so-proved will be

exempt and may be sold without control of the pharmacy board. In this manner, the decision of the court will be based upon the evidence produced concerning each drug and medicine. Doctors, pharmacologists, chemists, pharmacists, and any qualified person will be available to testify as to the ingredients, the purpose of the drug, the effects upon the human system and as to whether or not these drugs are or are not harmless non-habit-forming, proprietary medicines. When so-determined by the court, it will settle the issue in a proper proceeding according to law.

Why should the Legislature, without the benefit of expert testimony on each and every drug item, arbitrarily determine and declare that these eighteen drugs and medicines, including thousands of other drugs and medicines, are non-habit-forming, harmless proprietary medicines. A reading of the Bill indicates three things that determine drugs and medicines to be harmless, non-habit-forming proprietary medicines: All non-prescription medicines (1) which are safe when used according to the directions upon, or accompanying, the package or bottle (Both non-prescription and prescription drugs, including strychnine, technically qualify under this part of the Bill); (2) which are advertised or sold directly to the general public under the trade name or registered trade mark of the manufacturer or distributor (There isn't anything in this part of the Bill that can possibly determine or make the drugs and medicines harmless non-habit-forming); (3) and specifically including items that have been designated by the board for sale in stores registered under the provision of Section 151.26. This refers to drugs and medicines which are not exempted in the present law as harmless, non-habit-forming drugs and medicines and by this part of the definition, it changes the drugs to harmless, non-habit-forming by the board designating them for sale in licensed stores according to law. The proponent's statements that these eighteen drugs and medicines are harmless, non-habit-forming home remedies and that no proof has been made that they are harmful, is a false statement and briefly I shall submit some of the proof. The Supreme Court in State vs. Zotalis, 172 Minn. 132, determined that aspirin was not a harmless non-habit-forming drug and medicine.

I also want to call your attention to *U. S. Vital Statistics of 1950:* "aspirin poisoning ranks next to barbiturates and petroleum products poisoning." Also the report of Jerome Trichter, Assistant Commissioner of the New York City Health Department, before New York State Joint Legislative Committee on September 20, 1956 said:

> In New York City from January 1956, through September 1956, there were 3,356 cases of poisoning reported to the City Health Department from household drugs and chemicals. Of these 3,356 cases, 1,552 cases occurred in children under fifteen. Even such a common drug as aspirin . . . accounted for 364 cases of poisoning reported in this nine-month period to the Health Department. Of these 364 cases of poisoning, 278 were in children under fifteen and the balance of eighty-six were in adults . . . this group of cases included four deaths, two in adults and two in children.

How about Bromo Seltzer? In the Red Owl case, the Supreme Court called attention to the label containing the following caution:

> Do not exceed two doses in twenty-four hours. In persistent or frequent headaches, Upset Stomach or Neuralgia, consult your physician. Not for use by children; if rash, drowsiness in daytime, or any unusual symptoms occur, discontinue use at once. Not for use by those having kidney or other organic disease, unless advised by physician. Do not exceed recommended dosage; overly frequent and continuous use may result in serious effects.

From this label, it appears that this drug is so harmful and dangerous that it must not be used by children, which of course includes teen-agers. Anyone having kidney or other organic disease apparently should not use it unless prescribed by a physician. Overly frequent and continuous use may result in serious effect.

These are the type of drugs and medicines that this Bill proposes to declare, by law, as harmless non-habit-forming proprietary drugs and medicines. If these drugs and medicines are harmless non-habit-forming proprietary, then why don't the manufacturers so state upon the label. It is quite apparent that the manufacturers know that such a statement would be false, otherwise it would be so-stated on the label. Instead, the proponents ask the Legislature to falsely declare, by law, that these drugs and medicines are harmless, non-habit-forming, proprietary medicines in order that the same may be sold by supermarket chain stores, grocery stores, restaurants, taverns, filling stations, by peddlers and vending machines, or by anyone at any time and at any place without control or regulation of the pharmacy board or anyone else and without any regard for public health.

Childbirth After Pneumonectomy

H. F. R. PLASS, M.D.
Minneapolis, Minnesota

Presented before the Minneapolis Society of Internal Medicine, January 21, 1959.

SINCE pulmonary surgery has been applied in chest diseases, a number of young women in the child-bearing years have been rescued from their illnesses and returned to their families with only one lung remaining. The question of their ability to bear children arises and should be answered as wisely and clearly as possible. Much of the rehabilitation of the chest patient depends upon regaining self-confidence, and in the young woman, much of it will revolve around her ability to raise a family. We have seen two patients complete two pregnancies sucessfully after total pneumonectomy.

Review of the literature shows records of ninety-seven women successfully delivering 117 children after pneumonectomy. The first of these patients was reported in 1950.[1] In 1953,[2] twelve more were reported; in 1954,[3] an additional four. Laros[4] in his study of all the cases in the Netherlands, reported in 1958 on sixty-four women who had a total of seventy-four children after pneumonectomy. This seems to be the total experience recorded. In all, there were ten fetal deaths and no maternal deaths.

Report of Cases

Our *first patient* had her right middle lobe and right lower lobe removed because of bronchiectasis in 1940. Continuing productive cough and hemorrhage led to removal of the remainder of the right lung in October 1944. Marked herniation of the left lung through the superior mediastinum into the right chest cavity followed the procedures. She had symptoms of precordial pain, dyspnea, and numbness in the left arm for about a year. Lasting longer were symptoms of obstruction to swallowing. This was shown by barium examination of the esophagus by fluoroscope and x-ray films to result from a constriction at the level of the clavicle. The mediastinum was found shifted into the right chest, with the esophagus to the right of the trachea and dilated above the constriction. The question of right thoracoplasty was entertained in order to relieve these symptoms of traction, but this never was carried out.

In April 1946, the patient was found to be pregnant. She was twenty-nine years old, her vital capacity was 2200 cc. in four seconds, 1900 cc. in 2.4 seconds, and her general condition seemed improved. Her life was not felt to be threatened by the pregnancy and she was followed closely. Two previous pregnancies had terminated with normal deliveries and the third one was completed equally uneventfully. There was no rise in her normal venous pressure and breathing capacity was unchanged. A coincidence during this pregnancy after pneumonectomy was total relief from all symptoms related to her shifted mediastinum. She has had three attacks of pneumonia in the left lower lobe during the past twelve years, but no other major illnesses.

Our *second patient* was first seen when she was twenty years old in 1949. She also presented a long history of bronchiectasis which probably started in her infancy. At age seventeen she had the left lower lobe removed, and a year later, the lingula. Despite this, she continued to have fever bouts when first seen, with temperatures of 101° to 104° occurring one or two days a week. Such episodes were associated with increased amounts of sputum which otherwise measured two ounces or less each day. When she was febrile, her sputum was foul; it always was purulent and highly tenacious with a gelatinous consistency. At her initial examination, a loud second pulmonic heart sound was noted and a presystolic apical crescendo murmur. A small non-toxic goiter was present, and coarse, shifting rhonchi were always heard over the remaining lung tissue. It was feared that her pulmonary venous pressure was high and that she might tolerate further surgery poorly.

After a month of observation she had the remaining portion of the left lung removed and an extensive thoracoplasty. For the first two months after this she was

well, but then she began to raise more sputum than before, and again had bouts of fever. Penicillin therapy provided only one week of relief; nevertheless, it was continued. The penicillin did alter the color of the sputum from green to yellow, but the amount remained more than two ounces daily. Re-examination now revealed about the same findings on the right, with the addition of some retraction of the interspaces on inspiration. Bronchoscopy showed the trachea to be flattened in the antero-posterior direction, apparently due to the softening of the cartilages.

Another intrathoracic procedure was undertaken to try and increase the tracheal lumen and stabilize it. Bronchoscopy several months later showed no great change. Terramycin was started in 1950 and was continued, but the patient continued to have much respiratory distress with cough, clear sputum, and dyspnea at rest. Her vital capacity increased from 1.5 l. (liters) to 1.8 l. in the first year after the tracheal stabilization. Postural drainage was prescribed but never well carried out. Tracheal aspiration was done twice a week for the next several years. She tended to take the Terramycin fairly continuously but was limited by the diarrhea it produced. Her usual schedule was 1 gm. per day, four days a week. There was an episode of enlargement of the liver which was thought to be due to congestive heart failure.

In 1952, because of physical signs and the already high metabolism, thyrotoxicosis was diagnosed and treated with propylthiouracil. She had had constant tachycardia, which had increased, and her weight had fallen to an all-time low. The results of therapy were good enough so it was continued for two years.

While taking Terramycin she developed a mastoiditis which had to be treated surgically. The infecting organisms were resistant to antibiotics. She had repeated attacks of purulent sinusitis, some of which responded to sulfonamide therapy. Because she had used Terramycin steadily for four years, three or four days every week, it was withdrawn—not without considerable protest from the patient. In late 1954, the propylthiouracil was also stopped.

The diagnoses at this point were: absent left lung, bronchiectasis and emphysema of the right lung, mitral stenosis, chronic pansinusitis, hay fever, asthma and migraine. She had gone through two periods of moderate depression during observation. The hay fever and asthma had been difficult to diagnose in the presence of so much suppurative disease. Nevertheless, desensitization therapy was begun, and as it was continued, it was evident that there were fewer episodes of infection. As one might presume, as the allergic state of the respiratory mucosa was reduced, there was less secretion of thick mucus and, in turn, less bronchial and sinus ostium plugging and obstruction. The tracheal aspirations gradually were eliminated after having been done twice a week for five years. She had no respiratory infection in 1955 requiring therapy.

In May, 1956, she married. In April 1957, she became pregnant and after consultation it was agreed that she seemed well enough to survive the pregnancy, if elaborate precautions were taken to protect her against pulmonary and cardiac overload. Her vital capacity was found now to be 2.0 liters. Her weight at the beginning of pregnancy was 118 lbs, some 15 lbs. more than it was with the thyrotoxicosis. At delivery, her vital capacity remained 2.0 l., her weight reached 138 lbs. and in the last trimester her pulse rose to 120 when taken in the resting state. Her resting respiratory rate (seated) was 20 to 24 per minute. There were no other signs of pulmonary or cardiac distress, even at the theoretical time of peak load and maximum blood volume at seven months gestation.

Delivery was accomplished by Cesarean section in December 1957, at thirty-six weeks of gestation, without difficulty, under local anesthesia. Pentothal (a few cc.) was given to make her sleep during the extraction of the baby; and she awakened before the skin was closed and was out of bed the next day. No curare was permitted.

During the past year she has had another attack of sinusitis and otitis which cleared up in four weeks under treatment with penicillin and sulfadiazine. Beta hemolytic streptococci were cultured from the throat at the onset. She continues desensitization therapy and has only minor asthma and hay fever.

Summary

Ninety-seven women have been reported in the literature as having borne 117 babies after total pneumonectomy. Two more successful cases are reported, one with complicating mitral stenosis, asthma and emphysema. Probably many times as many deliveries have occurred as have been reported. Pregnancy and delivery are accomplished successfully in these women—usually *via* a low forceps delivery after normal labor. In our second case, operative delivery seemed required because of impending cardiorespiratory decompensation. Very few operative deliveries are reported to be required. After observing these patients, we feel reinforced in the belief that pregnancy and delivery are such normal events that they usually can be tolerated even by a woman with only one lung. The reproductive careers of such women should be determined by their prospects of living to raise the children they bear.

ANTIHYPERTENSIVE AGENTS

II. Five Commandments for Proper Use

The following commandments, if diligently practiced, will help prevent commonly committed sins in the use of antihypertensive agents.

1. Thou Shalt Evaluate Thy Patient Before Treatment Is Started

Every patient who is a candidate for antihypertensive therapy deserves careful study to (1) rule out causes for secondary hypertension, such as pheochromocytoma, coarctation of the aorta, aldosteronism, Cushing's syndrome and unilateral renal disease, (2) evaluate the status of the cardiovascular and renal systems and (3) establish pretreatment levels of blood pressure. When these fundamental rules are ignored, pheochromocytomas may go unrecognized, potentially curable hypertension is not discerned, and injudicious use of potent drugs may aggravate coronary, cerebrovascular or renal insufficiency.

One or two casual determinations of blood pressure in the physician's office can be extremely misleading with respect to the severity of hypertension. If it is impractical to measure the resting blood pressure, either in the hospital or at home, numerous readings should be made in the office on several different days, preferably by a nurse or a technician. An obvious exception to this deliberate method of evaluation occurs in severe hypertension (group 3 or 4) with impending complications, in which delay of therapy is neither necessary nor advisable.

2. Thou Shalt Treat Thy Patient With All Thy Might and All Thy Skill

Once the decision in favor of medical treatment has been made, the treatment should be pursued until the blood pressure is brought under satisfactory control or until the patient cannot tolerate effective doses of the medicaments, no matter how artfully they are combined. Insofar as is presently known, no virtue is to be derived from ineffective doses of hypotensive drugs. If the blood pressure is not reduced, treatment is a failure and should be appropriately modified or abandoned. The immediate goal of treatment is normotension or as near to it as the patient and his cardiovascular and renal systems can safely tolerate.

3. Thou Shalt Not Abandon Effective Therapy

Despite the rapid advances made in the field of antihypertensive therapy in the past ten years, clinicians still do not have a drug that cures hypertension. This means that medication must be continued indefinitely if the blood pressure is to be controlled. It is a grievous but unfortunately common error in the treatment of hypertension to discontinue medication when the blood pressure becomes normal, for almost inevitably it will increase again when medication is withdrawn.

4. Thou Shalt Not Become Encumbered by Combination Tablets

Although combinations of drugs frequently are employed for adequate control of hypertension, the use of single tablets that contain combinations of drugs is to be deprecated, for this deprives the physician of his ability to make precise adjustments in the dose of one agent without simultaneously changing that of others. Pharmaceutical houses are adding to the understandable confusion in the field of hypotensive drugs by glutting the market with tablets containing two or more ingredients and bearing proprietary names that often conceal this fact and that have no intelligible significance insofar as the drugs contained therein are concerned. I refer to such anomalies in nomenclature as "diupres," which contains diuril and reserpine (not apresoline, as might be anticipated from the name), and "mio-pressin," which contains phenoxybenzamine hydrochloride (dibenzyline), protoveratrine and the whole root of Rauwolfia (who would have guessed?); other examples are protalba-R, unitensen-R, veralba-R, elserpine-prab, rauprote and rauvera, which are a few trade names of preparations that contain a combination of derivatives of Veratrum and Rauwolfia. Is it any wonder that patients sometimes receive derivatives of Rauwolfia in several different tablets taken simultaneously and innocently prescribed by a busy practitioner who cannot decipher the jargon of polypharmacy?

Drug companies rationalize this situation by declaring that it is cheaper for the patient to take

his medicine combined in a single tablet. This is true only for the occasional patient whose hypertension fortuitously is controlled best by therapy with drugs in the exact proportion contained in a single tablet. However, just as most men can be fitted best with clothes that are custom-tailored, so most hypertensive patients fare better if their regimen is tailored individually by an attentive physician and not fashioned wholesale by a remote drug house. In such cases, the economy of combination tablets is false, because, when the dose of one ingredient is optimal, the dose of the other is necessarily either inadequate or excessive. These discrepancies are compounded when tablets contain three different drugs. Manufacturers of drugs and some physicians fail to realize that the therapeutic requirements of hypertensive patients may change from time to time, with regard to both the type of drugs and the proportions of their doses. Combination tablets fail to meet this changing need.

In my opinion, the only legitimate indication for using such tablets is for the patient who has an aversion to taking medicine and who reckons dosage in terms of the number of tablets consumed rather than their contents. In such cases, one is justified in trying to get in as much medicine per tablet as is possible.

The physician should not forfeit to drug companies his right to adjust the doses of the drugs precisely and to individualize regimens.

5. Thou Shalt Follow the Hypertensive Patient as Long as Ye Both Shall Live

Although it may be debatable that all hypertensive patients should be treated, there can be no argument that all such patients do deserve careful medical attention and observation. The physician must assume the responsibility for close surveillance of those patients to whom he denies specific hypotensive therapy so that progression of the disease can be recognized and appropriate treatment instituted before irreversible complications develop.

Effective treatment with hypotensive drugs demands frequent observation and regular determination of the blood pressure. Weekly, if not daily, visits will be necessary at first until a satisfactory regimen is constructed. Thereafter, it is advisable to see the patient who is taking antihypertensive drugs at least once a month. In this way, one can be assured that the hypertension is remaining under good control, that appropriate adjustments in dosage can be made, and that late side effects can be detected before serious harm results. Constant and sympathetic attention from a solicitious physician may prevent a disgruntled and unhappy patient from abandoning effective therapy because of annoying side effects.

The unreasonable and illogical prejudice that some physicians hold against the determination of blood pressure at home is frequently a disservice to the patient. A successful antihypertensive regimen in this enlightened age depends to a large extent on taking the patient into partnership in the endeavor. In this cooperative effort, the patient is entitled to know his blood pressure, whether it be taken in the physician's office or at home. Most patients whose hypertension is severe enough to require the use of ganglion-blocking agents doubtlessly will fare better if they take their own blood pressure at home and are taught to adjust their doses of medicaments according to these readings. Except in rare cases, this does not lead to anxiety and obsessions as claimed by some physicians; to the contrary, it allays anxiety when the patient sees his blood pressure coming down and he realizes that his hypertension can be treated effectively. Opposition to the measurement of blood pressure at home frequently arises from the physician's anxiety (not the patient's) about his ability to treat hypertension satisfactorily.

L'Envoi

These, then, are the commandments for proper use of antihypertensive agents. Ignore them, and thou shalt surely fail; keep them, and the numbers of thy grateful hypertensive patients shall surely increase.

RAY W. GIFFORD, JR., M.D.

MEDICINE'S GREAT NEED

A Little Bit of Empathy

Empathy—"the entering into the feelings of another person"—is a word which has been brought to the attention of physicians in the past few years. Recent teachings have exhorted physicians to avoid the use of empathy in their practice of medicine, stating in effect that the patient must be treated objectively and as a physiologic whole. The physician must remain aloof from the sharing of any of his patients' emotional situations, stresses and problems. Without a doubt such a thesis is by

far the more comfortable way to practice medicine, but where is it leading us?

Today, we physicians in America are fast becoming an isolated group surrounded by an ever-increasing tide of socialized medicine. Yet, throughout the world, the adherents to the socialization of medicine among the medical profession itself will often admit that the life of a socialized physician is an easier one certainly than that which they had previously led. The association with the patient is much more objective and in most instances hours of work are prescribed. In many of the larger clinics in the larger cities, the patient has no attachment to any one physician, but is required to accept whoever is available at the hour at which he arrives. All fees and charges are set by law or regulation so the physician is devoid of any financial concern. In talking with a Swedish physician not long ago, I realized that as one rises higher in this hierarchy of socialized medicine this disassociation from the patient becomes even greater. The higher specialist chooses only those patients whom he wishes to see, not necessarily those who wish to see him.

What then is driving the patient to support socialized medicine? Does not much of the blame stem from our own actions, wherein we, as free practicing physicians, are setting up, in effect, the conditions under which socialized medicine thrives: namely by strictly limiting our hours of practice especially in the specialties; by adhering too strictly to rigid fee schedules; and by giving less of ourselves to our patients. Today, there is not a specialty group in any local medical society that does not have its own relative-value fee schedule, which, in itself, is a justifiable document very necessary for the protection of the individual physician against those large interests who would be willing to take an unfair advantage of the private physician. However, I was appaled, when attending one of the committee meetings of our local medical society, with the number of petty patient-physician grievances over charges, some involving no more than $2.00. In each instance, the physician was entirely within his rights according to the adopted relative-value fee schedule of that particular specialty society. However, when it is held up as an unbending yardstick against the individual patient, that individual will soon be lost to the cause of private medicine, especially if that physician is equally unbending in his willingness to see the patient during any but very prescribed hours.

Today, the number of private practicing physicians who are willing to make house calls is steadily decreasing. Physicians are demanding their free time, uninterrupted, without adequate considerations of the feelings of the patient, whether the patient be physically sick or emotionally ill. All of this stems from the philosophy of regarding our patients on a purely objective basis and as a physiologic whole. This, of course, is scientifically adequate, but with it we are overlooking one major premise; to wit, we are dealing with our fellow human beings. They have emotions and problems which must be shared to some extent by the physician, that person in whom they place their confidence. They must be assured of his continued interest and that he is not just someone who will see them one day and then pass them on to another physician the next day.

Less than two centuries ago our country was established after a long and bitter struggle on just such principles of free enterprise and the rights of the individual. Now, from without our own boundaries, these rights and liberties are being insidiously attacked from every angle. As physicians, the socialization of the practice of medicine is our concern. We are not going to maintain these rights and privileges unless we can convince the public at large that this is the better thing for them and can give the public the type of medical service they desire not merely the type of medical practice we might wish for them. Any enterprise worth its salt is worthy of the effort that goes into it, and we, as private physicians, are going to have to put forth that effort to maintain our status of private enterprise. We cannot look askance at satisfying our patients. We must be willing to see and treat our patients cheerfully during their illnesses. We must be able to individualize and evaluate the financial abilities of our patients and not allow our relative-value fee schedule become our hard and fixed rule. We must have a sympathetic feeling for each and every patient and attempt to understand his needs and problems. In short, we must have a bit of empathy.

L. Clagett Beck, M.D.

THE GHOST INTERNIST

A few years past the ghost surgeon was a popular point of discussion. He was the individual who through prior arrangement with his associates entered the operating room and performed surgery without the patient's awareness of his existence. The attending physician then left his patient with

the impression that he had been the surgeon in charge of the case. The attending physician either paid the ghost surgeon directly or some "under the table" method of remuneration had been arranged. Fortunately, these few individuals have been eradicated. It was recognized by the medical profession that these individuals served no useful purpose either professionally or personally to either the patient or the attending physician.

Unfortunately, the ghost internist "still exists." He is usually a resident in training or in some instances even an intern who may profess an interest in Internal Medicine. Certain of the attending staff physicians in the Hospital, under the guise of assisting the young physician, turn over to him their medical cases for diagnosis and management. The training of these young men and young women must be under the jurisdiction and personal supervision of people qualified in Internal Medicine. Unfortunately, the "ghosting" is usually done by people unqualified in Internal Medicine. It is simply a means by which they obtain "a complete medical work-up" and special care for their patient from the house staff.

There is no complaint relative to the complete study and care of a patient by the resident or intern as long as it is supervised by a qualified person. It is strictly dishonest and it serves no useful purpose to either the patient or the attending physician if such a study is not supervised by a trained internist. It is the implicit responsibility of the Intern Resident Committees to be certain that the resident and intern is not being prostituted by staff men who follow this custom. Since "ghosting" in Surgery served no useful purpose and was recognized as contrary to the best philosophy of the care of the patient so "ghosting" in Internal Medicine serves no useful purpose and should be abolished.

J.F.B.

SOCIAL SERVICE

Medical Report

The patient, D. M., was admitted to the University Hospitals on September 7, 1954. He had been in an automobile accident on April 18, 1954 and sustained a compression of the body of T12 with dislocation of T11 on T12 with resultant complete motor and sensory loss of both lower extremities and transverse fractures of the mid-shaft of the right tibia and fibula. He was taken to Municipal Hospital in Long Prairie, where he was treated by trunk sling suspension and leg traction followed by application of a cast to the right leg. He remained incontinent of urine and feces.

The patient was discharged to his home in a wheel chair on July 20, 1954. Here he sat for a whole week because his mother said she had no bed for him and was afraid to move him. He was readmitted to the Municipal Hospital on July 28, 1954, with a recurrent urinary tract infection and a sacral decubitus ulcer. Another ulcer over the left great trochanter developed shortly afterward.

Previously, on June 29, 1954, the patient's local physician had requested transfer to the Neurosurgery Service of the University Hospitals through the Todd County Welfare Board. Apparently because of the length of time which had elapsed since the patient's injury, surgical intervention was not indicated. Consequently the patient was placed on the waiting list on July 28, 1954, for a bed on the Physical Medicine and Rehabilitation Service and was transferred September 7, 1954, from the Municipal Hospital in Long Prairie.

Physical examination revealed a seventeen-year-old boy with a complete paraplegia. There was a sensory and motor level at T12. The patient was incontinent of urine and feces. There was a large infected sacral decubitus ulcer about 10 centimeters in diameter and 2 to 3 centimeters deep. Another pressure area 1 by 4 centimeters overlay the left greater trochanter. There was a gibbus deformity of the spine at T12 and the right leg was in a posterior plaster splint. Both ankles and feet were moderately edematous. The lower extremity musculature was moderately atrophic. There was bilateral drop foot and tightness of the left gastrocnemius muscle. Abdominal reflexes were absent in the left upper and lower quadrants. Knee jerks were hypoactive bilaterally as was the left ankle jerk. The right could not be tested.

The hemoglobin was 14 grams per cent, the white count was 16,000 with 76 per cent neutrophils and total serum protein was 7.2 mg. per cent with an A:G ratio of 3.1 to 4.1. The urine contained red cells, white cells, albumin and numerous bacteria which on culture were Aerobacter aerogenes and a Proteus species.

X-ray examination revealed an old compression fracture of T12 with anterior subluxation of T11 on T12, and a healing fracture of the mid-shaft of the right tibia and fibula. There was diffuse osteoporosis of the pelvis and bones of the lower extremities. An intravenous pyelogram demonstrated a urinary tract which appeared normal. Cysto-

scopy and cystometry revealed a spastic neurogenic bladder with a capacity of 200 centimeters.

The patient's rehabilitation program was necessarily delayed because of the sacral decubitus ulcer and subsequent surgical procedures, recurrent thrombophlebitis, and intermittent flare-up of the chronic urinary tract infection. Nevertheless, three days after admission he was getting range of motion activity in bed as well as resistance exercise to the upper extremities while lying prone. This bed program continued until November when he was brought up to physical therapy for treatment in the Hubbard tank and ultraviolet irradiation for his decubiti. Exercise for the upper extremities was carried out prone on a litter. In January, 1955, the patient began weight bearing on the tilt table with his legs wrapped in tensor bandages. By February he was allowed to sit in a wheelchair. In April he began standing in the parallel bars and in May he began walking on crutches and long leg braces. In July he no longer used his wheel chair and was climbing stairs. His proficiency in transfer activities was good.

The orthopedics staff was consulted on September 22 and thought weight bearing with a long leg brace on the right leg was permissible.

The plastic surgery staff was consulted and subsequently on October 18 the sacral decubitus ulcer was excised and the defect was closed by a comma flap. A split thickness graft was applied after partial break-down on December 7. The area was treated conservatively with Hubbard tank therapy, mercurochrome and ultraviolet irradiation and was finally healed in May, 1955.

After consultation with the urology staff, straight catheter drainage and intermittent catheter clamping was instituted. By May, 1955, the patient could tolerate catheter clamping for three to four hours. In June the catheter was removed and the patient was emptying his bladder every three to four hours with the aid of a suprapubic pressure. Occasional dribbling incontinence was controlled by ABD pads placed about the genitalia. The patient was given Gantrisin 0.5 gm. four times a day to inhibit flare-ups of the chronic urinary tract infection and Basaljel 30 cc. four times a day to prevent the formation of urinary tract calculi.

Occupational therapy designed to increase strength of the upper extremities was also instituted early.

The patient was often apathetic and lackadaisical in the carrying out of his program. He was depressed from time to time and had to be cajoled and coaxed. His lack of maturity was obviously a factor.

At the time of discharge on October 3, 1955, the patient was completely independent in his activities of daily living. He could manage his personal hygiene needs, transfer in and out of bed, get in and out of car and get up to a standing position from the floor. Ambulation with crutches and long leg braces using a four point gait could be maintained for at least twenty minutes at a time. However, he was afraid to get in and out of a bus unaided or to get up and down curbs. Bowel and bladder control were good. Discharge orders included Gantrisin, Basaljel, and a urinal bag.

The patient was readmitted on October 5. Because of improper use of the urinal bag the venous circulation had been obstructed with resultant edema and abrasions of the genitalia. He was treated with ice packs to the genitalia, ultraviolet irradiation for the abrasions, and antibiotics. This time he was given ABD pads instead of a urinal bag. He was discharged on October 14, 1955, ambulating and independent.

The patient was admitted for the third time on April 10, 1956, for treatment of decubitus ulcers on the right and left thighs. He gave a history of having fallen several times in the ten days before admission. This apparently resulted in injury to the skin beneath the posterior cuff at the proximal end of the long leg braces. The first ulceration was noted approximately ten days prior to admission and subsequently became progressively larger and deeper. He delayed coming to the hospital because he feared he would not be able to continue with his employment.

On examination there was a 9 by 6 centimeter ulcer on the posterolateral aspect of the right thigh which was infected and extended to the fascia. A smaller, more superficial ulcer was present on the posterolateral aspect of the left thigh below the buttock. There was also a small ulcer over the right lateral malleolus.

The ulcers were treated with Neomycin packs, whirlpool and ultra-violet therapy. On April 30, 1956, a secondary closure of the decubitus ulcer on the right thigh was performed. Healing progressed satisfactorily. The patient was discharged on May 18, 1956 and returned to work.

BERNARD SENDLER, M.D.

BEAUTY THAT LASTS FOREVER

The fine white porcelain ware we know as china originated, as the name implies, in the Chinese Empire during the days of the ancient dynasties. In Europe, the secret of making china was discovered anew by the old alchemists, more or less by pure accident, on their eternal search for the way of transmuting common metals into gold. This gave birth to china's other name of "White Gold," a name still used often in trade circles, but more because it so aptly describes the distinctive beauty and value of the prized material.

China's most outstanding attribute is that it does not deteriorate with age. If a modern coffee pot were to be buried in the ground today and left there for our descendants to recover a thousand years from now, it would still look as new as it did on the first day, still be as white, dainty and translucent as ever. Porcelain ware recovered from old merchantmen that have lain at the bottom of the sea for generations and even centuries can be used again for its original purpose after being cleaned of the dirt deposited on it through the years.

Few other materials show such striking qualities. How easily iron begins to rust, how quickly textiles wear out, and how short is the time before wood starts to rot in contrast to china's unlimited durability.

Though so delicate in appearance, porcelain is actually harder than steel. Even the sharpest knife cannot make the slightest trace of a scratch on a piece of hard porcelain baked at a temperature of 2700 degrees.

Furthermore, household china resists the corrosive action of all acids commonly encountered in the home. The juice of a lemon left on a plate or in a cup rinses off without leaving the tiniest stain. Normal earthenware utensils, on the other hand, only too easily become stained if the glaze gets chipped or cracked and no amount of scrubbing and scouring will get rid of the marks.

The history of the material used for chinaware is exciting. The two words "kaolin" and "porcelain" alone embrace a wealth of strange and thrilling happenings. "Ka-o-lin" is Chinese and means a hillside or mountain ridge. On such a ridge several hundred years ago, during the rule of the Sui dynasty, a Chinese shepherd who was tending his flock noticed that a landslide had exposed a layer of whitish clay. He paid no further attention to it until one day he made a fire to keep himself warm in the chill mountain wind and discovered that the heat indelibly baked his footmarks in the soft white mass.

Porcelain derives from the Italian name "porcella" for a fine white seashell and recalls one of the greatest adventures of all time—Marco Polo's journey through the Oriental world. On his return from Mongolia in the year 1295, the daring Venetian traveler introduced to the western world not only the controversial achievement of gunpowder and that less controversial food that was to become an Italian staple, spaghetti, but also the much-admired porcelain and celadon ware of the East. It took more than 400 years before the art of making it became known and practiced in Europe.

In 1702, the grim musketeers of warlike King August of Saxony ordered Johann Friedrich Böttger to find the elusive magic formula for making gold. Instead of solving the haunting mystery of gold making, he became an excellent ceramist. In 1709, after much experimenting, he succeeded in producing a light, exceptionally hard, and translucent-like, material by baking a mixture of kaolin, felspar and quartz. This was the first piece of Dresden china, and to this very day all porcelain is made the same way.

It turned out that Böttger's "new" material was ideal for a whole variety of uses, including of course tableware, and the Saxon monarch soon realized that he had indeed found a way of making gold, although a rather roundabout one. Others were convinced of the fact, too. Madame Pompadour opened a manufactory at Sévres and made a name for the town and good profits for herself. Frederick the Great found a luxurious porcelain service ideally suited to change the Russian Empress's attitude toward Prussia.

Seldom has there been so much fighting, espionage, intrigue, treachery, stealing and suffering on account of any one article as on account of porcelain.

For more than a century, fine chinaware remained reserved for the rich and powerful, until an enterprising young man named Philipp Rosenthal began a two-man business of painting porcelains in a small castle near the German-Czech border; shortly after that he began the manufacture of porcelain. He gradually built a thriving enterprise that distributed its wares over the world,

making the then very rare china available to all. Porcelain bearing the full name of the manufacturer was something new. Philipp Rosenthal was the first to lend his name as a guarantee of the high quality of a particular and distinctive make of china.

ROSENTHAL

DEEP BREATHING IN CORONARY DISEASE

It is a physiological fact that when a person takes a deep chest breath and holds it, negative pressure is produced inside the chest cavity and the pericardium, or heart sac. This fact can be readily demonstrated by testing the chest by the mercury Baumanometer, or blood pressure instrument. Measuring the pericardium or heart sac for negative pressure should be performed only by a specialist. Under normal physiological conditions of the heart sac, the negative pressure as measured by the mercury Baumanometer, records a minus 22 mm of mercury. The two main coronary blood vessels that supply blood to the heart, lie, one on the front surface of the heart, and the other, on the back surface of the heart. How much negative pressure is present inside the coronary blood vessels when the heart sac registers a minus 22 mm of mercury, I do not know. An intriguing experiment for our heart surgeons. But, since these main coronary blood vessels lie on the surface of the heart, it is reasonable to assume that they are also affected by the negative pressure that is present in the heart sac when a deep breath is taken. That the coronary blood vessels are affected by this negative pressure and that it enlarges them, though moderately, I believe, is axiomatic.

When the subject of negative pressure inside the chest, during a deep breath, was studied by our physiology class, a lively discussion with our instructor took place. Many students in our class had had science teaching experience in high school. This time they were students and the physiology professor was the teacher. The professor was patient, cooperative and resourceful. He brought us to a complete understanding of the subject. Had this interesting discussion not taken place, I am sure this physiological fact would have been forgotten by me very shortly. But, some twenty years ago, one of my older brothers passed away suddenly, with a coronary attack. Within another ten years, two more of my brothers died from the same affliction.

The musing on negative pressure inside the heart sac began to take on sober aspect for me, and I began to wonder if there might not be some morsel of help to be gained from this physiological truth of negative pressure inside the heart sac during a deep breath. That the two main coronary blood vessels supplying blood to the heart should expand, at least slightly, under this negative pressure, I felt, should be axiomatic. I checked the physiology textbooks anew. I could find no reference to that effect. Then I checked the medical textbooks for the phenomenon. I reviewed the symposiums on coronary heart disease by specialists conducting these meetings. I did not find any mention of this phase in treating coronary disease—that is, by using deep breathing exercises to aid in expanding the coronary blood vessels. I was not discouraged, but only concluded that the idea had not been considered. Breathing is a normal physiological act, and increasing it to a deep breath, should not add any risk nor danger to the ailing coronary patient. Neither would I classify deep breathing as physical exertion. Any risk involved, I felt, would be purely coincidental.

For over a decade, I have supplemented the treatment of coronary disease with deep breathing exercises. None of the other standard methods of treatment are omitted. As a general practitioner in a rural community, one encounters the average percentage of the various kinds of heart disease. Farmers that are stricken with coronary disease, I encourage to remain on the farm, if possible. I suggest that the patient build a small, but comfortable house to live in, in order that he may continue to enjoy his lifetime environment. Here he will take pleasure in his slowed up tempo of working around the farm at a leisure that he soon learns to live with, and to enjoy. A new environment, irrespective of his ailment, invariably hastens the end.

A coronary patient admitted to the hospital requires at least two to three weeks of rest, combined with the deep breathing exercises and the standard medical treatment. I explain to him what this supplemental, deep breathing exercise is expected to accomplish in conjunction with the standard treatment. I demonstrate for the patient, the manner in which it is performed. Then I have him take over. After he has held his deep breath for possibly eight to ten seconds, he then exhales and inhales three to four times slowly to eliminate the waste material. He then takes a second deep breath

and holds it for eight to ten seconds, followed by three to four breaths to air out the lungs. These deep breathing exercises are repeated in this manner until he has performed them eight to ten times. I suggest that he performs them in a lesiurely manner, in order to prevent over-ventilation of the lungs. I have not observed that these exercises have strained the heart nor patient. I suggest that the patient start these deep breathing exercises as soon as he awakens in the morning, with the last exercise being performed when he retires at night. During the daytime, I advise him to perform them at least ten times at regular intervals. By the time that the patient is dismissed from the hospital the exercise has become routine with him. Some have reported that these exercises are relaxing. Before the patient returns home, he is advised to continue the breathing exercises routinely. Should he, at any time, experience any discomfort in the chest, he is to take a deep breath immediately. Plus this, he is, of course, to use the heart medicine prescribed.

Some six years ago, I removed the gall bladder from an ailing coronary patient, whom I had, for several years, taken care of for his heart condition. It was interesting to learn from him how the deep breathing exercises had helped him to differentiate the gall bladder distress from the heart distress. If it was heart distress, he was relieved by the deep breathing exercises. If it was gall bladder distress, he was not relieved. He was quite insistent upon having the gall bladder removed, in spite of the coronary risk. He made an uneventful surgical recovery.

Last fall, this same retired farmer, living on his farm, in the small, attractive home he had built for himself and his wife, a quarter of a mile from his former home that his son and family now occupy, told me the following story. He was operating the tractor and his son was on the corn picker. The father was seized with a heart attack. He took a deep breath, at the same time he flicked off the ignition key, thus stopping the motor. Being aware of his Dad's heart condition, the son came over to see what was wrong. The father carried out his deep breathing exercise, and after a few deep breaths, he became pain free. He retired from the field for the remainder of the day, but after a couple days of rest, he returned to the tractor, and remained on the job until the corn picking was completed, without any further trouble.

He concluded the story by adding, "It's the most convenient medicine I could possibly carry around with me."

Clinically, as I observe these patients, I am favorably impressed with their progress. I believe that the supplementary deep breathing exercise added to the standard treatment of coronary disease, is very encouraging. Two forces acting in unison to enlarge the lumen of the coronary blood vessels to increase the blood and oxygen supply to the heart muscle, I believe, accounts for this clinical improvement.

As one muses on this phase of coronary disease, one immediately begins to wonder what deep breathing exercises, if practiced daily, might do to prevent coronary disaster. Preventative medicine. The pace of the race is constantly growing more furious, and coronary disease flourishes in the increased tempo. Possibly, adding these exercises to our busy schedule in order to supply more blood and oxygen to the heart, might pay a liberal dividend.

Shakespeare has left us a quotation well worth musing on:

"Our remedies oft in ourselves do lie, which we ascribe to heaven."

President's Letter

SUDDENLY YOU ARE A GOVERNMENT EMPLOYE

Physicians in Britain were busy tending to the health needs of a nation recovering from the full economic, physical and social impact of World War II.

The day to day activities of the British physicians overshadowed the July 5, 1948, date when the National Health Service Act of 1946 went into effect in England, Scotland and Wales.

Many believed that this was needed to bolster inadequate private health care. Suddenly British physicians found that they were salaried employes of the state. These physicians are now busier than ever before. We are told that the maximum number of patients which a British physician can carry on his panel is 3,500. For his service he receives an average of $2.73 per patient per year. It has been estimated that a doctor must see more than one hundred patients each day in order to maintain an average net income of $4,000 a year.

Few general practitioners are allowed the use of British hospitals. These are reserved for the medical specialist, also a government salaried employe.

By contrast, a Health Insurance Foundation survey indicates that the average American family doctor treats about twenty-six patients a day and spends about eight hours each day on house and hospital calls. The survey also showed that at least three-quarters of the physicians interviewed were in private practice. In contrast to the British National Health Service system, the survey showed that seven out of eight American doctors were affiliated with one or more hospitals.

It has been said that as a nation's health goes, so goes the nation. America is the healthiest nation in the world and will continue to set the pace in this respect only as long as the freedom of medical practice is maintained.

Like Britain, government controlled medicine has replaced freedom of medical practice in Germany, France and the trend is growing. In Canada, busy physicians and private insurance companies were shocked with the suddenness of the enactment of a government controlled hospital care program. Canadian observers state that political steam roller tactics were successful in part because busy physicians failed to acquaint themselves with the facts. Passage of the Forand Bill could effect similar results in the United States.

The House Ways and Means Committee Hearings on the Forand Bill concluded July 17. Those who favored passage of legislation which would eventually provide compulsory government health care for all Americans, took time to present their case. The American Medical Association, along with other agencies and organizations opposing the Forand Bill, pointed out to legislators why Americans do not need the Forand type of legislation.

Unless we as individual physicians and county medical societies can do a first class job of urging legislators that medicine and politics do not mix, suddenly we may discover that we, too, are employes in a government controlled health service.

Sincerely yours,

Benjamin B. Foulston M.D.

EMPLOYE MEDICAL PROGRAMS SHOW MARKED INCREASE

Company medical programs for employes have been greatly broadened since the turn of the century, and many American firms now are taking active steps not only to treat job-connected injuries and diseases but to prevent them, the National Industrial Conference Board reports in a recently released study by that organization.

In many cases, the Conference Board finds, this prevention program extends also to nonoccupational ailments through health maintenance measures which provide periodic physical examinations of employes.

Co-operators in the study list many reasons for their desire to keep the worker occupationally fit at all times. Among them is the fact that competition for efficient personnel has impressed upon managements the importance of safeguarding the health of their employes, in whom they have invested time and money.

The physical well-being of employes is not the only occupational health problem of concern among many of these companies. The NICB study finds that increasing attention is being focused by some firms on the control of mental disease among their employes.

U. S. and Canadian Firms Studied

Thirty-six Canadian companies and 242 United States firms provided information for the Conference Board study. In addition, a number of concerns permitted the NICB to study their medical departments and services through field trips.

The employe health and medical programs maintained by these companies cover a wide range. More than four-fifths of the United States companies and almost nine-tenths of the Canadian group require preplacement physical examinations of every prospective employe including those on the executive level. Periodic physical examinations also are becoming an increasingly common practice among companies. Better than four-fifths of the co-operators give periodic examinations either to all or to selected groups of employes.

Physical examinations following temporary layoffs are required by three-fifths of all U. S. co-operating companies and by more than two-fifths of the Canadian respondents. An examination at the termination of employment, however, is a less frequent practice. About 15 per cent of the U. S. co-operators and only three of the responding Canadian firms have such examinations.

Few Dentists on Payrolls

Only a handful of the co-operating American companies, and none of the Canadian firms, employ dentists full or part time, according to The Conference Board. Many respondents believe that an in-plant dental program is an additional and unnecessary expense.

More than three-fourths of the U. S. co-operating firms and two-thirds of the Canadian respondents have eye protection programs of some kind. These include not only testing of employes, but, in many cases, an evaluation of each job and work area in a company to determine the hazards involved, the degree of eyesight required, and the kind of eye protection needed.

Care of Hearing is Expanding

While auditory examinations and measures to provide ear protection are not as common as eye protection programs, industry in recent years has become increasingly conscious of compensation risks entailed in excessive noise, the NICB finds. As a result, many companies have instituted programs which include efforts to reduce noise in the plant and auditory tests during an employe's working life to determine how much hearing loss is the result of work surroundings and how much is due to his own physical deterioration. About a fourth of the U. S. co-operating companies have some kind of ear protection plan and about 11 per cent more plan to have them. Slightly under one-fourth of the Canadian firms either have, or plan to have, such services.

Mental hygiene is considered important in many companies, although only ten of all responding firms employ psychiatrists. The medical personnel in a large percentage of all co-operating companies offer a type of counseling service designed to help the employe lead a better adjusted life. They counsel employes on how to care for themselves—how to eat, rest, relax, avoid accidents, get

along with associates—and how to live with or remedy any physical impairments.

Since the job environment is closely associated with the health of workers, attention to atmospheric conditions, working materials and processes, and physical equipment and surroundings is of concern to medical personnel. Among 199 United States and Canadian co-operating firms that have industrial hygiene programs, about 73 per cent make the medical department responsible for them.

Scope of a Program

Many factors influence the scope of activity of the medical departments maintained by co-operating companies, the NICB study finds. These include the size of the firm, the type of business it is engaged in, and the attitude of top management toward the need for a comprehensive program requiring the investment of substantial funds.

A more subtle influence, but one that finally determines the extent of medical operations in many companies, is the differing philosophy of doctors, and very often of company managements, as to what a preventive health program can include without putting the company in the position of practicing medicine.

MAJOR CLOSED PANEL HEALTH CARE PLANS MERGED

Two organizations representing fifty major closed panel health care plans have joined forces. Merger of the American Labor Health Association and the Group Health Federation of America to form the Group Health Association of America was announced May 26.

How this powerful "straw in the wind" can affect the future course of "free choice" cannot be immediately determined. However, physicians are advised to keep abreast of the progress of the combined forces represented by Group Health Association of America.

Publications of the combined groups assert that the merger represents the most important event in the organization of medical care for the consumer since the advent of modern medical science. Members are being told that the new organization will speak in the interests of all consumers of medical care—labor union members, city people and farmers, as well as subscribers to group health plans.

GHAA will not only protect consumers' right to organize group health plans to prepay their health costs, leaders declared, but will uphold the right of physicians to work with these plans.

According to Jerry Voorhis, Executive Secretary, this historic meeting "marks a most important milestone in the progress of the earnest, wise and devoted people who have given so generously of their time, talent, and money to the group health movement during the past two decades. Perhaps ours is an idea whose hour has indeed come. At least we should proceed in faith that that is so."

A four-point legislative program was adopted by the new organization. The program would: Vigorously support the Humphrey Bill, S. 2009, to provide long-term interest bearing loans for the building and equipping of health centers financed by prepaid loans. Horace R. Hansen, GHAA's general counsel, reported that a cursory survey of a limited number of prepaid plans disclosed they could use $37 million for building and $7 million for equipment; Endorse an amendment to the tax laws to give nonprofit health plans operating health facilities a tax classification to make them eligible to receive gifts which would be tax deductible for the donors; Endorse the principle of the Forand Bill—the use of the Social Security mechanism to pay for health care for the aged; Endorse the principle of health insurance to Federal civilian employees, including the right of the employees to choose coverage by prepaid comprehensive health plans.

Call to Action

GHAA legal counsel, Horace R. Hansen, St. Paul, outlined the following vigorous program designed to remove the barriers to closed panel plans. He recommended that the group: Support lawsuits brought by individual plans against "vicious medical boycotts in operation against lay plans." Mr. Hansen claimed that "in every lawsuit in the last twenty years involving boycott, the plan has prevailed over the (medical) society." "Acquaint hospital boards and the many religious organizations, which endow them, with the purposes of our plans and the selfish designs of the local medical society in drawing hospitals into disciplinary action against our doctors."

Also proposed by Mr. Hansen was a state "hospital nondiscrimination bill." Such legislation would provide that "a hospital may not discriminate against a doctor seeking privileges, solely because of his association with the plan, while reserv-

ing any other legitimate reasons for denying privileges."

Organized "watch dog" committees in each state in advance of legislative session to combat bills restricting closed panel plans and to urge repeal of such laws now in force in twenty-six states.

To support these committees, Mr. Hansen said, "We should start actions testing such provisions in some states having restrictive legislation, on grounds that giving organized medicine a virtual monopoly in operating a prepayment plan is unconstitutional, as being vague, as being class legislation, and as unlawfully delegating administrative authority."

Mr. Hansen also urged that the states set up mechanisms in addition to licensures for policing the quality of medical care. He also recommended that two lay persons be included on each State Board of Medical Examiners in order "to provide a window into the conduct of medical practice."

GHFA Founded in Minnesota

Group Health Federation of America was organized thirteen years ago at Two Harbors, Minnesota, as Cooperative Health Federation of America. In 1957, again at Two Harbors, the name was changed to Group Health Federation.

American Labor Health Association was formed seven years ago, as the Association of Labor Health Administrators with a membership made up of individuals. Again the combined publications of the groups point out that for many years the two like-minded organizations worked side-by-side with the same purpose—to spread their mutual belief that better medical care for the American people can come about through consumer-sponsored, comprehensive prepaid, group practice plans.

They state that "Group Health" was retained in the title of the new organization because it has a definite meaning in law and in the organization of medical care as well as in the minds of the people.

ACCORDING TO CITATION . . .

Exclusion of Osteopaths from Staff of County Hospital Upheld

The Court of Civil Appeals of Texas has held that osteopaths can be excluded from the staff of a county hospital because they hold only degrees of doctor of osteopathy.

At the same time, the Court stated that the rule of the Board of Trustees of the hospital requiring county hospital members to be graduates of Schools of Medicine approved by the American Medical Association, while reasonable, was invalid "because it constitutes a delegation of power by the Board to itself to determine the qualifications of its staff members. There is nothing, in our opinion, which will prevent the Board from adopting the same standards as are required at a given time by the American Medical Association."

The Art of Medicine

PR

Carl H. Woyke, B.A.
Editor

DOCTORS' FEES PRO AND CON

Whenever doctors' fees are discussed, the art of medicine of every member of the medical profession is immediately involved.

Recently George E. Sokolsky, a King Feature Syndicate editorialist, wrote one article on doctors' fees. The original article prompted a large mail response from the readers of Mr. Sokolsky's column. A second article was devoted to presenting the pros and cons of doctors' fees as reflected in the letters which the columnist received.

In his second article, Mr. Sokolsky commented:

"I have received a rather large mail in response to an article I wrote about doctors' fees. Those who complain have several arguments which ought to be aired. On the subject that doctors' fees are exorbitant, I can hardly agree with the critics. A man is entitled to charge what he thinks his services are worth. If an hourly wage worker wants more money for his work, he might go on strike to get it. School teachers and other city employes threaten to go on strike for more money.

Called Scalper

"But if a doctor charges what he thinks his services are worth, he is called a scalper. A reader writes: '. . . Too many doctors today are absolutely commercial. They are thinking more of the almighty dollar than of the patient. . . .'

"A doctor can think about his patients all day long, but he still has to pay for taxes, rent, food and clothing, books, publications and instruments.

"He has no way of earning a living except by charging for his time, skill and services.

"Some physicians and surgeons may charge more than their patients want to pay. This is a private transaction involving two individuals who can usually reach an understanding in advance of the services being rendered.

"The complaint is made that doctors are hard to find on Wednesday afternoons and Sundays.

"This is one of the most difficult problems to solve. Folks get sick every day and at all hours of the day, but it is inhuman to expect that a doctor or anyone else will be around twenty-four hours a day, 365 days a year.

"He might like to go fishing, too. He might like to visit his mother or attend a convention. He might even want to go to a show with his wife or to go courting so he can get a wife.

Larger Cities

"In the larger cities, arrangements are usually made by doctors to cover for their colleagues through a telephone answering service.

"It does not always work out satisfactorily, particularly in a real emergency. Local medical associations ought to work out these problems satisfactorily.

"It would be both an opportunity and an experience for young interns to service such an emergency committee directly under a medical association so that doctors could be free on Sunday and Wednesday afternoons which some take off as a break.

"The doctor who refuses under any circumstances to go on a house visit is wrong. I have never encountered such a physician, not even a specialist, but if there are such, they should be pilloried. There can be no reason for an absolute refusal to make a house call.

"The criticism that doctors insist that patients go to a hospital for treatment is stupid.

"That is the best place to go to. It is impossible to give a patient as competent a treatment as in a hospital.

Shortage

"When a doctor instructs a patient to go to a hospital, that is where the patient should go. It is unfortunate that there is a shortage of hospitals in this country and it is a crime that some of the hospital workers in our large cities are being organized by professional union operators.

"Of course, everybody who works in a hospital is underpaid but it also is true that practically no hospital is in the black.

"The suggestion that comes from one reader that 'doctors use all of the facilities of hospitals as places of business, putting it bluntly, without paying a cent for the privilege' strikes me as particularly nonsensical.

"Any hospital-connected physician, having a private practice, works for that hospital for free. If hospitals had to pay doctors for all the work they do in the hospital, institutions would have to close down after the first year's budget.

Conclusion

"After reading quite a large number of letters, I have reached the conclusion that many persons expect to get medical services for nothing; that they do not appreciate that a physician is a human being with the usual habits, ailments and requirements of other human beings; that many Americans have lost the habit of paying-as-you-go but have, because of the depression and the wars, taken on a habit of having things done for them; that they do not appreciate top value but will accept what comes so long as it costs nothing."

ARE DOCTOR PUBLIC RELATIONS IN TRANSITION?

"Have the people of America really changed their attitude toward their doctor?" inquires an editorial in the *Westchester Medical Bulletin.*

"The doctor of a few generations ago certainly was a revered and respected person. Judging from the tone of many magazine and newspaper articles, this is no longer true. It seems that anti-doctor literature is very popular with the press and that people really want to read it. Lambasting doctors and their attitudes and their fees has become a frequent pastime of some metropolitan newspaper writers. When circulation slumps a series of articles criticizing organized medicine would appear to be a good remedy. This is apparently true with the popular magazines, also.

"Is this done because the readers wish to see their physicians placed in such poor perspective? The best that we seem to be able to do in the press is to make occasional, feeble and belated denials of charges that are untrue. If the press does express the attitude of the people, then physicians everywhere should do some serious self-examination.

"Certainly the failure to maintain esteem does not arise from the lack of excellence of medical care. This is, today, better than it has ever been, and patients know it. The dissatisfaction, then, must lie elsewhere, and perhaps we have not far to look to find it.

"In recent years the development and extensive use of specific drugs have shortened, simplified, and in some cases, eliminated diagnosis. The greater employment of laboratories and diagnostic machines has gone a long way toward seeming to eliminate the doctor. The use of machines and drugs is not a reversible process, nor would we want it to be. However, it does result in some feeling by the patient that it is not entirely the doctor who is helping him.

"Overspecialization has also aroused the irritation of the public. 'Nowadays,' the patient complains, 'I have to sit down and figure out for myself whether I need a chest man, a bone man, a heart man, a stomach man or some kind of man I've never even heard of, and then when I do decide, I don't know where to find him.' So he settles for going to a clinic where he is certainly not treated as an individual but feels at some point in the series of doctors he sees he'll encounter the one who goes with his ailment.

"There are no ready answers to the problem but it seems clear that we, the doctors, should make an extra effort to show interest in the patient as an individual and let him know that mechanization and specialization has not basically changed us. In addition, a well planned constructive public presentation of the doctor's case should be made."

"DOCTOR, TELL ME" IS ON VACATION

The current "Doctor, Tell Me" series has ended. The final program, "Vacations" was scheduled to be heard on the twenty-five participating Minnesota radio stations during the week of July 26. The series will resume its regular schedule during the week of October 26.

Meanwhile, regional county medical societies and individual members can perform an important public relations gesture by extending personal and written appreciation to radio stations in their immediate areas which have scheduled "Doctor, Tell Me" in 1958-59.

Radio stations which participated in the recently conducted series included:

KATE—Albert Lea; KXRA—Alexandria; KBMO—Benson; KLIZ—Brainerd; KROX—Crookston; KDLM—Detroit Lakes; KDAL—Duluth; WELY—Ely; WEVE—Eveleth; KSUM—Fairmont; KDHL—Faribault; KOZY—Grand Rapids; KLFD—Litchfield; KYSM—Mankato; KMHL—Marshall; KNUJ—New Ulm; WCMP—Pine City; KLOH—Pipestone; KLGR—Redwood Falls; KFAM—St. Cloud; KTRF—Thief River Falls; KUOM—Twin Cities; KWAD—Wadena; KWLM—Willmar; KWNO—Winona; KWOA—Worthington.

Your state office is interested in receiving your program ideas for the coming year. If the radio station in your immediate area has not previously scheduled "Doctor, Tell Me," a personal chat by you or another member of your county society with the program director might provide the necessary encouragement.

Please forward to this office the names of additional radio stations which have expressed interest in the "Doctor, Tell Me" series. Further details regarding tapes and schedules will be provided.

Public Health

IT'S A LAW

Register Ionizing Radiation Sources

Regulations of the Minnesota State Board of Health adopted in December, 1958, require the registration of all sources of ionizing radiation with the Minnesota Department of Health on special forms provided by the Department biennially in odd numbered years. The regulations provided for an initial registration during the month of March, 1959.

During February of this year, the forms for this registration procedure were sent to more than 1,300 physicians in Minnesota. As of July 1, approximately 500 physicians had registered their ionizing radiation sources, including x-ray equipment, with the Department. There is good reason to believe that a great many x-ray machines have not yet been registered. All physicians in Minnesota, therefore, who have x-ray equipment and have not registered them, are strongly urged to do so. If registration forms were not received, or if they have been mislaid, additional forms are available from the Division of Environmental Sanitation, Minnesota Department of Health, University Campus, Minneapolis 14, Minnesota.

REPORT POLIO CASES IMMEDIATELY

Physicians are requested to report promptly all cases of *paralytic poliomyelitis* by telephone to the Minnesota Department of Health, FEderal 9-7751, University Campus, Minneapolis. The department wishes to know especially (1) the type and extent of disease present; (2) the vaccination status: number of doses, and dates of inoculations; (3) name, age, address, date of onset of symptoms of the patient.

For the laboratory confirmation of the diagnosis, one or two stool specimens from the patient are most useful and should be submitted routinely and early; virus isolation containers should be used. If ordinary stool bacterial culture outfits are used, the special preservative should be dumped out and the data card marked "For Polio Virus."

Paired blood specimens, the first collected immediately after onset of the disease, the second two to four weeks later, are required.

QUARANTINE COVERAGE OF ST. LAWRENCE SEAWAY TRAFFIC

The Public Health Service Division of Foreign Quarantine and its Canadian counterpart, in considering the health problems associated with the St. Lawrence Seaway traffic, find that inspection of this traffic can best be done before shipping is allowed to enter the Seaway. Accordingly, Division of Foreign Quarantine is detailing a staff of four quarantine inspectors to Montreal to cover this work co-operatively with the Canadian health administration. This detail is headed by Quarantine Inspector William F. Reider, and will be responsible to Medical Director Alonzo Brand, Medical Officer in Charge, U. S. Public Health Service, American Consulate General, Toronto, Canada, who will maintain necessary liaison with Dr. W. H. Frost, Chief, Quarantine, Immigration Medical and Sick Mariners Service, Department of National Health and Welfare, Ottawa, Canada. The address of this detail is: United States Public Health Service, Seaway Quarantine Operation, 320 Baldwin Street, Montreal 5, P. Q., Canada.

The following functions will be performed:

1. Persons will be given physical inspection, including review of their immunization records, on arrival from foreign countries (except arrival direct from Canada, the Islands of St. Pierre and Miquelon, Iceland, Greenland, the West Coast of Lower California, Cuba, the Bahama Islands, the Canal Zone, the Bermuda Islands, the British Virgin Islands, or the Islands of Aruba and Curacao), and control measures will be applied according to Public Health Service Foreign Quarantine Regulations. Persons with any evidence of serious communicable disease will be referred to Canadian health officials for appropriate action before the vessel is cleared.

2. Arriving aliens will be inspected pursuant to immigration-medical requirements, with special attention to immigrants and alien seamen. Findings will be reported to the Immigration and Naturalization Service.

3. Sanitary inspection of vessels will be performed, including inspection for presence of rodents and other disease vectors. The intensity and type of inspection will vary as the need indicates. Findings on American flag vessels, other than rodent infestation, will be reported to the Public Health Service Regional Medical Director for action. Necessary action on foreign flag vessels will be taken by Division of Foreign Quarantine. Responsibility for rodent control on all ships arriving from foreign ports rests with Division of Foreign Quarantine.

4. Other "things" aboard the ship will be inspected for compliance with import requirements. These items, covered in Subpart J of Public Health Service Regulations, include lather brushes, dogs, cats, monkeys, psittacine birds, shipments of disease organisms and vectors, and dead bodies.

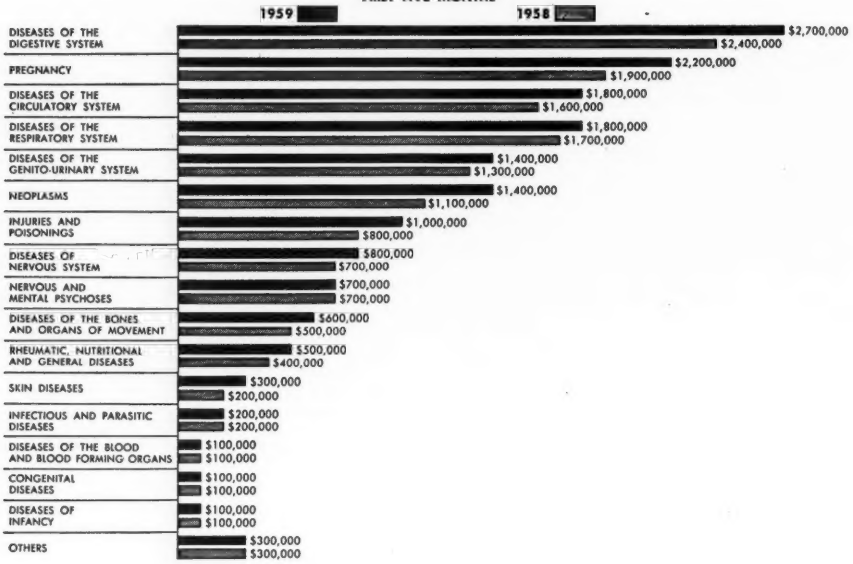
Ships not bearing a valid deratting or deratting exemption certificate (pursuant to International Sanitary Regulations) will be given special inspection, and will be deratted or given the exemption certificate as the findings indicate.

Questions or problems in connection with the program should be addressed to Andrew P. Sackett, Medical Director, Chief, Division of Foreign Quarantine Bureau of Medical Services, Department of Health Education and Welfare, Washington 25, D. C.

Minnesota Blue Shield-Blue Cross

The Blue Shield statistical report for the first four months of this year reveals continued increases in utilization of contracts by participant subscribers. 128,992 doctors' services were provided benefits by the Plan during the months of January through April, 1959. This figure represents an increase of 11,742 services over the number paid by Blue Shield in the same period of 1958.

Payments to physicians also increased in the first four months of 1959 over the same months of last year. As of April 30, 1959, Blue Shield had paid $3,463,726 for subscriber care while $3,248,614 was paid to doctors for services to subscribers as of the same date in 1958. Thus, Blue Shield paid $215,112 more to physicians during the first four months of 1959 than was paid by the Plan in the same months of last year.



A breakdown of Blue Shield payments according to Plan A and Plan B shows that most of the increase in 1959 over 1958 is accounted for in Plan B benefits. Plan B payments in the first four months of 1959 were $595,039 as compared to $437,003 last year. Plan A benefits amounted to $2,868,686 January through April of this year and $2,811,610 during the same period of 1958.

Blue Cross payments to hospitals during the first five months of 1959 for care incurred by subscribers and dependents totaled $16,017,300, an increase of $1,876,489 or 11.7 per cent over Blue Cross hospitalization expense incurred during the same period of the previous year. Approximately one-half of this increase in Blue Cross payments to hospitals occurs in the hospital care costs incurred by Blue Cross patients hospitalized because of diseases of the digestive system, pregnancy, diseases of the circulatory and respiratory systems.

Blue Cross membership growth, the transfer of subscribers to higher levels of benefits and the increased subscriber usage of Blue Cross benefits are not the only contributing factors to this significant increase in Blue Cross hospitalization expense.

Progress being constantly achieved in hospital facilities, increased subscriber usage of these facilities, improvements in the field of modern medicine and increased cost of hospital operation are continuing to play a major role in the continued spiral of Blue Cross costs.

New wide-use dosage form

of the outstanding

anticholinergic-antispasmodic

PRO-BANTHĪNE®

TABLETS

(HALF STRENGTH)

Pro-Banthīne (Half Strength) has been especially designed for your prescribing convenience.

This new form provides flexibility of dosage from low levels of one tablet t.i.d. for patients with minimal distress, to one or two tablets every 2 or 3 hours for those with more pronounced symptoms.

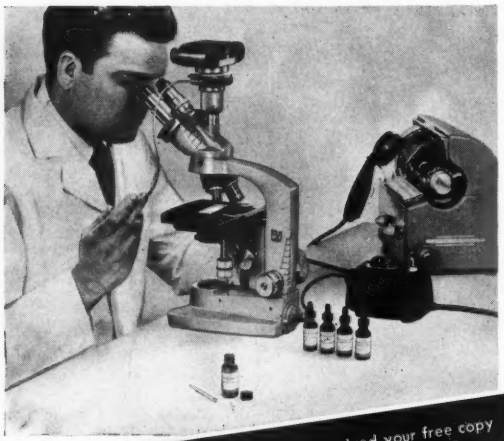
Primary indications are gastrointestinal spasm, bladder spasm, maintenance therapy of peptic ulcer and "irritable bowel" syndrome. The lower dosage also has a field of usefulness in smooth muscle spasm of children and geriatric patients.

when your prescription reads—

℞ Pro-Banthīne Tablets (Half Strength)

—the pharmacist will dispense this new size (7½ mg.)

PRO-BANTHĪNE *(brand of propantheline bromide)*



Dosage forms:

Pro-Banthīne tablets (15 mg.)
Pro-Banthīne tablets (Half Strength) (7½ mg.)
Pro-Banthīne ampuls (30 mg.)

ULMER

LABORATORY REAGENTS and stains

New CATALOG

If you haven't already received your free copy of our new 64 page catalog of clinical Reagents and Stains, write for same today. It lists all of the more commonly used laboratory reagents and stains. You will find it very helpful.

ULMER REAGENTS AND STAINS HELP ACHIEVE ACCURACY

It is our objective to produce the finest reagents obtainable for clinical laboratory use. Their consistent accuracy saves hours of the technician's time.

Our scientific laboratory control is your assurance that Ulmer reagents are always fresh and meet the most exacting standards for each procedure. Every step of the manufacturing process is checked from the raw materials to the finished product. Moreover, our chemists are available to assist with any procedures with which you may be experiencing difficulties. Do not hesitate to call on them for assistance or advice.

For prompt and efficient service as well as guaranteed satisfaction, insist on Ulmer Reagents and order them direct from P & H.

Communications

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

HEART GRANTS

Sixty heart research grants totaling $216,750 were awarded at the twelfth annual meeting of the Minnesota Heart Association held in Minneapolis, in July.

The grants, allocated from the 1959 Heart Fund drive, will be spent in laboratories at eight Minnesota institutions, and will finance studies into all forms of heart and circulatory diseases.

Most of the grants went to University of Minnesota researchers (46). Others went to scientists at Mayo Clinic, Rochester; Hormel Institute, Austin; Minneapolis General Hospital; Mt. Sinai, Hospital, Minneapolis; St. Barnabas Hospital, Minneapolis; St. Joseph's Hospital, St. Paul; and St. Mary's Hospital, Duluth.

Three awards were fellowships to outstanding young scientists who will work and train under experienced researchers. Two others were to Established Investigators who are receiving long term support from the Minnesota Heart Association.

In addition, the Association voted to double its summer fellowships program for high school and college students, and allocated $10,000 for this purpose in 1960. The program will continue in its third consecutive year at the Mayo Clinic and University of Minnesota.

Total income from the 1959 Heart Fund drive was reported at $597,573, representing 115 per cent of the state goal.

MINNESOTA HEART ASSOCIATION

IS THERE A RHEUMATIC CONSTITUTION?

The low incidence of rheumatic fever among the many individuals infected with streptococcal disease, even when untreated, has led to the suggestion that it is not the germ, nor the infection, but rather the constitution of the victim that is crucial in the pathologic constellation of rheumatic fever. A study of physical appearance, body build, blood groups, and saliva tests in active and inactive cases of rheumatic fever showed no significant statistical difference from that in the general population. The one positive constitutional feature brought out in this study is hyperextensibility of the joints.—EUGENE F. DIAMOND, M.D., *Journal of Pediatrics,* March, 1959.

In Memoriam

CONRAD M. DOVRE

Dr. Conrad M. Dovre, retired St. Paul physician, died June 22, 1959, at his home at 1787 James, St. Paul. He was seventy-four years old at the time of his death.

Dr. Dovre was born in Oslo, Norway, and came to the United States in 1905. He was a graduate of Marquette University Medical School in Milwaukee, Wisconsin, and interned for one and a half years at St. Joseph's Hospital in St. Paul.

Dr. Dovre began his practice in 1913 at Rice and University in St. Paul and later moved to the Hamm Building. He practiced there until the time of his retirement in 1953. He was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the Ancient Landmark Number Five, Masonic Lodge.

Survivors are his wife, Esther, and two sisters in Norway.

CONRAD A. NEUMANN

Dr. Conrad A. Neumann, Holler Hill, Winona, died July 6, 1959. Dr. Neumann was seventy-seven years old at the time of his death. His preliminary education was obtained in the Winona High School and later he attended the University of Minnesota.

He received his medical degree from Northwestern University School of Medicine. Following his internship in the Milwaukee County Hospital, he returned to Lewiston in 1909 and practiced there until 1927. He established residence in Winona in 1928 when he joined the staff of the Winona Clinic. In 1948, he retired from the Winona Clinic, moved to Holler Hill, Winona, and resumed his practice in Lewiston.

He was a member of the Winona County Medical Society, Minnesota State Medical Association and the American Medical Association.

Dr. Neumann was named a member of the Fifty-year Club of the Minnesota State Medical Association in 1959.

Survivors are his brother, John H. Neumann, Lewiston; two sisters, Lydia, Downers Grove, Illinois, and Anna, Seattle, Washington; and two daughters, Mrs. Milan A. Johnston, Minneapolis; and Mrs. John S. Lucas, Winona.

ON SUDDEN OR RAPID WHITENING OF THE HAIR

A case is cited of a man who experienced complete whitening of the hair of the head in not more than six weeks after an accident. Seventeen months after this accident, the author had a chance to re-examine the patient, who had just returned from a trip to Florida and looked sunburned. The patient was worried about the sudden appearance of white spots—vitiligo—on different parts of his body. On re-examination, the author was convinced that the original sudden whitening of the hair in this case, and in many of the previously reported ones, belongs in the group of vitiligos.—ALFRED J. EPHRAIM, M.D., *AMA Archives of Dermatology,* February, 1959.

Meetings and Announcements

STATE

Northern Minnesota Medical Association, annual meeting, Duluth, Minnesota, Friday and Saturday, September 11 and 12.

NATIONAL

Academy of Psychosomatic Medicine, Sixth Annual Meeting, October 15-17, 1959 at the Sheraton-Cleveland Hotel, Cleveland, Ohio. For further information contact Dr. Bertram B. Moss, Suite 1035, 55 East Washington Street, Chicago 2, Illinois.

American College of Surgeons, Annual Clinical Congress, Atlantic City, New Jersey, September 28-October 2. Dr. Michael L. Mason, Secretary, 40 East Erie Street, Chicago 11, Illinois.

American Heart Association, Annual Meeting and Scientific Sessions, October 23-27, 1959, Philadelphia. Scientific Sessions scheduled for October 23-25 at Trade and Convention Center. Annual Meeting of the National Assembly, Hotel Bellevue Stratford, October 26-27. Information available from Minnesota Heart Association, 1821 University Avenue, St. Paul 4, Minnesota.

The annual course in Postgraduate Gastroenterology, sponsored by The American College of Gastroenterology, will be given at The Biltmore in Los Angeles, California, September 24, 25 and 26, 1959. For further information and enrollment, write to the American College of Gastroenterology, 33 West 60th Street, New York 23, New York.

The Academy of Psychosomatic Medicine has announced its Sixth Annual Meeting, October 15-17, 1959, at the Sheraton-Cleveland Hotel in Cleveland. For further information, write to Dr. Bertram B. Moss, Suite 1035, 55 East Washington Street, Chicago 2, Illinois.

The American Rhinologic Society will hold its fifth annual meeting in the Belmont Hotel, Chicago, October 10. The meeting will be preceded by a surgical seminar in the Illinois Masonic Hospital, Chicago, October 7-9. For further information write to Dr. Robert M. Hansen, Secretary, 1735 No. Wheeler Avenue, Portland 12, Oregon.

The American Institute of Ultrasonics in Medicine will hold their Annual Meeting on September 2, 1959, at the Leamington Hotel, Minneapolis, Minn. For any further information contact John H. Aldes, M.D., Secretary, 4833 Fountain Avenue, Los Angeles 29, California.

Interstate Postgraduate Medical Association, Forty-fourth Scientific Assembly, Palmer House, Chicago, Illinois, November 2-5, 1959.

Institute of Industrial Medicine of New York University Post-Graduate Medical School, two-month course for physicians in Occupational Medicine. Presentations include Preventive Medicine, Administrative Medicine, Occupational Diseases, and Industrial Hygiene. The course will be a full-time, two-month course, September 14 through November 6, 1959, tuition—$375, field trip expense—$25. For applications, address Office of the Associate Dean, New York University Post-Graduate Medical School, 550 First Avenue, New York 16, New York.

Mississippi Valley Medical Society, Twenty-fourth Annual Meeting, Chase Hotel, St. Louis, Missouri, September 29-October 1. Complete programs available from Dr. Harold Swanberg, M.D., Secretary, W. C. U. Building, Quincy, Illinois.

National Society for Crippled Children and Adults, Annual Convention, November 29-December 2, 1959, Palmer House, Chicago. For further information, write Miss Catharine Bauer, Director of Information, 2023 West Ogden Avenue, Chicago 12, Illinois.

The Twenty-fourth Annal Congress of the North American Federation, International College of Surgeons, will be held in the Palmer House, Chicago, September 13-17. Surgeons desiring to present papers should write to Dr. Peter A. Rosi, International College of Surgeons, 1516 Lake Shore Drive, Chicago 10.

Pan-Pacific Surgical Association, Eighth Congress, Honolulu, Hawaii, September 28 through October 5 in 1960. Further information and brochures may be obtained by writing to Dr. F. J. Pinkerton, Director General of the Pan-Pacific Surgical Association, Suite 230, Alexander Young Building, Honolulu 13, Hawaii.

A Postgraduate Course in Occupational Skin Problems will be given at the Institute of Industrial Health to be held at the University of Cincinnati, Cincinnati, Ohio, October 26-30, 1959. For further information, write to the Secretary, Institute of Industrial Health, The Kettering Laboratory, Eden and Bethesda Avenues, Cincinnati 19, Ohio.

Twelfth Annual Meeting of the American Association of Blood Banks, Edgewater Beach Hotel, Chicago, Illinois, November 4-7, 1959. For further information write, Office of the Secretary, American Association of Blood Banks, 30 North Michigan Avenue, Chicago 2, Illinois.

Twelfth Annual Conference on Electrical Techniques in Medicine and Biology, Sheraton Hotel, Philadelphia, Pennsylvania, November 10-12, 1959. For further information, write Dr. Herman P. Schwan, Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, Pennsylvania.

Eighty-seventh Annual Meeting of the American Public Health Association, Atlantic City Convention Hall, Atlantic City, New Jersey, October 19-23, 1959.

INTERNATIONAL

Eighth Bahamas Medical Conference, British Colonial Hotel, Nassau, Bahamas, November 27 until December 17, 1959.

UNIVERSITY OF NEBRASKA, POSTGRADUATE COURSE

The University of Nebraska College of Medicine will offer the first of a ten-course series of postgraduate programs September 28-30. Dr. Enrique Cabrera, Institute of Cardiology in Mexico City, will team up with Dr. Eugene Lepeschkin, University of Vermont, to present the three-day course in Advanced Electrocardiology. The course fee is $50.00. Applications should be made to Office of Medical Extension, University of Nebraska College of Medicine, 42 and Dewey, Omaha 5, Nebraska.

DOCTORS' NURSES ORGANIZE

The American Association of Doctors' Nurses, a new non-profit association, has been incorporated to assume the membership of the old American Registry of Doctors' Nurses. This measure has been taken in order to eliminate the legitimate objections of other nursing groups.

The purpose of the new association is to promote the welfare of its members, to elevate the standards and ethics of their profession, and to enroll doctors' nurses in order that they may advance their status as proven members of that profession.

The membership is composed of not only those whose experience has been entirely in doctors' offices, but also trained nurses and practical nurses who are not serving in hospitals, nor engaged in private duty, but are now serving in doctors' offices. At present there are members in forty-eight states, Puerto Rico, and the Republic of Panama.

The doctor's nurse must be able to qualify as an ex-

NATIONAL SOCIETY FOR CRIPPLED CHILDREN AND ADULTS OFFERS GRANTS

Research projects to aid children and adults crippled by cerebral palsy, neuromuscular diseases, paralysis and hearing losses and another to promote educational opportunities for them will be furthered by a new series of grants awarded by the Easter Seal Research Foundation.

Institutions receiving the new series of awards include:

American Academy for Cerebral Palsy

$2,500 to support a research conference on management in cerebral palsy planned by its Committee on Evaluation of Treatment to consider launching a study which would contribute to effectiveness of treatment of the crippling condition. The committee, chaired by William T. Green, M.D., Boston, Massachusetts, will conduct the conference at Princeton University in 1959. It will include representatives of the various "schools of therapy" now providing care to cerebral palsied persons.

University of Chicago, Department of Medicine, Section of Medical Psychology

$7,486.50 for conducting a study aimed at improving methods for evaluating mental and vocational educability of brain-injured children, including those with cerebral palsy. Directed by Ward C. Halstead, Ph.D., director of medical psychology, the project is titled "The Methodology for Objective Evaluation of Psychometrid and Biological Intelligence of Handicapped Children, Including Cerebral Palsy."

Eugene du Pont Memorial Hospital and Rehabilitation Center, Department of Physical Medicine and Rehabilitation, Wilmington, Delaware

$9,500 toward research for perfecting a lightweight mechanical hand to assist persons crippled by paralysis.

Northern Illinois University, Department of Speech

$2,500 to support the study, "A Comparative Analysis of the Language Development of Normal and Hard of Hearing Children," conducted by Louis Lerea, Ph.D., director of the speech and hearing clinic.

University of Tennessee College of Medicine, Division of Pediatrics

$4,668.29 toward research that may contribute to treatment of neuromuscular diseases. James N. Etteldorf, M.D., professor of pediatrics, and Harris L. Smith, M.D., instructor of pediatrics, are studying why and how metabolism of skeletal muscles is affected in these various diseases.

Western Interstate Commission for Higher Education, Boulder, Colorado

$7,500 to provide information toward planning for efficient expansion and improvement in training programs for special education teachers in the nation's West.

Woman's Auxiliary

AMA AUXILIARY MEETING ACTIVITIES HIGHLIGHTED

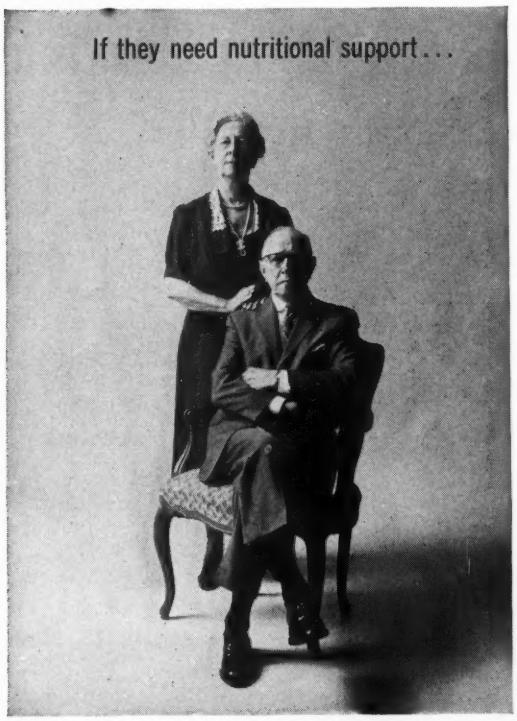
The thirty-sixth annual convention of the Woman's Auxiliary to the American Medical Association was formally called to order Tuesday, June 9, at 9:00 a.m. in the Vernon Room, Haddon Hall Hotel, Atlantic City, New Jersey. The meeting was opened by Mrs. E. Arthur Underwood, AMA Auxiliary President.

Included in the first day's activities was an address by Lt. Col. Ingalls H. Simmons, M.C. Colonel Simmons mentioned that turning a can of tomatoes or a box of crackers upside down and opening the end that sat on the shelf may save your life.

In the event of a thermonuclear attack, the Army physician warned never to take chances with food and water. "Radioactive fall-out material is just like dust," said Colonel Simmons, "the main problem is to keep fall-out from getting into your stomach where it can really do damage." Listing water, food and shelter as the three considerations that should be uppermost in the housewife's mind in disaster preparation, Colonel Simmons gave examples of safe emergency supplies and outlined steps to follow to keep the home as safe as possible.

Aubrey Gates, Director of the AMA Field Service, spoke on the subject, "Talking to Congressmen Back Home," at a luncheon honoring Woman's Auxiliary past presidents, and Dr. George M. Fister, Chairman of the AMA Council on Legislative Activities, was a guest speaker during an afternoon presentation on legislation.

Leading off the opening business sessions were Frank R. Burrows, Jr., Field Service Director of Chicago Citizens Traffic Safety, and Dr. Marvin A. Block of Buffalo, New York, Chairman of the AMA Committee on Alcoholism.



Dr. Gunnar Gundersen, immediate past AMA president, was the featured speaker at a luncheon honoring the retiring Auxiliary president, Mrs. E. Arthur Underwood, and the incoming president, Mrs. Frank Gastineau. Dr. Gundersen outlined the role of international medicine as an agent for peace.

Several films on medical recruitment and "Crusade for Freedom" were also shown.

Invocation was given by Rabbi Martin Weitz, Beth Israel Temple, Atlantic City. Greetings were given by Dr. David B. Allman, Chairman of the AMA Committee on Arrangements, and Dr. Louis Rosenberg, president, Atlantic County Medical Society.

Mrs. A. Guy Campo, president of the Woman's Auxi-

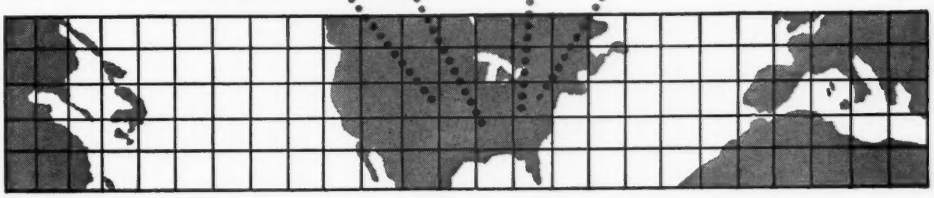
READ WHAT CLINICIANS ARE NOW SAYING ABOUT ATARAX®



(brand of hydroxyzine)

IN GERIATRICS
"ability to decide correctly has increased, while the illogical response to anxiety has diminished."[1]

IN WORKING ADULTS
"especially well suited for ambulatory patients who must work, drive a car, or operate machinery."[3]

IN PEDIATRICS
"ATARAX appeared to reduce anxiety and restlessness, improve sleep patterns and make the child more amenable to the development of new patterns of behavior. . . ."[2]

IN GENERAL
ATARAX is "effective in controlling tension and anxiety. . . . Its safety makes it an excellent drug for out-patient use in office practice."[4]

INVESTIGATORS AGREE ON OPTIMAL ATARAX DOSAGES

For childhood behavior disorders	10 mg. tablets	3-6 years, one tablet t.i.d. over 6 years, two tablets t.i.d.
	Syrup	3-6 years, one tsp. t.i.d. over 6 years, two tsp. t.i.d.
For adult tension and anxiety	25 mg. tablets	one tablet q.i.d.
	Syrup	one tbsp. q.i.d.
For severe emotional disturbances	100 mg. tablets	one tablet t.i.d.
For adult psychiatric and emotional emergencies	Parenteral Solution	25-50 mg. (1-2 cc.) intramuscularly, 3-4 times daily, at 4-hour intervals. Dosage for children under 12 not established.

Supplied: Tablets, bottles of 100. Syrup, pint bottles. Parenteral Solution, 10 cc. multiple-dose vials.

liary to the Medical Society of New Jersey, gave the address of welcome, and Mrs. Clarence Lyon, president of the Woman's Auxiliary to the Washington State Medical Association, gave the response.

Auxiliary Presents American Medical Education Foundation Gift

Medical education got a financial boost from the physicians' wives who make up the Woman's Auxiliary to the AMA.

A check for $137,291 was presented to the American Medical Education Foundation by Mrs. Karl F. Ritter, Auxiliary AMEF Chairman. Dr. George F. Lull, president of the Foundation, accepted the check.

The presentations were made at the luncheon in Haddon Hall honoring Mrs. E. Arthur Underwood, retiring Auxiliary president, and Mrs. Frank Gastineau, the new Auxiliary head.

Program events included presentation of AMEF awards by Dr. Lull to Auxiliaries that chalked up impressive records last year, and presentation of *Today's Health* subscription contest awards by Robert Enlow, circulation manager.

At a morning general meeting for members only, election of officers took place. Informal discussion of 1959-60 committee programs by the Board of Directors and national committee chairmen were slated for the afternoon.

Officers Named

Mrs. William Mackersie, Detroit, Michigan, was named president-elect of the Woman's Auxiliary to the American Medical Association, and Mrs. Frank Gastineau, Indianapolis, Indiana, took office as president.

In elections at the concluding business session at Haddon Hall, the Auxiliary also elected the following officers:

First Vice President, Mrs. Charles L. Goodhand, Parkersburg, West Virginia; Eastern Regional Vice President, Mrs. Paul E. Rauschenbach, Patterson, New Jersey; North Central Vice President, Mrs. Stephen Bachelle, Enderlin, North Dakota; Southern Regional Vice President, Mrs. Willis G. Thuss, Birmingham, Alabama; and Western Regional Vice President, Mrs. L. D. Jacobson, Eugene, Oregon.

Constitutional Secretary, Mrs. W. W. Hubbard, Nashville, Tennessee; Treasurer, Mrs. Harlan English, Danville, Illinois; Director (two years) Mrs. Roger A. Cheney, Springfield, Massachusetts; Director (two years) Mrs. Albert E. Goldstein, Baltimore; Director (two years) Mrs. Stanley R. Truman, Oakland, California.

Director (one year) Mrs. E. Arthur Underwood, Vancouver, Washington; Director (one year) Mrs. Shelley C. Davis, Atlanta, Georgia; Director (one year) Mrs. William H. Evans, Youngstown, Ohio; and Director (one year) Mrs. M. A. Gold, Butte, Montana.

Finance Secretary, Mrs. Harry F. Pohlmann, Middletown, New York; Historian, Mrs. George Turner, El Paso, Texas; and Parliamentarian, Mrs. Mason G. Lawson, Little Rock, Arkansas.

Vitamin-Mineral Supplement Lederle

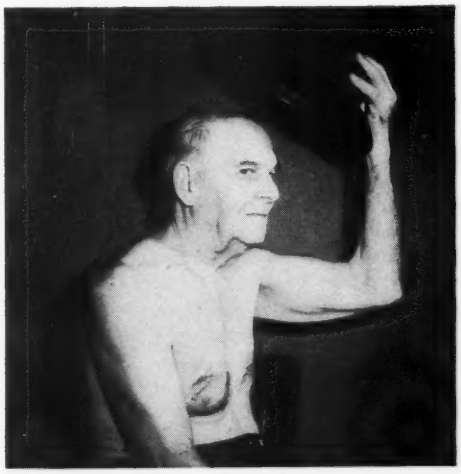
CAPSULES—14 VITAMINS—11 MINERALS

Each capsule contains:	
Vitamin A	5,000 U.S.P. Units
Vitamin D	500 U.S.P. Units
Vitamin B_{12} with AUTRINIC® Intrinsic Factor Concentrate	1/15 U.S.P. Oral Unit
Thiamine Mononitrate (B_1)	5 mg.
Riboflavin (B_2)	5 mg.
Niacinamide	15 mg.
Folic Acid	1 mg.
Pyridoxine HCl (B_6)	0.5 mg.
Ca Pantothenate	5 mg.
Choline Bitartrate	50 mg.
Inositol	50 mg.
Ascorbic Acid (C)	50 mg.
Vitamin E (as tocopheryl acetates)	10 I.U.
l-Lysine Monohydrochloride	25 mg.
Rutin	25 mg.
Ferrous Fumarate	30 mg.
Iron (as Fumarate)	10 mg.
Iodine (as KI)	0.1 mg.
Calcium (as $CaHPO_4$)	157 mg.
Phosphorus (as $CaHPO_4$)	122 mg.
Boron (as $Na_2B_4O_7.10H_2O$)	0.1 mg.
Copper (as CuO)	1 mg.
Fluorine (as CaF_2)	0.1 mg.
Manganese (as MnO_2)	1 mg.
Magnesium (as MgO)	1 mg.
Potassium (as K_2SO_4)	5 mg.
Zinc (as ZnO)	0.5 mg.

LEDERLE LABORATORIES, a Division of AMERICAN CYANAMID COMPANY, Pearl River, New York

For arthritic M.S.: full corticosteroid benefits from new Gammacorten T.M.

Patient M.S., 81, at the time of the first visit was in severe pain and very uncomfortable. Complained of swelling of wrists, legs and various joints; pain and stiffness in cervical area and lower spine; pain, swelling and limited motion in the fingers; slight ulnar deviation of the hand. M.S. demonstrates position necessary to put on his hat (motion was so restricted that he could not comb his hair).



Treatment and Result: After 36 hours of GAMMACORTEN therapy, M.S. had "complete relief." Joint swelling had decreased, pain was almost absent, range of motion had increased dramatically. At the end of the first week of GAMMACORTEN he was free of discomfort and able to return to his job as a porter. M.S. could put on his hat normally, could comb hair; joint function near-normal after first week.

Gammacorten T.M.
(dexamethasone CIBA)

- potent, effective corticosteroid
- profound anti-inflammatory activity
- minimal side effects

From the files of a practicing physician. Photographs used with permission of the patient.

SUPPLIED: GAMMACORTEN Tablets, 0.75 mg. (pink, scored).

The Physician's Diary

All officers of the Hennepin County Tuberculosis Association were re-elected for another term. Included are: **Dr. H. E. Drill,** president, and **Dr. Sumner S. Cohen,** first vice president.

* * *

Principal speaker for the ground-breaking ceremony of the new hospital in Aurora was **Dr. Richard Bardon,** of the Duluth Clinic, and president of the St. Louis County Medical Society. Dr. Bardon was introduced by **Dr. Richard Barnes** of the East Range Clinic in Biwabik.

* * *

Dr. Cleon R. Holland, of the Mayo Clinic, has left Rochester to practice medicine in Plainview.

* * *

Owners of the first medical building to be erected in Doctor's Park, Chaska, are **Dr. C. R. Heinzerling,** Chaska physician, and Dr. Edgar E. Ziegler, Chaska dentist.

* * *

Dr. Harry Burich, Rochester, recently attended a postgraduate course for surgical specialists in Kansas City, Missouri.

* * *

The member of Congress from Minnesota's Fifth Congressional District in Minneapolis, **Dr. Walter H. Judd,** has been re-appointed to serve on the Advisory Council of the United States Committee for the United Nations.

* * *

Blue Earth physician, **Dr. Bruce Sundberg,** has left that city for a practice in Heron Lake. Dr. Sundberg will be associated with **Dr. Gerald Kuss,** a former classmate who was with the U. S. Public Health Service in New York.

* * *

A former member of the Blue Earth Medical Center has returned to practice there. **Dr. Don V. Smith,** formerly surgeon with the center, will return there shortly to fill the vacancy left when Dr. Bruce Sundberg moved to Heron Lake.

* * *

A Mayo Clinic consultant, **Dr. Edward B. Waldmann,** has left Rochester to enter private practice in Phoenix, Arizona. Dr. Waldmann joined two other former Rochester doctors in Phoenix.

* * *

Wadena physician, **Dr. Luther Davis,** has announced that **Dr. Duane Ness,** Minneapolis, will be associated with the Davis Clinic in the near future.

* * *

Among six physicians recently named as consultants of the Mayo Clinic are **Dr. Philip J. Osmundson** and **Dr. Juergen E. Thomas.** Dr. Osmundson will specialize in Internal Medicine and Dr. Thomas in Neurology.

* * *

Dr. A. J. Lehrer, has announced his association in the practice of medicine with **Dr. F. C. Westerman** of Montgomery.

The new staff member of the Mork Clinic, Anoka, is **Dr. Matthew D. Yelle,** a native of Pennsylvania.

* * *

Dr. R. H. Puumala and **Dr. Marie Bepko Puumala,** Cloquet, attended graduation ceremonies for Ricard Puumala and their daughter-in-law, Barbara Meyer Puumala, from the University of Minnesota. Dr. Ricard and Dr. Barbara began their internship at St. Luke's Hospital following graduation.

* * *

Janesville physician and surgeon, **Dr. M. Clifford Florine,** has returned to Gorgas Hospital, Balboa, Panama Canal Zone, where he will complete the final two years of his residency in internal medicine.

* * *

A spring refresher course, sponsored by the Southern Minnesota Chapter of the Minnesota Academy of General Practice, was held recently in Faribault. Included as speakers on the program were **Dr. Elmer Paulson,** who discussed "Nuclear Medicine"; and **Dr. Harold Ravits,** whose topic was "Common Skin Disorders."

* * *

Elected as new chief of the medical staff of the Winona General Hospital, is **Dr. Sidney O. Hughes.** Also elected were: **Dr. D. V. Boardman,** vice chief; **Dr. Daniel Degallier,** secretary; **Dr. P. A. Mattison,** chief of surgery; **Dr. Warren W. Haesly,** chief of medicine and **Dr. L. J. Wilson,** chief of obstetrics.

* * *

Mayo Clinic staff men who have been honored recently include **Dr. H. J. Moersch,** who received the annual Rudolf Schindler Award of the American Gastroscopic Society. The award was presented by **Dr. A. M. Olsen,** Rochester, in Atlantic City, N. J., at the annual meeting. **Dr. E. A. Banner** was elected to the Executive Board of the Continental Gynecological Society in Kansas City. **Dr. R. B. Wilson** spoke at the recent Third World Congress on Fertility and Sterility of the International Fertility Association held in Amsterdam, Holland.

* * *

Dr. George Logan, Rochester, recently presided at a special committee meeting to work on a plan for a statewide school health council. Dr. Logan named **Dr. A. B. Rosenfield** as chairman of a subcommittee to draft a proposed charter for submission to interested agencies.

* * *

The superintendent of Cambridge State School has resigned his post to take another position in Tennessee. **Dr. George L. Wadsworth** will become superintendent of Clover Bottom home at Nashville and will also become director of research in a new research facility at Clover Bottom. Dr. Wadsworth will be succeeded at Cambridge by **Dr. Galen Adkins,** former superintendent of Sandstone State Hospital.

For Quality without Question... Enjoy the unique refreshment of sparkling Coca-Cola

SIGN OF GOOD TASTE

Dr. S. Marx White, Minneapolis, has been awarded the Northwestern University Alumni Association's Merit Award. The presentation, "in recognition of worthy achievement which has reflected credit upon Northwestern University," was made by Dr. Edgar Swanson, chairman of the Achievement Committee. Dr. White is one of the founders of the Nicollet Clinic.

* * *

Dr. Jack Gardner, Ceylon, will join his father, **Dr. V. H. Gardner,** in the latter's medical practice in Fairmont, later this summer.

* * *

East Range Clinic member, **Dr. J. Raymond Chittum,** has left Hoyt Lakes for Niagara Falls, New York, where he has accepted a position.

* * *

Speaking recently at a dinner of the state division of vocational rehabilitation was **Dr. Frank Krusen,** of the Mayo Clinic, Rochester.

* * *

Physicians from fifteen Minnesota mental health and other institutions were recent participants in a quarterly conference at the Faribault State School and Hospital. Presiding at the conference was **Dr. Dale Cameron,** medical director of the Minnesota Department of Public Welfare.

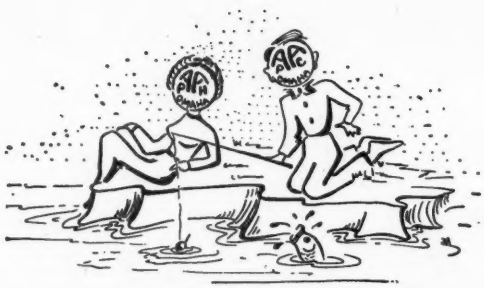
* * *

It has been announced that **Dr. Walter A. Fansler,** Minneapolis, has been made an Honorary Member of the Royal Society of Medicine (Proctologic Section) at the joint meeting of the Royal Society of Medicine and the American Proctologic Society in London.

* * *

Dr. Albert Fritsche, New Ulm, has been elected president of the Union Hospital Board of Directors. He succeeds George D. Erickson.

* * *



New member of the Willmar Clinic is **Dr. Harris P. Hinderaker,** formerly of Bird Island. Dr. Hinderaker is the seventh member of the medical staff at the clinic. Other members are **Drs. H. G. Bosland, W. E. Peterson, R. P. Michels, A. M. McCarthy, A. J. Ellinger, J. W. Docksey** and a dentist, Dr. J. J. Michels.

* * *

Among Mayo Clinic members appearing on programs in foreign countries recently are: **Dr. R. R. Kierland,** participant of the Fourth Congress of Dermatology in Lisbon-Coimbra, Portugal; **Dr. F. H. Krusen,** speaker at the Fourth Inter-American Rehabilitation Conference in San Juan, Puerto Rico; and **Dr. J. S. Lundy,** speaker at a meeting of the Ontario Medical Association in Toronto, Canada.

* * *

Dr. Donald Peterson, superintendent of Anoka State Hospital, has been honored with a certificate of appreciation from the Anoka Red Cross Chapter. Dr. Peterson's award was given for his activities in promoting the blood fund drive for that chapter.

Dr. George Logan, Rochester, has been named chairman of a special meeting of delegates from voluntary health agencies and state government agencies.

* * *

A symposium on diseases of the liver and bile passages was held recently in Fergus Falls. The event was sponsored by the medical staff of Lake Region Hospital and the Park Region District and County Medical Society. Speakers at the symposium included **Dr. Richard Varco,** University of Minnesota; Dr. Wm. Summerskill, Mayo Clinic; **Dr. George Hollenbeck,** Mayo Clinic; Dr. P. H. T. Thorlakson, University of Minnesota. **Dr. P. H. Rockwood,** president of Lake Region Hospital Medical staff presided at the morning session. **Dr. Henry Korda,** Pelican Rapids, presided at the afternoon session. Also taking part were **Dr. A. E. Sethre** and **Dr. Ward Shaver,** of Fergus Falls.

* * *

Dr. R. Drew Miller, Rochester, has been named assistant director of the Mayo Foundation for Medical Education and Research.

* * *

Floodwood physicians **Dr. Edward O. Jorgensen** and **Dr. James C. Trautmann** have ceased to maintain their Meadowlands office. They are continuing their practice in the Duluth office.

* * *

Dr. Norman B. Bloom, Minneapolis, was recently elected president of the Minnesota Chapter of the American Friends of the Hebrew University.

* * *

Belgrade physician, **Dr. Gene R. Savelkoul,** has purchased the Dr. G. F. Engstrom combination residence and medical clinic on Washburn Avenue. Dr. Savelkoul plans to continue his medical practice in the municipal building on the opposite side of the street, and will occupy the residence part of the building. The building was originally erected by **Dr. H. F. Slocumb** and was purchased by Dr. Engstrom in 1929.

* * *

Dr. C. Sherman Hoyt, who recently completed his specialties training in pediatrics at the Mayo Clinic, has joined Drs. Albert Schroeder, Hreidar Agustsson and Detlof Olson in the practice of pediatrics at 225 Southdale Medical Building, Minneapolis.

* * *

The Itasca Clinic was recently opened in Park Rapids by **Dr. Robert D. Schrantz** and **Dr. Everette J. Duthoy,** both of whom are new to Park Rapids.

* * *

Dr. Leo J. Furr, Bird Island, has announced his association with **Dr. George C. Bingham,** who has assumed partnership with Doctor Furr. Doctor Bingham formerly practiced in Chaska.

* * *

Dr. G. T. Midboe, Forest Lake, has announced that **Dr. Lawrence Purdie** is now associated with him in medical practice. Doctor Purdie has been medical officer in charge of the Cass Lake Indian Hospital in northern Minnesota for the past year.

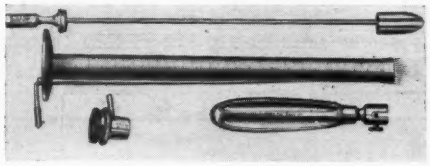
Book Reviews

FUNDAMENTALS OF OTOLARYNGOLOGY. By Lawrence R. Boies, M.D., Professor of Otolaryngology, Chairman, Department of Otolaryngology, University of Minnesota Medical School. 510 Pages. Illus. 3rd Edition. Philadelphia: W. B. Saunders, 1959.

The latest edition of this work is the third, of which translations have now been made into Spanish and Italian. The first edition (443 pages) was published exactly ten years ago, in 1949; the second (487 pages) came out in 1954 and the third (510 pages) was published this year. This gradual enlargement permits expansion of the text where necessary and also the addition of four new chapters, one dealing with maxillofacial injuries, another with reconstructive surgery of the nose, a third with tumors and swellings of the neck, and a fourth with diseases of the salivary glands.

The author's associates, each responsible for one or more chapters, are Anderson C. Hilding, Jerome A. Hilger, Conrad J. Holmberg, Douglas R. Kusske, Robert E. Priest, George M. Tangen, and Harold S. Ulvestad. The first two editions were dedicated to Dr. Harris P. Mosher, whereas this one is dedicated to Dr. Harold S. Diehl, former dean of Medical Sciences at the University of Minnesota.

The book is intended as a guide to the teaching of medical students, and also as a handbook for the daily use of physicians in general practice. It fulfills both of these purposes admirably. Both the text and illustrations are clear and to the point.



To this reviewer, who is a staunch believer in fundamentals, one of the best features of the volume is the inclusion of three chapters dealing in detail with the applied anatomy and physiology of the ear, the nose, and the throat. These are also extremely well written, and facilitate greatly the understanding of the text which follows.

The book fills an important place in the field of otolaryngology and is recommended to those who need help in this specialty.

Rehabilitation of the Cardiac Patient

Many aspects of the practice of medicine are aided by team effort. This report summarizes some of the earliest systematic studies of rehabilitation of the cardiac patient. Included are many practical suggestions as well as forthright statements of the philosophy and psychology of the care of the whole patient by the key man on the team—the private physician.

Presented at the Postgraduate Scientific Assembly sponsored by the Hennepin County Chapter, American Academy of General Practice, the Hennepin County Medical Society, and Lederle Laboratories, Minneapolis, January 12, 1959.

AMASA B. FORD, M.D.

Cleveland, Ohio

THE SUBJECT of this report is how to help people live with heart disease. I would like to start with a case history.

A fifty-four-year-old repairman suffered a myocardial infarction in March, 1956. After several weeks of hospitalization and progressively increasing activity he returned to his job repairing and maintaining road machinery, which he now does full-time without symptoms. Always a vigorous and hard-working man, he has gradually learned to let younger men help him with the heaviest work. Facing up to the fact that he cannot expect to do this type of work indefinitely, but knowing that he cannot tolerate inactivity, he has studied and obtained a license as a real estate salesman. He is gradually gaining experience in this new and less strenuous work and plans to change to it completely in the next year or two. When I talked to him recently, he said, referring to his heart attack, "That thing hit me an awful rap. Mom and Dr. Smith had their hands full for a while. When I woke up in the morning I'd say to myself, 'Well, I'm still alive today—I guess I'm going to die tomorrow.' But time went by, and I kept getting better, and I finally came to realize that when my time's going to come, it's going to come. There's no use worrying about it—you just have to go ahead and do the best you can."

That story describes the objective of cardiac rehabilitation in its simplest terms: To accept

and understand a serious disease state and to plan the most reasonable and full life possible within its limitations.

The general purpose of rehabilitation is no different from that of other forms of medical therapy. It has been called the "third phase of medical care" and "clinical after-care." The new element in the modern concept of rehabilitation is the recognition that interpersonal relations, emotional attitudes, and the social and economic environment may have as much to do with what an individual patient can achieve as the strictly medical aspects of his case. The President of the United States may survive a mild coronary occlusion at the age of sixty-five and return to work, but a sixty-five-year-old laborer in a steel mill, who recovers equally well from the same illness, cannot.

Rehabilitation of the patient with heart disease ideally takes place in four stages. First, the patient's medical problem is defined in detail. Second, trained health personnel in social work, vocational counseling and other fields are called upon when needed. Third, an orderly plan is made, and responsibility for carrying it out assigned. Finally, follow-up treatment and observation insure that the plan is carried through and adapted to changing events.

Defining the Medical Problem

The first step is evaluation. I don't intend to elaborate on diagnostic methods today except to say the obvious—that all subsequent stages of rehabilitation depend on an accurate diagnosis. It is often wise to defer advice and planning until laboratory tests, consultation, or time have clearly established the nature and extent of the heart disease or—and this is often important—its absence. Evaluation starts with a careful medical history and physical examination. The man with heart disease can often give a good description of his cardiac reserve by describing common activities which produce symptoms. These activities may be compared with the possible range of human activity and with the known energy requirements of work to determine safe levels of activity for the individual patient.

At rest, the adult human consumes about 250 cc. of oxygen a minute, which is equivalent to 1.25 large calories per minute. A champion athlete, using large muscle masses during sustained skiing or swimming for fifteen to thirty minutes, can expend 26 calories a minute, while the maximum energy expenditure for untrained young men running on a treadmill is about 14 calories a minute.[1] A group of German investigators measured the *maximum* energy expenditure of patients who had recovered from myocardial infarction and found them able to sustain an energy output of from 5 to 10 calories per minute.[2]

The energy cost of individual ordinary activities such as washing and dressing is in the range of 2 to 4 calories per minute.[3] Gardening, playing golf, or walking around the block requires 4 to 6 calories a minute, and cutting the grass, 5 to 7 calories a minute. I could hardly talk on this subject in Minnesota in January without mentioning snow shoveling, which can call for near-maximal exertion if the snow is wet and the shoveler eager. We must not forget the housewife, who can also expend a significant amount of energy in her work.

When we turn to the energy cost of work, individual activities are of importance when they exceed the tolerance of a worker with heart disease. Dr. Herman Hellerstein and I have made a series of observations on men with heart disease and control subjects at work in light metal manufacturing plants,[4] and we have subsequently expanded the study to include the more strenuous work performed in a steel mill.[5] We found two general patterns of energy expenditure. The desk or bench worker has a low, sustained level of energy expenditure with few peaks. Most modern factory workers, whether sedentary or standing at a lathe or automatic machine, exhibit a work pattern of this type. On the other hand, some jobs, particularly in the steel mill, show intermittent peaks of exertion like that of the fireman, but heavy work of this type is usually punctuated by frequent and often prolonged rest periods. The steel mill workers actually worked 55 per cent of the shift, while the men in the light metal manufacturing plants worked 65 per cent of the shift.

Peaks of exertion are important in making a work prescription for a cardiac patient, but we must also consider the sustained level of energy expenditure and its possible fatiguing effect. Average energy expenditure during the shift was low for those employed in light metal manufacturing—about 2 calories a minute—and rarely more than twice the resting rate. In the steel mill the average rates were higher; the men who tended the open hearth and blast furnaces averaged 3 calories a minute. Our studies show that the energy require-

ments of most modern industrial work are low and well within the capacity of many patients with heart disease. No difference in the rate or pattern of work could be demonstrated when the cardiac patients were compared with their healthy coworkers.

Work on the farm differs from factory work. The hours are longer, and certain tasks call for a greater expenditure of energy than all but the heaviest steel mill jobs. Because of the difference in work pattern on the farm, many farmers with heart disease reduce their activity as compared with healthy contemporaries.[6]

TABLE II. PREDOMINANT INFLUENCE OF EXTERNAL AND INTERNAL ENVIRONMENT ON PHYSIOLOGIC REACTIONS OF WORKERS IN A STEEL MILL

Physiologic Function	Predominant Influence			
	Exertion	Heat	Heart Disease	Anxiety
O_2 consumption	+			
Pulmonary ventilation	+			
Pulse	+	++	+	+
Blood pressure	+		+	
Electrocardiogram			+	

To summarize these remarks, Table I shows two scales of energy expenditure. Five calories a minute is the upper limit of sustained energy expenditure during daily work which can be tolerated by healthy men. This tolerance limit was proposed by German physiologists, and our studies tend to confirm it. The two most demanding jobs in the steel mill required an average energy expenditure of 4.25 and 4.75 calories per minute for the shift. The average sustained energy expenditure for most workers in a modern American factory is less than half this maximum. We believe that all Class II and many Class III cardiac patients can safely work at this level, that is, 2 to 2.5 calories a minute.

With regard to individual activities, a simple standard of comparison available to the physician is the Master two-step test. This exertion is equivalent to climbing and descending two flights of stairs in a minute and a half. The energy cost of the two-step test, as measured in our laboratory, is 8.5 calories a minute which would rate as heavy exertion on the scale.[7] A patient who can perform this test without abnormal changes in blood pressure, pulse rate or electrocardiogram should be able to perform safely most ordinary industrial tasks except for the heaviest type of manual labor. Most jobs which involve activities calling for more than 7 to 8 calories a minute can readily be modified to avoid such occasional exertions. If a patient can climb and descend two flights of stairs at an ordinary pace, he can do most industrial jobs equally safely.

TABLE III. "HEART WORK" AND ENERGY EXPENDITURE OF A STEELWORKER AND A SURGEON

	Energy Expenditure (Cal./Min.)	Working Increase In				
		Systolic BP (mm. Hg)		Pulse Rate (Beats/Min.)		"Heart Work"
Steelworker	4.4	10	×	61	=	6'0
Surgeon	3.0	80	×	35	=	2800

Total body energy expenditure, however, is only one of several stresses which determine the load on the cardiovascular system. Table II summarizes the conditions which we have found to have the greatest influence on certain physiologic functions. Oxygen consumption and pulmonary ventilation depend primarily on energy expenditure. Pulse rate is influenced by several factors, the most significant of which, in the steel mill, is heat stress. Marked increases in blood pressure and abnormal electrocardiographic changes, on the other hand, were observed mainly in individuals with known heart disease.

Recent studies at the National Institutes of Health indicate that the work of the heart, as measured by myocardial oxygen consumption, is closely correlated with blood pressure and heart rate. In studies on dogs, this correlation was demonstrated between myocardial oxygen consumption and the product of peak systolic blood pressure and heart rate.[8,9] We have observed increases of blood pressure and heart rate in certain surgeons at the operating table, where energy expenditure is generally low, which exceed the physiologic changes in the steel workers (Table III). If the product of heart rate and systolic blood pressure can be taken as a rough index of the work of the heart, it appears that it is possible for a surgeon working at an energy expenditure 30 per cent *less* than a steelworker to have an increase in heart work four or five times *greater*.

Data on energy expenditure, therefore, can serve to quantify one, but only one, of the major stresses which influence the cardiovascular system. A man with heart disease may or may not respond in an abnormal way to a given level of energy expenditure. Individual study of a man or woman with

heart disease remains the best way to determine his or her capacity to do the job. The patient's response to measured exercise in terms of blood pressure, pulse rate, and electrocardiographic changes can give important information and can be measured. Other physiologic changes, such as the output of adrenal hormones, epinephrine, and norepinephrine, and indirect effects on lipid metabolism may be of equal importance. We are just beginning to be able to measure some of these changes. Above all, we are just beginning to recognize that the changes in the body which condition health or disease are determined as much by what the job means to the workman as by how much energy it requires.

Social Evaluation

Standard clinical diagnostic methods and tests of function form the basis for definition of the problem. But for effective rehabilitation, the patient must also be studied in the light of his emotional and social characteristics. Traditionally, the small town family doctor has a profound knowledge of his patient's personality and social background as well as his medical condition. In a large city, however, the doctor, who may have specialized medical training and be able to provide effective forms of treatment, nevertheless lacks information about the patient's life outside of the office or hospital. The importance of such information has been so well expressed by Francis Peabody in his essay on "The Care of the Patient"[10] that I would like to quote what he says:

> Everybody, sick or well, is affected in one way or another, consciously or subconsciously, by the material and spiritual forces that bear on his life, and especially to the sick such forces may act as powerful stimulants or depressants. When the general practitioner goes into the home of a patient, he may know the whole background of the family life from past experience; but even when he comes as a stranger he has every opportunity to find out what manner of man his patient is, and what kind of circumstances makes his life. He gets a hint of financial anxiety or of domestic incompatibility; he may find himself confronted by a querulous, exacting, self-centered patient, or by a gentle invalid overawed by a dominating family; and as he appreciates how these circumstances are reacting on the patient he dispenses sympathy, encouragement, or discipline. What is spoken of as a "clinical picture" is not just a photograph of a man sick in bed; it is an impressionistic painting of the patient surrounded by his home, his work, his relations, his friends, his joys, sorrows, hopes, and fears.

Some of this information may be thrust upon the doctor by a fearful patient, some lies ready to the observant eye, but to get at certain serious troubles requires much time, patience, and skilled interviewing technique for which the busy practitioner or industrial physician has little time. Fortunately, consultants trained not only in the medical specialties but also in psychiatry, social work and vocational counseling are becoming increasingly available to the doctor and his patient with heart disease.

The second stage of rehabilitation has been greatly facilitated in the past seventeen years by the development of work classification clinics in major industrial centers throughout the country. These clinics, established and financed in various ways, are available to patients who have or are suspected to have heart disease and for whom a work prescription is needed. A work classification clinic, organized under the direction of Dr. Arthur Kerkhof, was recently opened in Minneapolis. I would like to describe to you the method of operation, and, later, summarize the experience of the Cleveland Work Classification Clinic which has been operating successfully under the direction of Dr. Hellerstein since 1950, because a new venture of this sort naturally raises many questions.

At the work classification clinic, the patient, who may be referred by any physician, undergoes a complete medical examination and is interviewed individually by members of a team. The team usually includes, in addition to a cardiologist, a social worker, a vocational counselor, a nurse, and sometimes other consultants such as a psychiatrist or a psychologist. Meeting in a round-table discussion, the team members then outline the patient's problem and draw up recommendations for work, activity, retraining, or further medical study and treatment. These recommendations are explained to the patient at a second interview and reported in detail to the referring physician. The work classification clinic, we believe, is an effective device to bring the skills of several disciplines to bear at one time on the problems of a patient with heart disease. But the use of a team approach to cardiac rehabilitation need not be confined to such clinics.

The ultimate responsibility for the patient's welfare remains in the hands of his physician. About three-quarters of the patients with heart disease can be successfully managed by their private physicians. But the physician is never alone in this undertaking. The middle-aged business-

man, flat on his back in the hospital with a "coronary," embodies the problems of cardiac rehabilitation and needs help with them long before he can attend a clinic. Everyone who enters his room participates in his care, whether consciously or not, and the skilled clinician begins to enlist the help of as many of these potential allies as possible from the first day of illness. Professional help is readily available in most hospitals from the nurse, the social worker, and the dietician. But all their efforts may be vain unless the patient's wife and children are given a sympathetic explanation of what is wrong, what the real dangers and hopeful prognostic signs are, and how important their attitudes and actions can be. The family, with the doctor, furnish the thread of continuity when the patient exchanges the strange and threatening hospital environment for that of his home and, later, when he makes his first ventures back into the world of normal activity.

Individual consultants may make important contributions to the management of patients with heart disease. Fifty-one per cent of the first 460 patients seen at the Cleveland Work Classification Clinic were judged to exhibit anxiety out of proportion to their medical condition, and 60 per cent had difficulty accepting their illness emotionally and intellectually. Adequate help in dealing with these problems can be provided by an attentive physician, but in occasional cases psychiatric treatment is required. The help of social workers, vocational counselors and others may be obtained by individual referral. A telephone call to the industrial physician or personnel manager may prevent misunderstanding on both sides. But in general, this type of piecemeal planning and consultation is less effective than a combined evaluation made during a face-to-face discussion, and leading to an integrated plan.

The Orderly Plan

The third aspect of cardiac rehabilitation is the making of an orderly plan. A patient with heart disease is always "managed," whether a plan exists or not. He may be held back by fear of activity, he may drift into self-pity and chronic disability because no one seems to care about the problem that threatens to overwhelm him, or he may be driven to exhaustion by a job for which he is ill-adapted. Chance circumstances, casual advice, or misinformation will "manage" the patient if the doctor doesn't. Again, the man ultimately responsible is the family doctor. The most careful team evaluation and planning may be ineffective unless it is clearly conveyed to the doctor. The plan must make sense to him and result in clear advice and orderly treatment.

The type of plan will be determined by the pattern of disease and modified by individual factors. The patient with rheumatic heart disease faces adjustment to a life-long and slowly progressive disability punctuated by episodes of heart failure or recurrent rheumatic fever. A reasonable plan for him may include retraining in a low-energy, highly skilled job which he can continue to hold during years of decreasing functional capacity. Surgical treatment at an appropriate time may be indicated and will certainly require emotional preparation and financial planning. An important part of the plan for many rheumatic patients is regular antibiotic prophylaxis against streptococcal infection.

The middle-aged man who suddenly develops the symptoms of coronary artery disease, on the other hand, needs help in dealing with abrupt, often apparently catastrophic, new factors in his life. He needs information and the reassurance that new knowledge of heart disease makes possible a more favorable prognosis. A plan for such a patient takes the form of a stepwise progression back to normal living, including medical treatment, dietary planning, evaluation of functional capacity at various stages, and vocational readjustment.

Follow-up

The fourth stage of cardiac rehabilitation, and in many ways the most important, is long-term consistent follow-up with periodic re-evaluation and adjustment of the plan to changing conditions. Again, the private physician remains the central figure. His task can be easier if he knows what to expect. Members of the staff at the Cleveland Work Classification Clinic have recently completed a follow-up analysis of the first 460 patients seen at the clinic.[11] These data represent the longest and most complete study of patients with heart disease referred for work evaluation. Because of the importance of such information in the rehabilitation of the cardiac worker, I would like to summarize the results briefly for you.

Of the first 460 patients, follow-up information was obtained on 433 (94 per cent), and the average follow-up was six years (range 4.6 to 7.8

years). The diseases seen most frequently were arteriosclerotic heart disease, hypertensive cardiovascular disease and a combination of the two. These three categories included 60 per cent of the patients. Twenty per cent had rheumatic heart disease. The patients were classified according to the Functional and Therapeutic Classification of the New York State Heart Association. A striking finding was that this rough clinical classification had prognostic value. Six-year survival rates were: Class I, 83 per cent; Class II, 61 per cent; Class III, 40 per cent; Class IV, 34 per cent. Other initial findings associated with a high mortality rate were an abnormal response to the Master two-step test (twice the mortality rate of those with normal responses), and a diastolic blood pressure above 120 mm. Hg (twice the mortality rate of those with diastolic pressures below 100 mm. Hg).

The patients were mainly white men (90 per cent), and they came to the clinic for advice regarding work or activity. Fifty-eight per cent were not working at the time of their first visit. The majority (54 per cent) were judged capable of returning to their previous job or to more strenuous work. Twenty-nine per cent were advised to do lighter work, 10 per cent needed evaluation of work tolerance, 19 per cent, further treatment, and 7 per cent were rated unemployable. (I might comment that more than one of the recommendations listed were made in some cases). The over-all work record at follow-up was good. Eighty-two per cent of the patients worked part or all of the period between first visit and follow-up or death. The most important factor interfering with work was heart disease, but those remaining employed lost only 3.8 days per 100 days for cardiac reasons and 1.9 days per 100 days for non-cardiac reasons, compared with a reported average of 3.4 days per 100 days' absenteeism for unselected workers. Education beyond grade school was associated with a better employment history. The soundness of the team approach to work evaluation was borne out by the fact that of those initially advised to continue or increase their work, 80 per cent were found to be employed at follow-up, whereas only one out of seven rated unemployable had been able to find work. Sixteen of the twenty patients referred for further vocational evaluation and training were working at the time of follow-up.

We believe that the experience of the Cleveland Work Classification Clinic demonstrates that consistent application of the principles of rehabilitation can result in sound planning and satisfactory work adjustment for the majority of patients, without ignoring the serious nature and far-reaching consequences of heart disease.

Joseph Fox, in his recent book, *The Chronically Ill,* [12] says:

> The story of man's response to the challenge of physical misfortune is really a universal one, and it is a thrilling story. Many responses to this challenge have been heroic; and many have been full of humanity, humor, resourcefulness and great courage and perseverance. It has not been all suffering. Much of it has shown the victory of man's spirit, which is the essence of life itself.

I would like to close by wishing success to your new work classification clinic and to encourage those of you in the audience who practice in the vicinity to make use of its facilities in planning for your patients with heart disease.

Fractures among Children

I. Parental Assault as Causative Agent

Presented before the Clinical Meeting, American Medical Association, Minneapolis, December 3, 1958.

DONALD S. MILLER, M.D., Ph.D.
Chicago, Illinois

Dr. Miller is Professor and Chairman of the Department of Orthopedics and Traumatology, Chicago Medical School; Professor of Orthopedics, Cook County Graduate School of Medicine; Chairman, Department of Orthopedics, Mt. Sinai Hospital of Chicago; Attending Orthopedic Surgeon, Cook County Hospital, Chicago, and Oak Park Hospital, Oak Park, Illinois.

FRACTURES from parental assault have received only scattered recognition of what they actually represent: deliberate or careless trauma inflicted on children by delinquent adults. Caffey[1] and Silverman[2] have surmised the origin of injuries among children from this type of traumatic experience but Caffey, so far as I know, has not submitted his supposition in print. Silverman has been emphatic about it. An excellent critical review and comprehending analytic study of the etiologic problem was made in 1955 by Woolley and Evans[3] of Detroit. Their study covered cases of bone lesions found in many children, among whom twelve met their criteria of belonging to "injury-prone environments," environments in which at least one adult was psychotic or neurotic and in which every household was unstable in one manner or another. The children had had multiple areas of injury to bone, cumulative over a prolonged period, in conjunction with injuries to other tissues. Woolley and Evans cogently refuted Astley's deduction regarding fragility of the metaphyseal bones of infants which Astley saw as the common denominator pointing to causation, notwithstanding the concurrence in his cases of "bruising, retinal separation, compression of vertebrae, and multiple (ordinary) fractures."

Bakwin[5] likewise doubts Astley's fragility hypothesis "in view of the normal appearance of the unaffected bones, the smooth healing process and the normal subsequent development of these children . . . [with] subperiosteal ossification, metaphyseal fractures, avulsions, gross fractures, impacted fractures, and epiphyseal displacements"—all of traumatic origin, deliberate or through neglect, without a doubt when the accompanying circumstances are taken into account. Jones and Davis[6] summarized thirty-seven reported cases of "multiple traumatic lesions of the infant skeleton" and added descriptions of five of their own cases, in which they also urged the initial provisional diagnosis of traumatic experience when clinically collateral symptoms are suggestive, rather than to assume an underlying disease, perhaps of obscure etiology.

Congenital or acquired underlying diseases of children which lead to pathologic disturbances of bone are not too mysterious to identify. The likeliest of these are scurvy, rickets, syphilis, tuberculosis, malignancies, and some of the blood dyscrasias, such as leukemia, Letterer-Siwe disease and Cooley's anemia. Fractures of clinically uncertain origin among children have often been presumed to be the result of scurvy, rickets, or syphilis; but these are now rare diseases of children, although the possibility, particularly regarding scurvy, among these three conditions, may not be dismissed in differential diagnosis when the cause cannot be established by the history. As Silverman[2] pointed out, it is noncontributory and naïve to make extensive laboratory studies when the cause is obvious. Biochemical testing to disclose the reason for bruising, hemorrhages, ecchymoses, and fractures on the presumption that they are of

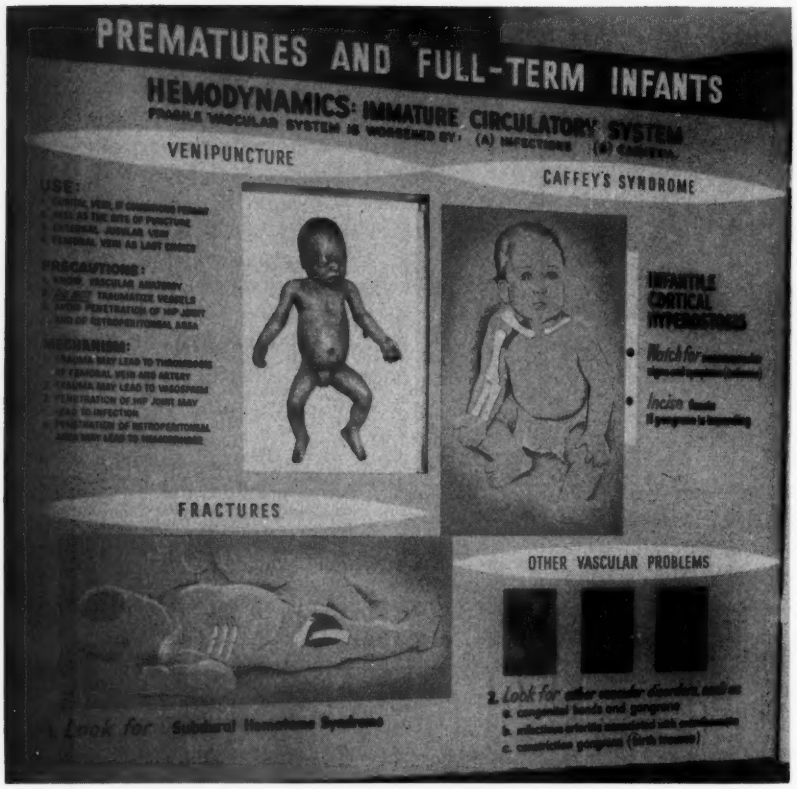

Fig. 1. Circulatory changes associated with orthopedic disorders. Note subdural hematoma syndrome and infantile cortical hyperostosis (Caffey's syndromes).
From exhibit of Circulatory System Changes Associated with Orthopedic Conditions prepared by the author and Rowlin Lichter, M.D.

pathologic origin is wasteful when the cause is plain at the outset to the alert examiner.

Regarding Caffey's syndrome, I believe that subdural hematoma (Fig. 1) is certainly of traumatic origin. Infantile or congenital cortical hyperostosis (Fig. 1) may be confused with traumatic periostitis unless history-taking is thorough. Friedman[7] has called attention to the resemblance between the two conditions.

When maltreated children are tended in the hospital, they gain weight rapidly, because they eat ravenously—evidence of previous neglect as the cause of malnourishment and nutritional anemia, which are almost always conditions concomitant with the fractures and bruises. When such children are removed from harmful environment, new lesions do not appear and the old ones heal uneventfully.

On November 10, 1958, the newspapers carried the story of an 18-month-old child who was slapped by his father for bed wetting and became paralyzed on the right side. The hospital diagnosis was said to be a brain hemorrhage. The father insisted that his "slap did not do it" but that the child who was just learning to walk had fallen in the kitchen "and got a big lump above his nose," as the man put it. But there were bruises reported over other areas of the face and on the hands. On November 21, 1958, a headline in the Chicago *Daily News* read, "Parents Get Life in Baby's Death." The child, who had been beaten by an Indiana couple who testified that they "didn't like girls," died of a broken arm, skull fracture, and severe burns and bruises over the body. And another infant daughter, according to the story, died of malnutrition several years ago. These are extreme examples that make the headlines. What about the less severe cases that go undetected?

Because general practitioners treat 60 per cent of the simple fractures, they must be quick to iden-

tify the presenting appearance of strange multiple associated injuries. *Suggestive lesions should make parents suspect*—or their baby sitters or their older siblings or, as social workers' case studies show, the lovers of irresponsible guardians who maltreat the children when children discover their clandestine meetings or are otherwise in the way. The sociologic implications, then, as well as the needs and plan of treatment, require that the attending physician be careful and perceptive in ascertaining the cause of the injury. When the physician sees a child who has multiple injuries over many areas of the body, in which the fractures are not consistent with the conditions observed in a fracture that is truly the result of an unavoidable accident, the physician should recognize the possibility of deliberate assault or of failure to be protective (Fig. 2).

The customary fall from a chair, hobby horse or bicycle causes a single fracture. In the typical fall from heights, such as from porches or windows, outsiders witness the accident, and the fracture, as a rule, is unilateral and of the crushing type. *It is the multiplicity of the injuries from aggressive assault that casts doubt on the story of accidental occurrence told by the parent or guardian.* Fractures from assault are not necessarily multiple, although they often are; but they *are* always associated with other multiple injuries to the soft tissues: welts, bruises, burns of the face and neck or buttocks, abdominal tenderness because of visceral injuries, as from a kick, and frequently, subdural hematomas. The presence of either a hematoma or a fracture accompanied by other disorders should incite the search for the disturbance that is not at once apparent.

On immediate roentgenographic examination, only the obvious fracture may be observed. Somewhat later, a roentgenologic survey may disclose a hidden skull fracture, or small fractures near the epiphysis or metaphysis, or fractures of several ribs. The survey may also reveal healed old fractures. Other signs of neglect are also evident at once: malnourishment and the general physical appearance of untidiness.

This is where adroit elicitation of the history to confirm the suspected cause of injury becomes essential. History-taking must not be routine; it must not be perfunctory; it must not be the duty of the inexperienced; it must be painstaking and probing. The child in many cases cannot speak for himself; he is either too young or too frightened to tell what really happened. The immature adult who speaks for him, no matter how evasively, cannot long elude a knowing interrogation. The examiner, however, must guard against having an accusing attitude, so as not to lose control over the case before constructive measures can be accomplished, and particularly so that in the meantime the child will not become the target of vengeance.

Fig. 2. Parental assault may cause fractures, multiple hemorrhages, brain injury, skull fracture, burns, blindness. Their true cause may be difficult to ascertain except by shrewd history-taking and observant examination of all signs of violence.

What can the physician do when he is convinced of the cause of a child's injuries? Woolley and Evans[3] at first told the parents that they were aware of the unwholesome situation but offered to be helpful in resolving the family problem without "punitive" action; later, they tried enlisting the aid of social agencies, but this was not satisfactory because the families would move away out of reach, and in one instance, the child died of head injuries while the case was being investigated. Their subsequent policy became one of attempting by co-operative efforts to have the child removed from the household first, before the home environment was surveyed by authorities.

In large cities, injuries to children inflicted by cruelty or through indifference, or under alcoholic (Fig. 2) or psychotic behavior, seem to come to the attention of hospital personnel in cycles coinciding with the sporadic influxes of migratory workers and

vagrants. Such disturbing situations become the social interest not only of psychologists and psychiatrists and juvenile authorities and courts of law

Fig. 3 (Case 1). Parental assault fractures of the humerus and both bones of the left forearm. Child had previously suffered injuries to head with loss of sight.

but of general practitioners, pediatricians, and orthopedists who must treat the bodily hurts. At the Cook County Hospital, the records of children admitted with such injuries are referred to the Social Service Department or to a public assistance agency. The Family Court is informed by phone and by a detailed explanatory letter regarding the medical and social problem. In most instances, the Juvenile Protective Association assumes responsibility for evaluation and disposition of the child to a foster home.

Injuries to children from assault and neglect are not limited to indigent and ignorant families. When they are observed in private practice among the more economically favored, the problem, in a sense, calls for more delicate handling but nevertheless demands the physician's social intervention if the child is to be saved and society is to be spared. Dr. Karl Menninger believes that every criminal was an unloved and maltreated child. The criminal is the child who survives his maltreatment physically alone. The child of a family in a higher financial bracket than children seen in charity hospitals, who suffers at the hands of an unrestrained, aggressive, or psychotic adult, can be helped by enlisting the co-operation of a temperate member of the family to resolve the problem.

Reports of Cases of Assault

Case 1 (Fig. 3).—D. D., a colored boy, aged two years, was admitted to Cook County Hospital on May 10, 1958, because of a head injury and epileptiform convulsions and loss of sight which the mother said was caused by falling from a chair. The child improved and was discharged on July 12, 1958, but was readmitted on August 24 because of two fractured arms and what appeared to be cigaret burns over the buttocks. The mother reported that the child had fallen from his crib three days before admission.

Roentgenograms showed a fracture of the middle third with outward displacement of the distal fragments of the right humerus and a fracture at the distal third of both bones of the left forearm. The right arm was put in a hanging cast; the left arm was reduced and then immobilized with a plaster cast which was removed on September 15, 1958.

Following an investigation which proved the mother's neglect of the patient, arrangements were made for the patient and four other children to be placed in the home of the maternal grandmother.

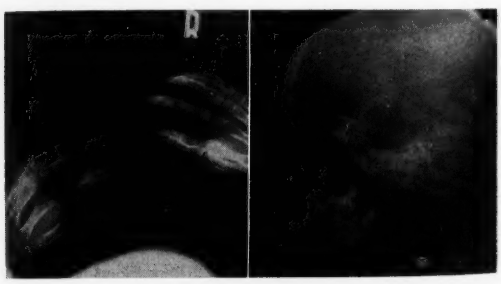

Fig. 4 (Case 2). *(left)* Linear fracture of right middle finger; proximal phalanx in good position. *(right)* Linear fracture of the right frontal bone without depression. Patient also had a hematoma of right orbit.)

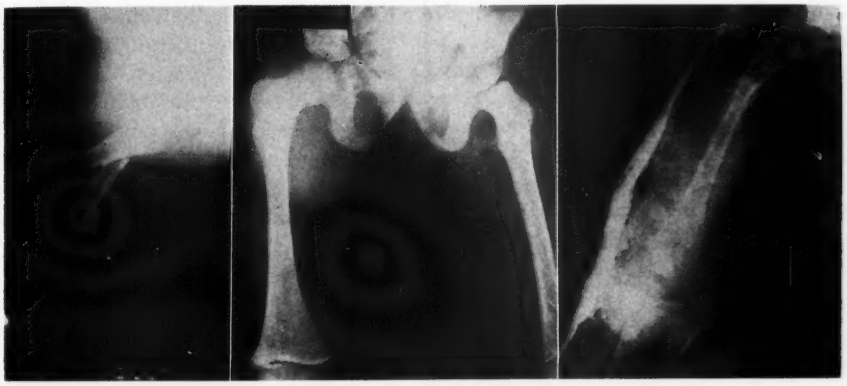

Case 2 (Fig. 4).—D. McG., a white girl, aged seven years, was admitted to Cook County Hospital on September 6, 1958, because of a possible skull fracture and apparently a fractured right arm which had occurred one hour before admission, when the patient's mother hit her with a baseball bat on the head and arms. Roentgenograms showed a linear fracture of the right frontal bone without depression, and a linear fracture of the right middle finger; the proximal phalanx was in good position.

The child's father told the social service worker that the mother had occasional outbursts of anger during which her hostility is always directed toward the patient. The mother is under psychiatric care. Both the psychiatrist and the attending physician recommended to Social Service that the child not be returned to her home but that at the time of discharge she be placed temporarily in the home of the father's niece. The case is being referred to the Juvenile Protective Association at this writing.

Case 3 (Figs. 5 and 6).—J. R., a colored girl, aged three years, was admitted to Cook County Hospital on August 8, 1958, because of a fractured leg incurred five hours before admission when the father intentionally stepped on the child and at the same time hit a sibling with a stick in "a fit of anger."

Roentgenograms showed a fracture of the left femur at the upper third with posterior displacement about 1 cm. and overriding and lateral angulation of the distal fragment. Bryant's traction was applied after manipulation. A hip spica cast was applied on August 27 and removed on September 28. There was some shortening of the left leg which measured 41.5 cm., the right leg measuring 43.5 cm.

The mother reported that the children annoy the father and that he frequently beats them for the slightest misdemeanor. The case has been referred to the Juvenile Protective Association, as protection of the five children is necessary.

Figs. 5 and 6 (Case 3). A girl, aged three years, was intentionally stepped on by her father, causing fracture of left femur at upper third with posterior displacement of about 1 cm., and overriding and lateral angulation of distal fragment.

Case 4 (Fig. 7).—S. T., a colored girl, aged six weeks, was admitted to Cook County Hospital on June 9, 1958, because of fractured ribs and a possible skull fracture, apparently caused by the mother while sharing the same bed with the infant whom she denied having assaulted; although the rib fractures associated with the skull fracture were typical of traumatic assault.

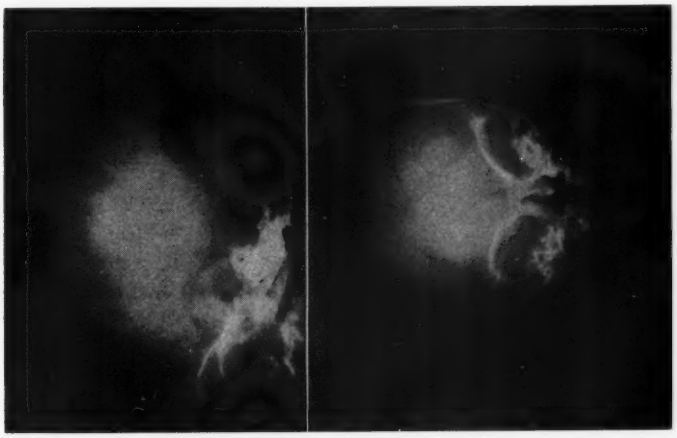

Fig. 7 (Case 4). Occipital fracture of skull incurred when child was kicked out of bed.

Roentgenograms showed fractures of the right posterior sixth, seventh, eighth, ninth, and tenth ribs, and six posterior left ribs which had partly healed in good position; there was also an occipital fracture of the skull.

The mother, who was nearsighted, withdrawn, and immature, at first said that she had possibly kicked the child in her sleep; later, she said that she had dropped the baby and then admitted that either she or her boy friend had kicked the baby out of bed. The case has been referred to Family Court.

Stereotactic Surgery in Parkinson's Disease

Supported in part by a research grant from The Sister Elizabeth Kenny Institute and by U.S.P.H.S. Grant #B-1158.

R. H. STRASSBURGER, M.D.
L. A. FRENCH, M.D.
Minneapolis, Minnesota

From the Division of Neurosurgery, Department of Surgery, University of Minnesota Medical School, Minneapolis 14, Minnesota.

STEREO-ENCEPHALOMETRY, or stereotactic surgery, is the term given to the surgical technique in which circumscribed, destructive lesions are placed in subcortical ganglia or pathways with negligible injury to adjacent structures. This is accomplished through the use of electrodes whose placement in the depths of the brain are precisely determined by mechanical guides. The use of mechanical devices for the production of discrete destructive lesions within the brains of experimental animals has been a common and familiar method in neurophysiologic laboratories for almost eighty years but only recently (since 1947) has it been adapted to humans. Many such devices have been constructed, most of which are variations of the Horsley-Clarke stereotactic apparatus first described in 1908.[1]

The stereotactic method, as applied to animal experimental work, depends for its accuracy and precision upon a fixed skull size and shape, and cannot be used in those animals exhibiting appreciable variation in skull architecture. The reason for this is that the method relies upon a constant correlation between external skull landmarks and internal brain structures or targets. Animals such as cats and monkeys do have a reasonably constant skull size and shape, and consequently are widely used for neurophysiologic investigation —on the contrary, the dog's skull architecture is notoriously variable, and therefore, its use is sharply limited by this factor. Unfortunately, at least in this respect, the human skull is also subject to a wide variability in size and shape, and indeed, even the internal structure of the brain itself exhibits a distressing variability. This has been the most important factor precluding the use of the stereotactic method in humans, and is the chief reason for the eighty-year delay in the adaptation of this technique for subcortical surgery in the human.

On the theory that stereotaxis could be practically applied to the human, if *internal* brain landmarks or reference points were used, Spiegel and Wycis,[2] developed such a method and reported its successful use in 1947. Originally, they used the pineal gland as a reference point, however, the unreliability of that structure has been amply demonstrated, and more dependable reference points are now used. The earliest application of stereotaxis to the human by Spiegel and Wycis[3] was in the field of psychosurgery. Lesions were placed in the dorsomedial nucleus of the thalamus, thereby achieving a lobotomy effect with minimal intellectual deterioration. Encouraged by successes in this venture, they then placed lesions in the mesencephalic spinothalamic tract for pain problems. Since their original report in 1947, it has become evident that the stereotactic method can also be used to advantage in such diversified problems as diseases of abnormal movements and subcortical epilepsy.[4,5] A number of stereotactic instruments have been devised and described by others and fairly large series of cases in each of the categories mentioned above have been reported, so that human stereotaxis, although still in its infancy, can now be considered beyond the theoretical stage.

The recent upsurge of interest in basal ganglia surgery for diseases of abnormal movements led to an interest in the sterotactic method by members of the Division of Neurological Surgery at the University of Minnesota Hospitals. To date, twenty-seven operations have been carried out on twenty-two patients with problems including seizures, and psychosis. Obviously, the comparatively small number of cases and relatively short period of follow-up — the longest being fifteen months—precludes the development of statistically

valid conclusions. However, it is felt that much can be gained by a consideration of our experiences to date, particularly in the group comprised of patients with Parkinson's disease.

Parkinson's disease, first described by James Parkinson in 1817, is actually a complex of symptoms or a syndrome. Clinically, the constellation of symptoms includes alternating tremor, cogwheel rigidity, mask-like facies, dysarthria, kyphosis, gait disturbance, poverty of movement, and disturbances of autonomic function. The two cardinal features, however, are tremor and rigidity, and most of the other symptoms mentioned can be explained on the basis of these two. The pathological changes associated with Parkinsonism are widespread and involve the central structures from the basal ganglia and thalamus rostrally through the reticular formation to the pons and medulla caudally. Even the cerebral cortex may be involved. There is no one specific site in which a lesion can be placed, or in which one has been found, that will account for the clinical picture. This clinical complexity should indicate that a single anatomical and physiological basis for all the stigmata of Parkinsonism will, in all likelihood, not be found. Even the etiology has remained a controversial point up to this time.[6] Inflammatory and toxic encephalitis, cerebral arteriosclerosis, post traumatic encephalopathy, and a number of other causes have been implicated. It seems clear, however, that of the estimated 400,000 sufferers of Parkinson's disease in this country, the majority are more or less clearly related to the 1917-18 influenza pandemic.

In spite of these complexities, an understanding of the patho-physiology is now beginning to emerge. Within the past few years, several laboratories have demonstrated that in the experimental animal an alternating tremor can be produced either by stimulation or by discrete destructive lesions within the bulbar reticular formation.[7,8] Moreover, stimulation or coagulation within certain of the basal ganglia, particularly the globus pallidus, effectively alters the tremor thus produced.

Attempts at surgical alleviation of abnormal movements began at the turn of this century when Sir Victor Horsley[9] reported the alteration of abnormal movements in an adolescent male by resection of a portion of the contralateral motor cortex. In the ensuing years, many additional reports of cortical ablations have been recorded.[10,11,12] It is the opinion of Bucy[13] and others that such cortical extirpations are inevitably followed by a spastic hemiparesis, and hence entails exchanging one serious neurologic disorder for another. Many other approaches to the problem have been tried, including section of a portion of the internal capsule,[14] partial section of the cerebral peduncle,[15] hemisection of the cord,[16] postero-lateral cordotomy,[17] sympathectomy,[18] and even prefrontal lobotomy. None of these procedures has been found entirely satisfactory. Each has had specific drawbacks, some sufficient to make the procedure unjustifiable. Then, Cooper[19] reported initially gratifying results from the ligation of the anterior choroidal artery and later from injection of destructive solutions into the basal ganglia in patients with Parkinson's disease. His enthusiasm was contagious. Subcortical surgery began to emerge as the most promising venture in the surgical alleviation of tremor and rigidity. Although an imposing number of cases of basal ganglia surgery have been reported by various authors in the past five years, it is felt that many important questions remain as yet unanswered. It is for this reason that the present project has been undertaken.

Inasmuch as Parkinsonism afflicts the young as well as the old, and exhibits a wide variety of clinical features in varying degree, there seems to be little value in attempting to define the classical case. Consequently, an investigative series must be an unselected one and must include the many natural variations which occur. In the series presented here, the chief indication for surgery is the presence of incapacitating tremor or rigidity —either unilateral or bilateral. Contraindications are limited to three: (1) general medical contraindications; (2) mental deterioration; (3) physiologic old age. It is hoped that as a result of this study it will be possible to define more accurately the indications and contraindications for this type of surgery. Preoperative and postoperative evaluations have been conducted in association with Dr. A. Iannone, Division of Neurology. These include detailed neurological examinations, electroencephalographic studies, and motion picture analysis. In addition, detailed objective measurements of tremor, rigidity, and motor functions are carried out at predetermined intervals by Dr. D. Webster at the Minneapolis Veterans Administration Hospital. The techniques involved in these various studies are rather complex, and will be

the subject of future reports; consequently, comment will be limited at this time. However, it should be noted that although a certain amount of reliance is placed upon the estimates of the patient and his family concerning degree of disability, degree of improvement, and so forth, the detailed objective data supplied by these studies is of invaluable assistance in the overall study of each case.

In this clinic, the Spiegel-Wycis method of stereotaxis has been adapted; and since it has been reported in detail elsewhere,[20] only the salient features will be discussed at this time. The procedure is carried out in two stages, the first under general anesthesia, and the second under local anesthesia. The first stage is devoted to obtaining accurate x-ray studies necessary for the localization of the intracerebral target. The second stage is devoted to study of the target area by means of stimulation and observation of the clinical response, patterns of evoked potentials, and under the usual circumstances, destruction of the target by means of electrocoagulation.

Through pneumoencephalography, two intracerebral reference points are routinely identified—these are the anterior and posterior commissures of the third ventricle. They are convenient reference points for the following two reasons: first, they are readily demonstrable in a conventional pneumoencephalogram and second, they are in close proximity to the usual target points within the basal ganglia. This latter point is especially important because the value of any structure as a reference point varies inversely with its distance from the target. Error is considerably minimized through the use of two reference points rather than one. Dr. H. O. Peterson has been of invaluable assistance in directing and contributing to this aspect of our investigation. With the information thus derived, it is possible to plot geographically the area representing any desired subcortical structure. A brain atlas, carefully conceived and devised, must be used in doing this. It is respectfully admitted that considering the variability in brain structures which has been demonstrated to exist by numerous investigators,[21] one cannot predict the configuration of a given structure which will hold for all patients. That is to say, should one make a lesion of sufficient size to destroy 100 per cent of the globus pallidus, it is inevitable that in a certain percentage of patients a portion of that lesion will actually fall outside the globus pallidus and injure adjoining structures. However, it is possible to plot an area which will represent a portion of the desired structure in *every* instance without danger of encroachment on the adjoining structures. The approach used in this clinic is to concern ourselves primarily with this constant target area; and should this prove insufficient for good clinical results, the marginal zone will be probed with stimulation at a later date.

TABLE I. SUMMARY OF DATA ON FOURTEEN CASES OF PARKINSON'S DISEASE

Patient	Age	Laterality	Duration of Symptoms	Clinical Result
R.C.	41	Unilateral	6 yrs.	Excellent
L.L.	47	Unilateral	20 yrs.	Excellent
H.F.	55	Bilateral	5 yrs.	Good
P.F.	57	Bilateral	38 yrs.	Fair
R.L.	49	Bilateral	20 yrs.	Good
R.H.	58	Bilateral	6 yrs.	Good
E.W.	51	Bilateral	10 yrs.	Good
V.M.	47	Bilateral	20 yrs.	Good
N.F.	61	Bilateral	25 yrs.	Fair
H.L.	70	Unilateral	5 yrs.	Excellent
L.J.	49	Bilateral	20 yrs.	Poor
W.S.	41	Bilateral	8 yrs.	Excellent
F.D.	66	Bilateral	3 yrs.	Poor
R.O.	55	Bilateral	31 yrs.	Fair

The actual technique is, in itself, not tedious. An electrode carrier is used which is fastened to the patient's skull by means of implanted stainless steel screws. The carrier is graduated in all planes in millimeters and in degrees to obtain maximum versatility. The screws are countersunk in the skull and remain in place permanently. This permits, at any time, re-application of the instrument in exactly the same position, utilizing the original co-ordinates and without the necessity of repeated air injections. A fine electrode, 1.2 mm. in outside diameter, is used. With it, one may obtain electograms or it may be used for stimulation or coagulation. It is even adaptable to the injection of fluid substances. For purposes of coagulation, we have routinely used direct, anodal current. In the laboratory, we have found that 10 milliamperes of current applied for one minute will produce an area of coagulation which is ovoid in shape and measures approximately 4 x 2 mm. in size. A planned pattern of such lesions is used to produce larger areas of destruction with some degree of axial orientation.

Table I summarizes the data up to this time on the fourteen cases of Parkinson's disease which have been studied and in which the patients have been subjected to pallidotomy. Several points are worth noting: the age range is from forty-one years to seventy years, with the majority being in

the sixth decade of life. Only three patients had essentially unilateral disease while in eleven it was distinctly bilateral in distribution. Duration of the disease varied widely, from a minimum of three years to a maximum of thirty-eight years. The last column represents a consensus clinical estimate of the therapeutic result in regard to tremor and rigidity. Four patients are classed as excellent, representing 95 per cent or better reduction of both tremor and rigidity. Five patients are classed as good, representing 66 per cent to 95 per cent reduction of symptoms. Three patients are classed as fair, representing 33 per cent to 66 per cent reduction of symptoms. Two are classed as poor, one because of a permanent hemiparesis, the second because of death which occurred two and one-half weeks postoperatively following a pulmonary embolus. It should be noted that age and duration of disease, while undoubtedly influencing the results of surgery, do not necessarily preclude satisfactory results. The oldest patient in the series, age seventy, is classed as an excellent result. Three patients with symptoms of twenty years or more duration are classed either as good or excellent.

TABLE II. COMPLICATIONS

Patient	Age	Duration of Disease	Complication
H.F.	55	5	Mental change, temporary
P.F.	57	38	Pseudobulbar palsy
L.J.	49	20	Permanent hemiparesis
F.D.	66	3	Death from pulmonary embolus 16 days postoperative
R.O.	55	31	Homonymous hemianopsia

Table II summarizes the complications which have followed pallidotomy. Following is further explanation of the first three complications in Table II. The remaining complications are self-explanatory.

Case Reports

Case 1.—H.F., aged fifty-five, the only bilateral pallidotomy in the series, underwent his first operation uneventfully. However, following a pallidotomy on the second side, which was carried out one month later, he experienced a curious alteration in mental abilities. While retaining an I.Q. of 117, he exhibited judgment and emotional content at about the five-year-old level. This persisted for a period of three months, when he reverted rapidly to normal status.

Case 2.—P.F., aged fifty-seven, had advanced disease of thirty-eight years' duration. In addition, he exhibited a hemiparesis as a sequel of encephalitis which he had had prior to onset of the Parkinson's disease. Following unilateral pallidotomy, he exhibited a persisting pseudobulbar palsy.

Case 3.—L.J., aged forty-nine, suffered an apparently permanent hemiparesis of moderately severe degree.

Table III concerns that single factor in which the patient and his family are most interested—rehabilitation. Considered realistically, this means different things to the patient who is confined to a wheelchair, incapable of self-care, than to the patient who is working every day in spite of a handicap. The ability to feed himself is a major gain for one, while another takes this for granted.

TABLE III. REHABILITATION

	Excellent	Good	Fair	Poor	Total
Significant gains	3	4			7
Minimal gains but more comfortable	1	1	2		4
Worse			1	1	2

Considered in this light, we have simply tabulated the patients in terms of "real gain" over and above their capabilities prior to surgery. As is readily apparent from the figures, significant gains in rehabilitation were made by only half the patients. Particularly impressive is the fact that *good or excellent reduction of tremor and rigidity is not synonymous with rehabilitation.* The factor of motivation is of paramount importance in this regard, and remains exceedingly difficult to evaluate, both preoperatively and postoperatively. Related to this is one important question which we hope to answer eventually; namely, should this type of therapy be restricted to those most likely to utilize it for significant gain in rehabilitation, or is the comfort of the patient in itself a legitimate indication? The tendency in most clinics at the present time is to confine efforts to the former group.

Discussion

There are four distinct advantages to stereotaxic surgery utilizing the technique described above:

1. It is an exceedingly accurate method. Destructive lesions of known size can be placed in a predetermined locus with a minimum of damage to surrounding structures. It has been argued by some that such accuracy is unnecessary in

most subcortical surgery presently being done. However, we feel that it is a definite advantage, both in terms of safety to the patient and to interpretation of the altered physiology. This is especially true of thalamic lesions where one is dealing with a group of nuclei with very diverse connections.

2. Before any destructive lesion is made, it is possible to carry out electrostimulation. This has the advantage of a physiologic demonstration of the position of the electrode.

3. There is precise control over the size of the destructive lesion made. As stated previously, one coagulation produces an ovoid area of destruction of approximately 4 x 2 mm. size. Six to twenty-two lesions have been produced in various patients, using as the end-point the desired clinical effect rather than an arbitrarily chosen number.

4. Reapplication of this stereo-encephalotome in a precisely identical position is a simple matter. Therefore, one is able to produce further lesions at intervals should this prove necessary. Re-application of the instrument has been necessary in a few patients at intervals up to six months, and it has been possible to do so without the need for repeat pneumoencephalography or any guesswork.

The question has arisen as to whether or not there is a somatotopic localization within the globus pallidus with respect to tremor and rigidity. Inasmuch as the stereotactic method lends itself to investigating such possibilities, an attempt was made to verify this hypothesis by varying the axis and direction of the lesions as they are progressively enlarged. At the present time, it is felt that somatotopic localization has not been delineated, and reduction of tremor or rigidity depends more upon the size of the lesion than its location within the nuclear mass under consideration.

Tremor and rigidity have been repeatedly named as the two symptoms in which we are primarily interested, and perhaps the impression has been given that they respond similarly to surgical destruction of the globus pallidus. This is not the case. Rigidity has been effectively reduced in every instance with relatively small lesions, and there has been little tendency for recurrence. On the other hand, tremor has not been significantly reduced in every instance, has required large lesions for effective alteration, and exhibits a distressing tendency to recur in the weeks and months following surgery.

TABLE IV. STIMULATION RESULTS

Disease	Structure	Response
Parkinsonism	Medial globus pallidus	Tremor exaggerated
	Lateral globus pallidus	None
	Internal capsule	Flexion of contralateral extremities
Athetosis	Medial globus pallidus	Movements mildly exaggerated
	Anterior V. L. nucleus	Movements markedly exaggerated
	Posterior V. L. nucleus	Dysesthesias in contralateral extremities
Centrencephalic seizures	N. centrum medianum	Arrest reaction
	N. ventralis anterior	None
Psychosis	Dorsomedial nucleus	Evoked potentials in frontal scalp leads
Hemiballismus	Medial globus pallidus	Movements mildly exaggerated

At the time of surgery, stimulation of the various subcortical masses has been carried out. In general, the results have been somewhat inconstant, and further work must be done before stimulation can be used as a reliable guide for the position of the electrode. The chart presented in Table 4 is then, merely a preliminary step in that direction.

The interpretation of the phenomena resulting from stimulation varies, of course, with the pathophysiologic aberrations present in each individual case. It is readily apparent from the data in Table IV that electrostimulation can be important in the study of a variety of disease states other than Parkinsonism.

Summary

A method for carrying out subcortical surgery has been described. Its application to the problem of Parkinson's disease has also been described. Experience with fourteen patients with Parkinson's disease has been discussed and a preliminary report on both the clinical and investigative aspects has been presented. It is felt that much more data must be accumulated in order to evaluate properly the place of surgery in diseases of abnormal movements.

Staphylococcic Sepsis in Hospitals

ARTHUR H. WELLS, M.D.
Duluth, Minnesota

From the Department of Pathology, St. Luke's Hospital, Duluth, Minnesota. Credit goes to Mirdza Peterson, B.A., M.T. (A.S.C.P.) for compiling the many bacteriology reports in this presentation.

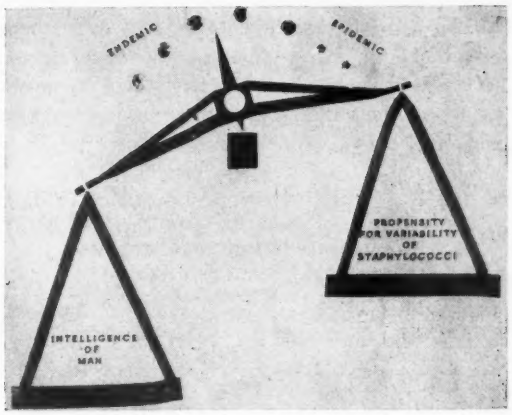

Fig. 1. The eternal struggle for life.

Presented at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota, May 27, 1959.

SEPSIS caused by staphylococci in hospitals has lately become the number one communicable disease of the country. Until medical research has found a permanent control for infections due to Micrococcus pyogenes, physicians are faced with what may be a long term continuous struggle with this most versatile and ubiquitous of all of man's parasites. This presentation will touch on some of the more important aspects of the epidemiology and control of staphylococci.

The osteomyelitis found in Egyptian mummies from 3000 B.C. is documentary evidence of the long duration of parasitism of man by these micrococci. The "laudable pus" of Paraselsus more than 500 years ago may mark the beginning of a feeling of familiarity for a seemingly innocuous infection; an attitude which persists today in the minds of some physicians. Lord Lister's monumental efforts in 1867 initiated an era of antisepsis, the technique of which has undergone considerable improvement. With the recognition of the serious nature of the problem with staphylococci, we have learned that our knowledge of antisepsis in hospitals is superficial and inadequate. About a decade ago with the discovery of penicillin there was a short lived period during which man had apparently gained control of this destructive, sinister, adversary only to find that, differing from most other bacteria, staphylococci have an ominous, genetic heritage; an ability to adapt themselves to many nocuous environmental exposures including those to transiently germicidal antibiotics. As a result of such exposure, the newly born strain of Micrococcus pyogenes frequently maintains all of the resistance to other antibiotics previously developed by its progenitors and at the same time may have gained or lost virulence for man. In essence, it is this innate adaptability of staphylococci (an evolutionary product of the eternal struggle of living things to survive) against which man's intelligence is now pitted (Fig. 1).

Natural Characteristics

Staphylococci can usually be recognized by their morphology because of their large size, coccus form, Gram-positive staining and the frequent occurrence in three dimensional clusters. Because of their universal distribution, they are relatively frequent contaminants of the bacteriologist's media. They have unusual resistance to heat and drying. The Micrococcus pyogenes variety aureus forms a yellow pigment, an important sign of pathogenicity.

Although not demonstrated by the usual methods of staining, it is sometimes said to have capsule formation. Practically all staphylococci are grown as facultative anaërobic organisms on a wide variety of simple artificial media.

TABLE I. SURVEY OF STAPHYLOCOCCUS AUREUS, COAGULASE POSITIVE PHAGE 80/81, INFECTIONS DURING SIX MONTHS
Number of Patients Surveyed—51

Skin infections	29
Pneumonia	6
Internal abcesses, lesions	6
Urinary infections	2
Eye, nose and throat infections	5
Dermatitis	1
Burns	1
Bacteremia	1

The ability of an isolated strain to coagulate plasma (coagulase test) is currently the one easily performed procedure most widely accepted as indicative of pathogenicity for man. It is conceivable that a few pathogenic strains may not have a positive coagulase test. Certainly, the loss of ability to form yellow pigment (staphylococcus albus) does not always indicate a lack of pathogenicity. Other signs of a pathogenetic nature of a strain are indicated by the presence of: hemolysins (destroys RBC's), exotoxin (necrosis of tissue), enterotoxin (food poisoning), leukocidin (kills WBC's), hyaluronidase (spreads infection), penicillinase (destroys penicillin), fibrinolysin (dissolves fibrin), protease (digests protein), lipase (fat splitting), desoxyribonuclease (nucleic protein), and others.

Few strains of the pathogen seem to be completely alike, consequently a means of identification of the various strains has become an important and difficult subject of research in bacteriology. At the present time, phage typing is generally considered the most practical way of classifying specific strains of staphylococci. This time consuming procedure helps determine whether a single strain is causing an epidemic or a high level of endemicity in a hospital or whether a heterogenous mixture of strains is found in a series of cultures of infections. Pure and mixed strain epidemiologic problems require entirely different interpretation as to the source of the bacteria. Certain phage types and particularly the 80-81 variety are now known for their widespread distribution and unusually high virulence. Like other characteristics of the staphylococci, the phage type may change in a given strain. This alteration does not appear to occur in the serologic methods of identifying staphylococcic strains; however, the latter are not yet considered practical for general usage.

Epidemiology

The futility currently being experienced in antibiotic therapeutic research relating to staphylococcus sepsis has accentuated the urgency of a need for knowledge pertaining to the ecologic aspects of this parasite, particularly those relating to epidemiology. A valid, rational and unifying concept of this science of the study of the etiology, frequency, distribution and other factors of infectious diseases was most comprehensively formulated by Theobald Smith (1934) in the Vannxem lectures delivered at Princeton. The gist of his contention was that all infections of man are the manifestations of a parasitism and that they express the eternal struggle for life by both the host and the parasite. This concept is eminently suited to the relationships of Homo sapiens and Micrococcus pyogenes variety aureus. One cannot escape the thought that the older of these two species with its innate versatilities at mutation and selective adaptation could become the most dreaded microparasite established in the orbit of man.

The importance of the role of *crowding of susceptibles* in inciting communicable diseases was apparently first emphasized by Sir James Simpson. More than a century later the staphylococci are found to be a menace primarily in our hospitals where large numbers of susceptibles are crowded, infections are abundant, 20 to 60 per cent of the personnel are chronic ambulatory carriers, and the chances of *cross contaminations* between the three groups are numerous. Our recent studies (Table I) seem to indicate a decided spread of the antibiotic resistant, phage type 80-81 staphylococci to the population outside of the hospital where approximately 50 per cent of these infections had their origin. Where this will end is difficult to predict.

The coagulase positive (virulent) strains of staphylococci are *propagated* in the sites of infections, on mucous membranes of the nose and throat of carriers, in intestinal tracts particularly of infants, about the umbilical cord in the newborn, and occasionally on areas of the skin such as in the groin of some individuals. Domestic animals harbor the organism. Nearly all other sources of staphylococci represent indirect reservoirs or vectors for the bacteria which outside of the sites of proliferation soon become an almost spore-like, dormant form of the organism. The great majority

room environment by patients with open infections such as those of the skin, pneumonia, empyema, sinusitis, bronchitis, entero-colitis, and certain patients with tracheotomy and urinary incontinence has been demonstrated to take place in a matter of a few hours. This added to the resistance of staphylococci to drying, heat, and chemicals permits the organism to float about on dust particles and fomites, to the myriads of resting places in the recesses of the hospital awaiting a more favorable environment in the fluids of man to again propagate a species possibly even better endowed to care for itself at man's expense.

The staphylococcus infection is *endemic* in all modern general hospitals. Sporadic major *epidemics* of a progressive type have occurred in and even closed large institutions at scattered points in the United States. The fact that 20 to 60 per cent of the personnel of hospitals are *ambulatory carriers* in close and frequent contact with patients is basic. Nursery epidemics generally follow a pattern. A virulent type staphylococcus is introduced into a nursery. It readily colonizes nasal passages of newborn infants and is passed from the older carrier problem in this situation is the basic reason for the epidemic and when it is controlled the epidemic will stop.

The *virulence* of staphylococci is such that the usual experience is that a high nasal carrier rate exists and many minor skin infections are to be expected, punctuated by occasional very serious or fatal infections, all due to the same strain of staphylococci. Clinical experience suggests that infections contacted directly from other infections are, generally speaking, more likely and more serious than those in which the bacteria are from carriers, and the latter infections appear to be more likely and more serious than those caused by the more dormant organisms on dried dust particles from the inanimate reservoirs of the hospital. The great bulk of the infections in our hospital experience are the minor skin infections (Table II) where the organism is increasing in great numbers and being on a surface can be easily disseminated. In one of our surveys, the nasal carriers had a high per cent of antibiotic resistant, virulent organisms (Table III). The low virulence of staphylococci might be compared with the high mortality result-

ing in other contagious diseases, such as cholera, where the organism frequently quickly kills its victim and thus the propagator and disseminator are buried along with his cargo of deadly vibrio to stop

itating diseases. It may be that the resistance of many of these patients would eventually fall to a point where many bacteria ordinarily considered harmless might invade and kill. This group of in-

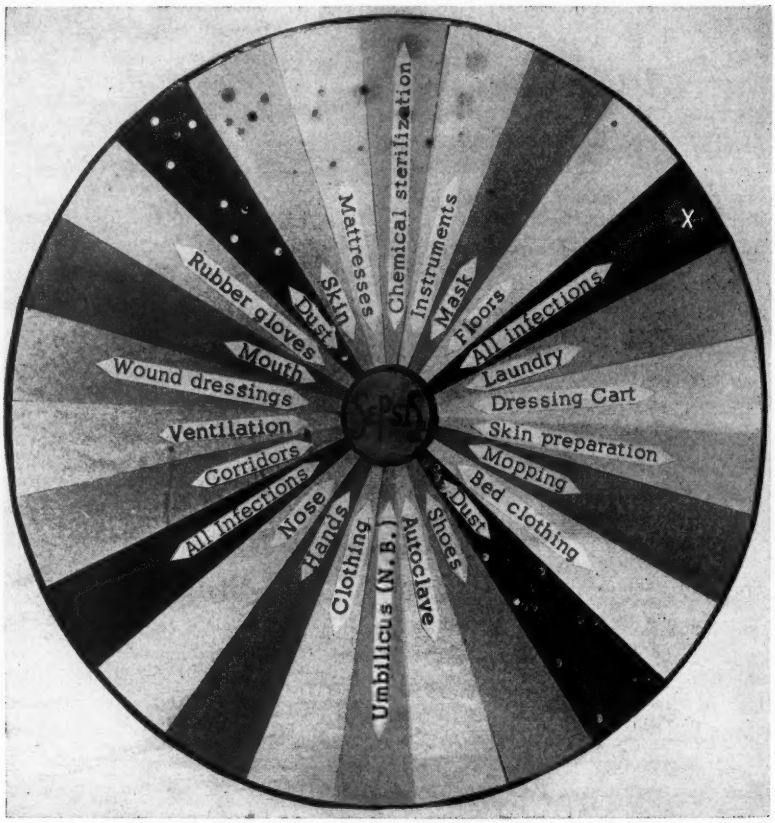

Fig. 2. The Roulette universe of staphylococci. X indicates the staphylococcus.

the sequence promoting a spread of the parasite. In the entire world, cholera is now endemic only in certain overly populated, unsanitary areas of India.

The *individual susceptibility* of man varies greatly. Infants are highly susceptible but are said to develop a resistance equivilant to that of an adult during the first year of life. This resistance sometimes appears to be lost in the waning years of old age.

The groups of patients most frequently involved currently in staphylococcus infections are: (1) those with surgical wounds and otherwise broken dermal barriers; (2) newborn babies, (3) nursing mothers, (4) premature infants and (5) a large heterogenous group of patients with lowered resistance, especially the elderly with chronic debil-

dividuals with increased susceptibility includes patients with diabetes mellitus, malignancy and many other similar chronic wasting diseases, also those with chronic alcoholism, bed sores and other breaks in the skin such as dermatitis, burns, frostbites, indwelling catheters and skin "cutdowns." Included also are influenza, coma, vomiting, agranulocytosis, starvation, prematurity, toxemias, allergies, iatrogenesis including heavy sedation, adrenal steroids and other hormones and nitrogen mustards, folic acid antagonists and other neutropenia producing drugs. Infections by staphylococci do not produce a measurable *conferred immunity* as in typhoid fever, thus a continuous site for propagation is favored in the majority of mankind. The rare occurrence of a fulminant fatal septicemia

from a furuncle in an apparently robust, healthy individual is a well known phenomena.

The *community susceptibility* will vary with the distribution of the patient population of a given hospital. Today much larger numbers of elderly patients are admitted to general hospitals with their chronic ailments and lowered resistance. This shift in hospital population is one of the important factors of the increased *incidence* of staphylococcus infections in the nosocomial environment.

The inter-relationship of *dissemination* and *propagation* in a hospital is diagramatically and incompletely illustrated in "The Roulette Universe of Staphylococci" (Fig. 2). The greater the staphylococcus endemic level in a hospital the greater the *chance* of sepsis. An average patient entering an average general hospital has approximately a 20 to 50 per cent chance of having his nasal mucous membranes colonized by antibiotic resistant, virulent staphylococci in from forty-eight to seventy-two hours. If the patient has a large break in his skin barrier or has lowered resistance to infection because of a chronic debilitating disease or some iatrogenic alteration, his chances of contracting a serious staphylococcus infection are greatly enhanced.

Control

Until some anti-infectious agent is discovered which will permanently control man's staphylococcic parasites, these micro-organisms must be held in abeyance by a carefully planned and directed multiphased program. Since large segments of the hospital lay personnel are involved and much inspired direction and detailed supervision is necessary, physicians have combined with the hospital administration and departmental supervisors to form the Hospital Infection Committee. There follows a suggested mostly self-explanatory outline of the composition and responsibilities of this committee.

Hospital Infection Committee

I. Composition
- A. Medical staff
- B. Administrative department
- C. Nursing department
- D. Housekeeping department
- E. Laboratory

II. Responsibilities
- A. Surveillance
  - (1) routine culture of all infections
  - (2) measure endemic status
    - (a) surgical procedures
    - (b) housekeeping procedures
    - (c) carrier status of personnel and staff
    - (d) ventilation hygiene
    - (e) special problem areas
  - (3) maintain "outcome" records
    - (a) surgical wounds
    - (b) all other infections
    - (c) autopsy infections
    - (d) newborn follow-up (8 weeks)
    - (e) inanimate environment
  - (4) formal peroidic reports
    - (a) medical staff
    - (b) personnel
- B. Control
  - (1) evaluation of all phases
  - (2) recommend changes (to staff and administration)
  - (3) initiate changes
  - (4) institute epidemic controls
  - (5) assign personal responsibilities
  - (6) surgical dressing cart or tray usage
  - (7) isolation rules
  - (8) segregation of departments
  - (9) segregation of patients
  - (10) infections of personnel
  - (11) admission policy
    - (a) infected patients
    - (b) unusually susceptible patients
  - (12) inter-hospital relations
  - (13) charges for "demand" cultures
  - (14) charges for "enforced" layoff
- C. Education
  - (1) hospital personnel
  - (2) all professional groups
  - (3) import "expert" speakers
- D. Measure effectiveness
  - (1) comparative records
    - (a) endemic status—A (3)
    - (b) all infections—A (3)
- E. Research

The committee is organized under the control of the medical staff with complete co-operation of the hospital administration, nursing staff, housekeeper and pathologist. Nothing will cast off the veil of uncertainty concerning the existence of the presence of a staphylococcus problem in a hospital as quickly as unnecessary deaths from the disease. A medical staff report of necropsy studies followed in quick order by imported authoritative medical speakers, then by reports of a bacteriologic assessment of the magnitude of the local problem, including cultures from inanimate objects, "fallout" cultures, nasal carrier frequency, and staphylococcic infections of all types. A critical study of the numerous technical nosocomial procedures involved by an "out of town" authority will hasten a badly needed knowledge of the lay personnel. Once the medical staff has visualized the long term omnipresent danger to which their patients are exposed, there should exist a unified effort necessary for success in our independent methods of private practice.

The six widely used approaches to the partial control of the hospital sepsis problem include: (1) the establishment of mutually beneficial rules of hospital medical practice; (2) modernization of housekeeping procedures; (3) improvement of numerous technical paramedical practices; (4)

maintenance of epidemiologic records; (5) publication of periodic reports, and; (6) educational experiences for both lay and professional groups. These should maintain the continuous self appraisal and interest necessary for success in this long term project.

TABLE IV. "FALLOUT" DURING OPERATIONS
(Blood Agar Plate)

Surgical Procedure	Number of Cases	Total Colony Count/Plate Max.—Min.	Total Staph. Aureus Colonies/Plate Max.—Min.	Total Other Bacteria Colonies/Plate Max.—Min.
Appendectomy	9	62-6	11-0 (5 neg.)	53-5
Cholecystectomy	10	48-5	10-0 (6 neg.)	40-5
Herniorrhaphy	10	41-1	8-0 (3 neg.)	40-1

Possibly the greatest problems of the Hospital Infection Committee in a private institution are concerned with the standardization and enforcement of rules on the practice of medicine. A limitation of the use of specific antibiotics to preserve their usefulness for the more seriously infected patients in a given hospital environment may easily result in a variation of opinions, in spite of the acknowledged value of the ruling. An added hospitalization expense is incurred by every strict isolation ruling, yet, this practice for the "open" types of staphylococcus infections must be mandatory. Possibly some physicians might be inclined to overlook minor stitch infections in their patients whereas a good nurse, so ordered, will see to it that cultures are taken and the infection recorded. When dressing wounds, "non-touch" techniques alone are not as good as when combined with the more time consuming use of sterile rubber gloves, masks, and the aseptic disposal and sterilization methods for contaminated objects. Restrictions of physicians with staphylococcus infections is a problem. In the operating rooms and nursery, it may be necessary to "lay off" the nonprofessional and nursing personnel with pay to protect the patients from open infection in these ambulatory personnel.

A critical review of surgical operating room techniques has resulted in a new set of rules of procedures. The only pathway from the contaminated hospital environment to the operating room leads through a locker room where there is a complete change into sterile clothes with an intervening shower. Sterile covers for the usually badly contaminated operating room shoes is a must. Any professional visitors go through the same routine. Movement through doors and about the operating room is restricted. Minimum ten-minute hand scrubs and hourly exchanges of the best available masks are mandatory. A more detailed pre-entrance preparation of patients with a complete shedding of all contaminated covers and clothes and a skin preparation designed to penetrate hair follicles is rigidly followed. Alkaline soaps are neutralized by acid detergents and alcohol neutralizes the beneficial action of creosol products, therefore a proper selection of cleansing and antiseptic agents is necessary. A routine "error check" conducted by the head nurse at the end of each operation keeps everyone on the alert for punctured gloves and other slips in technique. "Fallout" cultures (Table IV) should be on a routine periodic basis. The postoperative sterilization of the room and instruments follows a well-established ritual. Culture controls of autoclaves must be routine. Even a late admission of the patient to the hospital to prevent nasal colonization prior to the operation is advocated by some surgeons.

Cleanliness alone is no longer adequate in the numerous housekeeping activities about the hospital. Controlled, germicidal antisepsis is a necessity. The usual wet floor mopping of yesterday can be one of the greatest disseminators of staphylococci by way of the largest of all reservoirs of these organisms, the floor. The extra cost of a germicide such as Amphyl, Wescodyne, O'Syl, Tergisyl, and Permachem and others when added to the cost of floor mopping, wiping of the walls and furniture of the contaminated sick room are small in comparison to the cost of the staphylococcus complications in the sick. The necessity and means of sterilization of contaminated blankets, mattresses and other bed clothing has been repeatedly stressed along with the use of labeled, individual impervious bags for transporting articles through hospital corridors and laundry chutes. The exchange of empty for filled waste baskets and garbage cans prevents local contamination.

The most important inanimate vector of staphylococci is dust. Those who care for the sick must understand that any activities which stir up or make dust, spread staphylococci. The unnecessary shaking of contaminated bed clothing is as filthy as spitting on the floor. Epidermis and clothing particles fall from the body and clothing and currents of air pick up fallen particles as the result of walking across an operating room floor. Air-conditioning apparatus once designed primarily for heat and humidity control must be altered to include better filters for eliminating bacteria. The air-conditioning pressures must cause a steady flow of air from the inside out, in nurseries and operating rooms.

The danger of the "fallout" from the ambulatory necessitates isolation of the more susceptible patients and segregation of whole sections of the hospital including the nursery and operating rooms and a separate isolation department for the patients with staphylococcus infections. The architecture and building materials of new hospitals must be altered to meet this new challenge of human security.

More adequate segregation of the newborn from each other and from the rest of the hospital has become a necessity. If individual cubicles with positive pressure air-conditioning is not possible, a division of the babies according to dates of birth so that older infants do not contaminate the more recently born may help. Complete isolation of the baby in the mother's room has been a solution. Others have advocated routine use of nasal jells with antibiotics. The vulnerable umbilical cord must be protected with a satisfactory germicide. The stools must be considered heavily contaminated. Follow-up records of discharged newborns for at least eight weeks are essential for the proper protection of a nursery. Mothers should not nurse infants whose nasal mucous membranes are colonized by the 80-81 phage type staphylococci.

The Hospital Infection Committee must know the epidemiologic status in all sections at all times.

Among its records are those of surgical wound infections (Tables V and VI). Comparative antibiotic sensitivity studies on the organisms isolated from hospitalized patients are important (Table VII). All infections found at necropsies should be studied as to etiology, frequency and types of diseases (Tables VIII and IX). Accumulated records of all hospital infections as to etiology and source (Fig. 3) are essential. Spot checking of numerous likely areas of contamination is a necessary function of the bacteriologist. It is only through the comparative study of these records that the medical staff can know what is or is about to happen to their patients in this struggle with our ever present staphylococci and enterobacilli.

Conclusions

Staphylococci are the prolific, rugged, and versatile opportunists among the bacteria parasitizing man. With their ancestorial roots growing deep in nature (saprophytes), with large numbers of progeny produced in many readily available ambulatory carriers and in a wide variety of infections easily accessible to the surface of the body and with a most unique ability to survive natural and man made environmental barriers, they represent a most formidable foe. Until man has found a successful antibacterial control of the staphylococcus, his best intelligent efforts will be matched against the ominous, innate adaptability of this organism which has made it the most important communicable disease of our time. A critical study and control of numerous details pertaining to medical practice, housekeeping procedures, paramedical techniques and the development, maintenance and publication of epidemiologic records have become a necessary function of every hospital medical staff.

Management of Urinary Stress Incontinence

Because of its extensive social and psychologic implications, the problem of urinary stress incontinence is of utmost importance to the unfortunate women so afflicted. This article is a general review of the surgical management of this distressing condition.

RICHARD E. SYMMONDS, M.D.
Rochester, Minnesota

From The Section of Surgery, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

THE hundreds of operative technics devised to cure stress incontinence of urine not only indicate that no single operative or medical method of management of the condition has been completely satisfactory but also indicate that what is known of vesical physiology and the pathophysiology of stress incontinence is poorly understood.

Cystographic studies of the incontinent patient by various techniques, although they represent only static, single phases of the rapid complex mechanism of micturition, have demonstrated various anatomic displacements such as descent of the vesical base and the urethra, funneling of the bladder neck, loss of the posterior urehtrovesical angle, and urethral shortening. Each of these anatomic changes has been considered at one time or another to be the primary cause of stress incontinence. We now know, however, that only about 85 per cent of the patients with stress incontinence demonstrate such displacements of the vesical neck and that, conversely, many patients with considerable prolapse, including some with cystourethrocele, are entirely continent. Rapid serial radiography, as devised by Ardran, and others,[1] the cinefluorographic studies of Lund and associates,[2] and the studies of Youssef and Mahfouz[3] and also of Lapides[4] and co-workers[5] have clarified our thinking considerably.

The investigations of Lapides,[4,5] which appear to have been largely overlooked in gynecologic circles, have been particularly noteworthy with respect to normal vesical physiology and sphincteric function. As a result of these studies and others mentioned above, one can state that the primary deficit common to all patients with stress incontinence of urine is relaxation of the internal involuntary vesical sphincter. Irrespective of the presence or the absence of the posterior urethrovesical angle, displacement of the vesical neck, and cystourethrocele, which are merely manifestations of prolapse (Youssef and Mahfouz[3]), the proximal urethra (that is, the internal sphincter) is relaxed and atonic in all patients with this form of incontinence. The role of the voluntary or external sphincteric mechanism, although important, is entirely secondary and compensatory. It is called into play when the resistance provided by the internal sphincter is inadequate and has been overcome by increased intravesical pressure. Thus understood, severe stress incontinence necessarily implies some attenuation of the external sphincter in addition to that of the internal sphincter. This is best indicated clinically by the ability of perineal exercises (Kegel[6]) to restore continence to some women even though these exercises of the voluntary perineal muscles could have little effect on the atonic smooth muscle of the involuntary internal sphincter.

Despite numerous anatomic descriptions of the internal sphincter, its exact location and function have remained rather obscure. For practical purposes, as Lapides[4] remarked, the terms internal sphincter, female urethra, and bladder neck can be considered synonymous. The smooth muscle of the urethra is continuous with that of the bladder, has a nerve supply derived from the same source, and is developed from the same embryologic origin. The internal sphincter therefore consists of

a tube composed of smooth muscle that functionally is part of the bladder proper. The formerly held concept of reciprocal innervation and function of the detrusor urinae and proximal urethra (internal sphincter) appears to be erroneous.

Lapides[4] has pointed out that the resistance to flow in a tube such as the urethra depends upon the inherent tension in the walls, the length of the tube, and the radius of its lumen. That this principle can be applied to the urethra and the subject of stress incontinence is suggested by a number of observations.

1. The continent patient has an elongated, high-placed urethra with good tension in its walls (an inherent property of the smooth muscle of which it is composed); and when this tension is adequate the urethral lumen has a radius of zero.

2. The incontinent patient has a shortened urethra with proximal dilatation, funneling, posterior flattening, and with little inherent tension in its walls. These characteristics may be of unknown cause, as in the incontinent nulliparous or even virginal patient; or they may be secondary results of childbirth injuries, postoperative scarring and fixation, postmenopausal attenuation of the supporting tissues, or other etiologic factors.

3. When the urethra has been excised or lost for one reason or another and an artificial urethra is constructed from a bladder flap of smooth muscle, the patient is continent of urine, provided the urethral tube constructed is 3 or more cm. in length. A tube of this length, although devoid of extrinsic innervation, has sufficient inherent tension in its walls to maintain continence.

4. Surgical experience also leads one to agree with this concept of internal sphincter or urethral function that is dependent upon the length, diameter, and tension of the urethral walls. To be successful the operative technique must result in elongation and elevation of the urethra and in some narrowing of the urethra lumen. Whether this is accomplished by stretching the urethra from above—suprapubically (as described by Marshall and others[7]), from below by periurethral fixation and urethral advancement (Berkow[8]), by vaginal elevation and constriction of the urethrovesical structures (Kelly and Dumm,[9] Kennedy[10]), or by a combined abdominovaginal technique (Ball[11]) is of little importance so long as the afore-said objectives are achieved.

The surgical treatment of the incontinent patient should be directed toward permanent correction with a single operation of as many of the urethrovesical abnormalities as possible. Operations must be individualized. The extent of the operation should be determined primarily by the degree of incontinence and the degree of urethrovaginal prolapse and displacement of the bladder neck. Additional consideration should be given to such factors as failure of previous surgical procedures, vaginal stenosis, urethral shortening, scarring and fixation, and the presence of obesity, chronic bronchitis, asthma, and so on. To use a single operation for all patients with stress incontinence regardless of these factors, as many surgeons formerly did, is obsolete. Equally outmoded is the thought that, "If this operation doesn't work, we then can do a Marshall or sling operation; and if that doesn't work we can do something else—or refer the patient elsewhere." The most favorable opportunity to cure the patient exists at the time of the primary operation.

The patient with slight incontinence, who might be a suitable candidate for a simple Kelly operation, frequently can be managed equally well by nonsurgical measures that may include exercises, estrogens (for individuals whose stress incontinence first appears in postmenopausal years), and the eradication of mild inflammatory processes (cicatricial and granular urethritis, trigonitis) which may precipitate or aggravate mild incontinence. Experience at this clinic indicates that the apparent initial rate of cure of 85 or 90 per cent obtained with the Kelly operation gradually deteriorates to between 50 and 60 per cent as the years pass. For this reason I infrequently perform the Kelly[9] operation alone, although its desirable features are incorporated into various other techniques.

At present the Kennedy[10] operation, combined with vaginal hysterectomy or another operation for prolapse, is the procedure perhaps most often used for moderate degrees of urinary stress incontinence. Although it cures approximately 85 per cent of the incontinent patients initially, approximately 25 per cent of the patients subjected to a Kennedy repair primarily for stress incontinence eventually require additional treatment. For this reason my colleagues and I have tended in recent years to perform more extensive surgery at the time of the primary operation, especially for those patients with severe or recurrent incontinence, the obese, those with bronchitis and so on,

who we know constitute the majority of the operative failures.

In cases of moderate to marked incontinence, I frequently resort to some supplementary procedures to provide increased elevation and more permanent support for the vesical neck.[12] At one time, I used the Ingelman-Sundberg technic,[13] which consists of—in addition to Kennedy plication—mobilizing the anterior half of the pubococcygeus muscle on each side and bringing these muscle slings under the neck of the bladder for additional support. Although this works satisfactorily, at times considerable bleeding may be encountered laterally. For that reason, I now use the technique described by Pacey,[14] which consists of passing sutures through the anterior portion of each pubococcygeus muscle and approximating these tissues beneath the bladder neck without severing them laterally. In addition, the medial fibers of the bulbocavernosus muscle can be approximated to provide further support and to advance the urethral meatus somewhat. If the pubococcygeal portions of the levator muscles are brought together anteriorly, as Pacey[14] suggested, one must be extremely careful not to approximate the levators too high in the posterior colpoperineorrhaphy, for otherwise the vagina will be unduly constricted.

If one vaginal plastic operation has failed to cure a patient, the chance that a second operation of the same type will do so is slight. As a rule, more extensive surgery is required. I consider the Marshall-Marchetti[7] operation (urethrovesical suspension) to be the operative procedure of choice for most patients with recurrent forms of urinary stress incontinence. If the patient has recurrent stress incontinence associated with some recurrence of a cystourethrocele or a short, fixed urethra, a combined operative procedure may be done to insure success. Frequently this consists of a Kennedy plication, with or without approximation of the pubococcygeal muscles, followed by the Marshall-Marchetti operation. If the urethra is considerably shortened and fixed by scar tissue, it sometimes is best merely to mobilize it vaginally without any attempt at plication from below. This facilitates the subsequent elevation and elongation of the urethra by the Marshall-Marchetti sutures.

Occasionally the Marshall-Marchetti operation is indicated as a primary operative procedure: (1) for patients who have severe urinary incontinence associated with vaginal stenosis—or at least with little evidence of cystourethrocele; (2) for patients in whom the presence of other pelvic pathology indicates the necessity for a suprapubic incision; (3) for patients with a congenitally short, dilated urethra; (4) as part of a combined abdominovaginal operation in some cases of severe urinary stress incontinence. From experience here, the Marshall-Marchetti operation, with or without supplemental vaginal repair, may be expected to cure the incontinence in about 85 per cent of cases, regardless of whether the operation is primary or secondary.[15] This operation entails much less technical difficulty and considerably fewer complications than do the various sling techniques. The period of hospitalization has averaged twelve days after the Marshall-Marchetti operation and almost twenty-three days after Millen-Read sling operations. The increase in the latter figure is due almost entirely to prolonged urinary retention, which has not been a problem following urethrovesical suspension. The Marshall-Marchetti operation has almost supplanted other suprapubic operative techniques in our use.

Perhaps there is a place—even though somewhat limited—for the fascial sling operation. Strangely, some of the patients who have a poor result from the Marshall-Marchetti procedure are benefited by a sling; conversely, in a number of cases in which sling techniques failed, cure was effected subsequently by the Marshall operation. The patient with recurrent stress incontinence and asthma, chronic bronchitis, or bronchiectasis also might be considered a suitable candidate for a fascial sling operation.

In concluding it may be said that a multitude of operative procedures are available for treatment of stress incontinence, any one of which will provide good results if the period of follow-up is relatively short. With passage of time and increase in the patient's age, the rate of cure obtained with many techniques steadily diminishes. I wish to reemphasize and encourage the present trend throughout the country to extend the initial operative procedure as necessary in the individual case to achieve the desired operative objectives of urethral elevation, elongation, and diminution of caliber. One should not try to fit the patient to a pet operative procedure. In many cases a combination of several vaginal or even abdominovaginal techniques may be necessary to obtain a cure that will stand the test of time.

Bronchial Closure with Tantalum Wire Sutures

The author presents his experience utilizing tantalum wire sutures for closure of the bronchial stump during pulmonary resection. The experience of others with various types sutures is also given. Tantalum wire and catgut cause the lowest incidence of suture granulomas and dehiscence or blow-out of the bronchial stump. The monofilament wire sutures indicate the site of amputation of the bronchus on postoperative x-ray examination.

JEROME T. GRISMER, M.D.
Minneapolis, Minnesota

Dr. Grismer serves the Staff in Thoracic Surgery at Mt. Sinai Hospital, Minneapolis, and Methodist Hospital, Minneapolis.

THE HEALING of bronchial stumps is one of the major factors influencing the results of pulmonary surgery.[1] Defective healing can be associated with two degrees of morbidity. The major complication is stump dehiscence (bronchopleural fistula). A more minor alteration is suture granuloma.

Dehiscence

Bronchial stump dehiscence is a postoperative catastrophe which may be difficult or impossible to control. The significant mortality or prolonged morbidity make this a dreaded entity to the patient and the thoracic surgeon. Dehiscence usually results from either uncontrolled infection, residual neoplasm, or technical errors in closure of the bronchial amputation.

It is axiomatic that a diseased bronchus heals poorly, if at all. Infection, whether extra-bronchial, endobronchial or intrabronchial, retards secure fibrosis with the resultant danger of "blow-out" from the intrabronchial pressure. Experience has shown that the type of suture used to close the bronchus is not the important factor in the prevention of such ruptures.[2] The vital factor is control of the infection.[3] Similarly, if a bronchial stump is involved with neoplasm, early or late breakdown and fistula result despite all efforts to avoid this.[4]

Technical errors are the outgrowth of carelessness or inexperience. Improper maneuvers on the stump include: (1) lack of coverage; (2) devitalization by high ligation of the bronchial arteries or skeletonization; (3) residual excess length with resultant stagnation of secretions; (4) the non-discriminating placement of suture material.

Suture Granuloma

This is an iatrogenic illness of known etiology. The usual features in a post-resection patient are an aggravating cough, recurrent hemoptysis, and often the production of the offending agent. Although usually more aggravating than dangerous, such granulomas are extremely serious at the site of tracheoplasties or bronchoplasties because of airway obstruction.[1,5] Another serious hazard is the nidus formation of active tuberculosis about infected sutures. Until the sutures are either spontaneously ejected or removed endoscopically or by thoracotomy, the symptoms persist.

Tantalum Wire Closure

To decrease the number of these two complica-

tions, every thoracic surgeon must carefully evaluate his method and material for bronchial closure. Therefore, I would like to present my experience in the use of monofilament 4-0 tantalum wire on atraumatic curved round needles (Ethicon) for closing the bronchial stump.

TABLE I. TYPES OF SURGERY

Neoplastic and Non-neoplastic Diseases	
Pneumonectomies	9
Lobectomies	28
Segmental Resections	63

One hundred consecutive pulmonary resections from July, 1955, to July, 1958, have been analyzed. Table I lists the types of surgery. Table II presents the complications postoperatively. Thus far there has been no dehiscence of the stumps or clinical symptoms of suture granuloma.

The method of bronchial closure has been the same in all cases. A short healthy stump (5 mm.) without injury to the bronchial vessels is developed. The proximal bronchus is occluded cartilagenous to membraneous portion by a Pott's non-crushing bronchus clamp. A single row of interrupted end over sutures 2-3 mm. apart and 2-3 mm. deep is placed beneath the clamp. Traction of these sutures effectively approximates the bronchial margins as the Pott's clamp is removed. Each suture is tied and cut "on the knot." After a negative-water seal test, the stump is covered by any convenient mediastinal tissue with a 4-0 chromic catgut suture.

The wire suture is used for all except the very distal bronchi; for closure of these, 5-0 arterial silk is used.

Discussion

The normal tracheobronchial tree is "sterile" of pathogens. However, after thoracotomy (or even abdominal surgery), the normal secretions stagnate in the finer ramifications of the bronchopulmonary tree because of splinting, narcotics, anesthesia, loss of cough reflex, etc. During the immediate postoperative period, no matter how "clean" the bronchi preoperatively, most patients raise grey to yellow sputum. This type of sputum often cultures hospital-strain resistant pathogenic micrococci, even though the patients have been hospitalized only twenty-four to forty-eight hours. As the patient re-institutes adequate ventilation and coughing, this sputum rapidly becomes clear, mucoid and eventually disappears. It is not difficult to visualize this intrabronchial flora gaining access to the bronchial stump and instigating a low grade or virulent infection about the sutures.

The ideal sutures for bronchial closure would therefore have the following characteristics: (1) have adequate prolonged tensile strength compatible with smallest bulk; (2) be relatively unaffected by surrounding infection; (3) have minimum reaction to host tissues; (4) have minimum tendency for knots to loosen; (5) be easily handled by the surgeon.[6]

TABLE II. POSTOPERATIVE COMPLICATIONS

Mortality and Morbidity

Death—1. Seventy-two-year-old Japanese man succumbed on the fifth postoperative day after resection right middle lobe for carcinoma. Autopsy revealed intact RML stump and massive CVA.

Complications—16 bronchopleural fistula (BPF)*

1. 2 BPF—following lobectomies for tuberculosis. Good result from closed chest tube suction. Air leak probably from alveolii.
2. 14 BPF—after segment resections for tuberculosis:
   (a) 9 BPF treated successfully by closed chest tube suction.
   (b) 2 BPF were alveolar air leaks because of inadequate lung volume to chest cavity (space problem). Successfully treated by apical tailoring thoracoplasty and closed chest tube suction.
   (c) 3 BPF required open thoracotomy and suturing of segmental plane alveolar air leaks. No leakage at bronchial stumps. Resulting clinical course uncomplicated.
3. No incidence of suture granulomas clinically: Majority of cases *not* bronchoscoped after surgery.

*The term "bronchopleural fistula" signifies a post-operative air leak from any source in the residual lung or bronchi.

The more common sutures utilized are the non-absorbable types (wire, silk, cotton, synthetic threads) and the absorbable materials (catgut).

Tantalum is an exceptionally good suture material.[7] Tissue response is minimal compared to the intense reaction to catgut. Surrounding infection is well tolerated, often without extrusion of the tantalum because of the metal's non-participation as a foreign body. This is not true of silk, and catgut is rapidly dissolved in the same circumstances. Tantalum is as strong as other materials and is more malleable than stainless steel. Although fibrosis is more marked, foreign body granulomas to tantalum are very rare and not emphasized by workers in experimental suture material studies. The cost is less than equal amounts of silk or catgut.

Other advantages of the monofilament tantalum wire in pulmonary surgery are absence of wick quality and visualization by x-ray. This pinpoints the site of stump amputation and therefore, stump length. Furthermore, if x-rays reveal dislodgment of a suture, the surgeon is alerted to a possible "blow-out."

The most serious disadvantage of wire suture is its rigid nature. It is a distinct possibility that erosion of a hilar vessel might occur. Dr. Conklin mentions this complication as having happened,

although not in his series. I have had no personal difficulties of this nature.

After several unsatisfactory experiences with silk suture granulomas, I found it easy to imitate the suture for bronchial closure of Dr. William Conklin of Portland, Oregon. Since 1943, Dr. Conklin and his associates have used the monofilament tantalum wire suture.[8] Conservatively estimated, they have performed 2,000 pulmonary resections.[8] The majority of these were for tuberculosis. There have been a number of stump ruptures, but Dr. Conklin believes that the basic problem has been uncontrolled infection or residual neoplasm rather than failure of the suture material. There have been no clinical cases of suture granulomas and therefore no need to endoscopically remove sutures.

Dr. Bjork,[9] after extensive experience with stainless steel wire, silk, and catgut sutures in resections for tuberculosis, now champions the catgut bronchial closure as best. Catgut sutures entirely avoid the problem of suture granulomas and the incidence of stump rupture is not increased (Table III). Bjork also thinks that the use of stainless steel wire results in as many granulomas as silk, and wire is more difficult to remove. Others[10] have also favored catgut as the best suture for bronchial closure.

Large series of pulmonary resections are presented in which silk or wire were used for bronchial closure. These authors do *not* mention the incidence of suture granulomas in their review. The occurrence of bronchopleural fistula is not unusual.[11,12,13,14,15] (For a more complete presentation of complication incidence, see Table IV).

Experimentally, rupture of the stump (independent of infection) is not influenced by the suture material but rather by the type of closure.[2] The end-over type closure with interrupted sutures reinforced by "pleuralization" is the strongest. Suture granulomas are definitely related to the material used and the method of placement. Monofilament tantalum wire and catgut are the least conducive to this complication.

TABLE III. INCIDENCE OF BRONCOPLEURAL FISTULA AND SUTURE GRANULOMA[9]

Pneumonectomies—Tuberculosis

Group I: Crafoord invagination technique but suture not described (probably silk).
Group II: Stainless steel wire *or* silk sutures used.
Group III: Chromic catgut *plus* silk sutures used.
Group IV: Chromic catgut sutures *only* used.

Group	Total Cases	BPF	Suture G
I†	65	1	4
II†	42	1	8

PN—Pneumonectomy
LB—Lobectomy
SR—Segmental resection
BPF—Bronchospleural fistula
D-BPF—Death directly resulting
SG—Suture granuloma

*Emphasizes silk is not to penetrate mucosa.
**Stainless steel monofilament wire with swedged needle.
†Used silk and wire. Two BPF were in silk closure. Also quotes world literature 7,750 resections, 520 BPF's (6.7%).
‡T-wire = Tantalum.

Summary

Suture material used for bronchial closure does not significantly influence the incidence of bronchopleural fistula. This complication results from residual neoplasm or uncontrolled infection in the bronchial stump. The incidence of suture granuloma in the bronchial stump is directly related to the type of suture used. Catgut and monofilament tantalum wire are the least conducive to granuloma.

An Evaluation of the By-pass Graft in Arteriosclerotic Occlusive Disease of the Femoral Artery

EUGENE F. BERNSTEIN, M.D.
JERRY C. ROSENBERG, M.D.
ALAN P. THAL, M.D.
Minneapolis, Minnesota

Dr. Bernstein is Postdoctoral Research Fellow, National Heart Institute, United States Public Health Service.
Dr. Rosenberg is Clinical Fellow, American Cancer Society.
Dr. Thal is Established Investigator, American Heart Association.
From the Department of Surgery, University of Minnesota Hospitals, Minneapolis, Minnesota.

DURING the past ten years, a number of factors have combined to make arteriosclerotic occlusive disease of the lower extremities a commonly diagnosed and, because it is now treatable, important surgical problem. The development of simple and efficient diagnostic methods, adequate surgical techniques, prosthetic devices which are inexpensive and plentiful, and an increased knowledge of the occlusive arteriosclerotic process in general and its segmental distribution in some patients, all have been basic to this progress. In addition, the gradually increasing number of aged people has been accompanied by an increase in the number of patients with advanced arteriosclerotic disease. It is likely that the problem will continue to be numerically important.

Because of the clinical, pathological and surgical considerations which are peculiar to this area, it is logical to consider patients with femoral arterial occlusions as a separate group. The patient with femoral arterial occlusion is more likely to have severe distal arterial disease, and less likely to have developed adequate collateral circulation around the area of occlusion than the patient with aortic or iliac occlusion. In addition, since smaller vessels are involved, the surgical difficulties are greater, and increased likelihood of recurrent occlusion postoperatively results from a continuation of the arteriosclerotic process. For these reasons, the outlook for successful surgical treatment of the patient with femoral arterial occlusion perhaps should not be as optimistic as has previously been predicted.

The pioneering work in vascular surgery dates back to the experiments of Carrel.[1] In 1901, he performed end-to-end and end-to-side anastomoses using both fresh homografts and autografts. It was not, however, until 1951 that the first reports of clinical success with by-pass grafting procedures appeared. In that year, Kunlin[2] reported a series of seventeen patients in whom he performed a femoral by-pass procedure, using saphenous vein autografts in all but one case (in which an arterial homograft was used). Both resection with replacement and by-pass techniques were attempted in this country soon thereafter.

Crawford and DeBakey[3] reported forty patients on whom femoral by-pass procedures were performed utilizing arterial homografts; of these, thirty-seven, at least initially, were successful. However, less success was reported by Linton,[4] who, in comparing the resection and by-pass techniques, reported a 60 per cent failure rate in a group of twenty femoral arterial resections, while in a group of fifteen patients treated with the by-pass technique, he reported an 87 per cent success rate (with maximum follow-up of eight months).

The advantages of the by-pass method were well summarized by Linton and include: (1) preservation of collateral vessels; (2) less dissection; (3) an easier and larger anastomosis; (4) a greater likelihood of long-term patency. For these reasons, in many institutions, the by-pass has largely supplanted the resection in the treatment of patients with occlusions at the femoral level.

While optimistic reports of excellent results with both resectional and by-pass techniques began to appear in the literature in increasing numbers, the discouraging report of Hoye and Warren[5] in 1956, is of considerable significance. In their group of twenty-nine patients with femoral grafts, there was a 70 per cent failure rate, and this was approximately equally divided between the end-to-end and end-to-side anastomosis groups. Both arterial homografts and venous autografts were employed.

Several other reports of relatively poor results have also been published. Hohf and others[6] reported a 58.9 per cent overall failure rate in fifty-six patients with iliac or femoral occlusions whom fabric prosthetics were used were subject to a 50 per cent failure rate.

The largest clinical series reported to date is that of DeBakey,[8] in which 317 patients with fem-

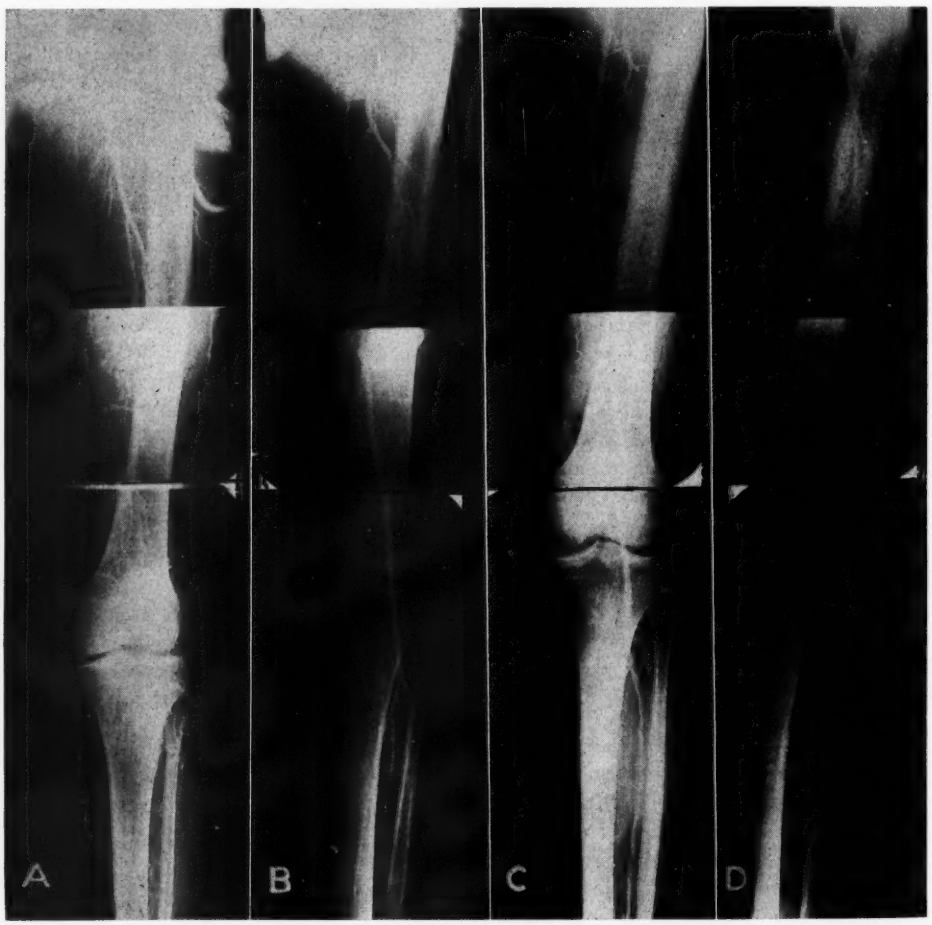

Fig. 2 (a) Femoral arteriogram in a patient with superficial femoral artery occlusion, and diffuse distal disease. No direct arterial surgery should be attempted in this type of case. (b) A long segment of the superficial femoral artery is occluded, but there is an excellent "run-off." Femoral by-pass was successful in this patient. (c) There is no complete block, but rather a diffusely diseased femoral artery, as well as occlusion of two of the three main vessels in the calf. Arterial surgery is not likely to be of much benefit. (d) A very long superficial femoral occlusion, with a patent distal arterial bed. By-pass was successful in relieving symptoms and in re-establishing pulsatile flow to the leg.

treated with by-pass operations utilizing arterial homografts and Edwards-Tapp nylon prostheses. The type of replacement material employed did not appear to affect significantly the eventual success rate.

Deterling,[7] in 1958, reported forty-nine cases of femoral-popliteal by-pass with a 28.5 per cent failure rate. In his hands, the homograft yielded an 80 per cent success rate while the patients in oral occlusions were treated with a by-pass procedure. There was an immediate 14 per cent failure rate and an additional incidence of 14 per cent late failures, of which approximately 7 per cent were salvaged by re-operation. Arterial homografts, nylon and dacron prostheses all seemed to yield essentially comparable results, although the present choice of DeBakey's group, for other technical reasons, is the dacron graft.

Enough experience has now accumulated to offer some guide to the vascular surgeon as to the probability of success in a given candidate for femoral by-pass. Since there is considerable confusion in the literature on this subject, it seemed worthwhile to review the experience of this clinic in an effort to determine the present accomplishment with this procedure, and to attempt to formulate a new set of criteria for operability. A clinicopathologic study was therefore made of all the cases in which femoro-popliteal by-pass for arteriosclerotic thrombo-occlusive disease was performed since the onset of such surgery in 1955. The period of this study ended in December, 1957, permitting a full year of follow-up on all patients.

80-89	2	0
90+	1	0
Total	29 (74.4%)	10 (25.6%)

Need for Treatment

It is important at the outset to outline the indications for surgical treatment in this group of patients. Massarelli and Estes[9] have clearly shown that the life of the patient with peripheral arteriosclerotic occlusive disease is not significantly endangered by this manifestation of his arteriosclerosis. While the survival rates for these patients are not as good as for the general population in the same age group, deaths are for the most part due to associated coronary and cerebral involvement. Occlusive disease is therefore in marked contrast to aneurysmal disease which poses the constant threat of rupture.

Incapacitating claudication is the primary indication for active surgical intervention in patients with peripheral arteriosclerotic occlusive disease. The delay or prevention of amputation in the patient with pregangrenous changes has been another indication. However, it is to be emphasized that, in the light of current results, the presence of an occlusive lesion alone is not sufficient justification to warrant surgery.

Clinical Experience

Forty-two femoro-popliteal by-pass grafts performed on thirty-nine patients constitute the clinical material reviewed in this study. The age and sex distribution of this group is summarized in Table I. As in most series of this type, the vast majority of the patients are males in the sixth or seventh decade of life. The incidence of associated diseases is indicated in Table III, and as might be expected, there is a high percentage of other manifestations of arteriosclerosis.

TABLE II. RESULTS OF FORTY-TWO FEMORAL-POPLITEAL BY-PASS PROCEDURES

Successful over 12 months	19 (45.2%)
Success continued to date	15 (35.8%)
Failures to date	
Death—operative	3 (7.1%)
Death later	7*
Amputation	
Within 6 months	7
After 6 months	2*
Graft occluded	
Within 8 months	7
After 8 months	2
Total	27

*Same patient.

All of the by-pass procedures were performed for arteriosclerotic occlusive disease of the femoral artery. In general, the grafts were placed from the common femoral to the popliteal artery. In eighteen cases an autogenous saphenous vein was utilized for the shunt, and in twenty-three cases an Edwards-Tapp crimped nylon prosthesis was used. One ivalon graft was employed. All of the cases were followed either until failure was evident, or for a minimum period of twelve months of palliation. While the failures are all well documented, several of the successes have only been contacted by letter. They are classified as successes because of persistent relief of preoperative symptoms, although no objective indications of graf patency are available.

TABLE III. CORRELATION OF ASSOCIATED CARDIOVASCULAR DISEASE WITH BY-PASS GRAFT FAILURE (BASED ON FORTY-TWO GRAFTS)

Condition	Success	Failure	Total
Hypertension (150/90)	7	14	21
Previous myocardial infarct	2	2	4
Previous CVA	0	2	2
Diabetes	0	6	6

Results of Treatment

Inasmuch as these patients have been operated on either for the alleviation of symptoms or to

postpone amputation, we have arbitrarily chosen a twelve-month period of palliation as sufficient to justify the procedure, and to classify such patients as successful.

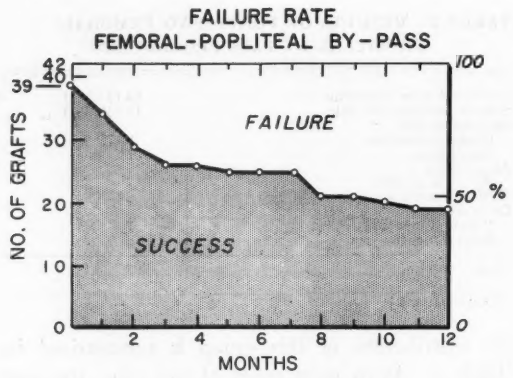

Fig. 1. Gradual decline in success following femoropopliteal by-pass is noted throughout the first post-operative year. However, most of the failures occurred during the first three post-operative months.

The results of these forty-two femoral by-passes are summarized in Table II. Nineteen, or 45.2 per cent of the patients, had twelve or more months of symptomatic relief following their operation. Four of these have subsequently developed evidence of graft failure (12 months, 15 months, 19 months, 23 months). The remaining twenty-three patients were classified as graft failures during the first post-operative year.

There were three operative deaths (7.1 per cent). Nine additional patients were subjected to major amputations following femoral by-pass on the same extremity. It is significant that whereas the greatest number of failures,[10] occurred during the first three postoperative months, there was a gradual increase in the failure rate through the first postoperative year (Fig. 1).

Discussion

In view of the high eventual failure rate of the femoral by-pass procedure at this clinic, an analysis of cause seemed indicated. For this reason, the clinical charts, operative reports and arteriograms of all of these patients have been reviewed, and an attempt has been made to redefine the criteria necessary for a chance of a successful end result.

Age and Sex.—A correlation of age with the eventual success of this procedure revealed that patients in the fourth and fifth decades of life as well as the very elderly patients (over seventy years) had a very low success rate. Indeed, there have been only two successful cases in the thirteen patients in this group who were over the age of seventy. Since this age also appears to be the upper limit of mortality-free elective abdominal aneurysm resection in this clinic,[10] it may well be a logical dividing line for elective surgery in patients with severe and diffuse manifestations of arteriosclerosis. Perhaps patients over seventy years should be excluded from consideration for this procedure.

There does not appear to be any correlation between sex and eventual graft success in this series.

Preoperative Duration of Symptoms.—Among eight failures treated within three months of the onset of their symptoms are five patients in whom gangrene was the indication for treatment. Of the total group of seven patients with gangrene, there has been one successful graft; one additional patient was successfully managed with a transmetatarsal amputation following by-pass. Four of these seven patients died, and above the knee amputation was necessary in the remaining case.

The group of patients treated for claudication appear to have a poorer prognosis with increasing duration of symptoms.

Associated Cardiovascular Disease.—Table III indicates the percentage of patients with associated arteriosclerotic disease in this series of thirty-nine patients. Note that none of the six diabetic patients had a successful result. On the other hand, Humphries[11] has reported successful results in diabetic patients. Neither of the patients with previous cerebrovascular accidents had a successful result. The percentage of hypertensives in this group of patients (53 per cent) is quite similar to the incidence (56 per cent) reported for patients with aneurysmal disease.[10]

Preoperative Arteriography.—The preoperative femoral arteriogram is probably the most important single item in the proper selection of patients for the by-pass procedure, and should be performed upon all prospective surgical candidates in whom no other contra-indication to surgery is present. In particular, the information gained from the arteriograms regarding the quality of the vessels proximal to the blocked segment, the length of the block, the number and size of the collateral

vessels, and most important, the status of the vascular bed distal to the obstruction, is invaluable. This information is frequently the sole basis for avoiding unnecessary explorations, while permitting surgery in the greatest number of suitable cases. To be of maximum value, the arteriogram must accurately delineate the degree of arteriosclerotic change in the distal arterial tree. Toward this end, the development of biplane femoral arteriography may offer some additional information as to the true status of the occlusive process, since a thin ribbon-like lumen may appear to be widely patent if x-rays are taken in only one plane.

A further adjunct in femoral arteriography at this institution has been the recent employment of serial techniques of a somewhat more precise nature than had been the previous custom. With a rotating casette holding four 7" x 36" films, four x-rays of the lower extremity may be obtained at any set interval. With this method, uniformly excellent angiograms, particularly of the distal arterial bed, have been obtained.

If complete arterial occlusion is present, and the collateral circulation is inadequate to fill the distal arterial tree, distal operative arteriography, as advocated by Barker,[12] should be employed at the time of popliteal artery exploration.

An indication of the importance of preoperative arteriography and its proper interpretation is revealed by the recent report of Wylie and Goldman,[13] in which they indicate that of 199 patients with clinical findings suggestive of femoro-popliteal occlusion, 61 per cent were inoperable because of extension of the disease into the distal popliteal artery, and diffuse disease in the proximal vessels.

The preoperative arteriograms of our patients were reviewed carefully with the above items in mind. In general, no new prognostic signs were discovered. However, the following findings should be noted:

1. In a number of cases the standard arteriogram did not show enough of the distal arterial bed to be diagnostic. In such cases serial or operative popliteal arteriograms should be done before by-pass is attempted.

2. In patients with poor arterial inflow and evidence of multiple partial blocks, poor results are the rule.

3. The patient with a single short segmental block and otherwise normal arterial tree was uncommon in our series. Most arteriograms revealed a considerable amount of arteriosclerosis in a number of the vessels.

4. The presence of a large number of collateral vessels, both proximal and distal to the block, is still compatible with a successful result, providing the main distal arterial channels are also patent.

5. The arteriogram frequently underestimates the length of occlusion and the degree of intimal involvement.

TABLE IV. CORRELATION OF TYPE OF GRAFT WITH BY-PASS FAILURE

Graft	Success	Failure	Total
Autogenous vein	10	8	18
Tapp-Edwards nylon	5	18	23
Ivalon	0	1	1
Total	15	27	42

Prostheses.—Ten of the eighteen patients in whom autogenous veins were implanted have remained long-term successes (Table IV). Only five of the twenty-three patients in whom Edwards-Tapp Prostheses were used have remained successful. This information correlates well with other reports of late occlusion with these grafts.[14,16] In addition, it raises the question as to the most suitable prosthetic device currently available. The reports of Szilagyi[15,16] and Barnes[17] have indicated the high failure rate which may be expected with the use of arterial homografts. In general, this is due to the variable acceptance of the homograft by the host and the eventual dilatation, tortuosity, aneurysm formation and rupture of an important percentage of arterial homografts. Autogenous veins may still have a place in this procedure. Linton[18] beileves the autogenous vein is the best graft currently available. Only a long term follow-up of a large group of patients will determine this.

Dacron and teflon are considered the most satisfactory materials for vascular prostheses at this time.[19] The work of DeBakey[20] and Szilagyi[16] involving the clinical use of dacron has been particularly satisfactory. The extensive laboratory studies of Harrison[21,22] have indicated that teflon is, at least on a physiochemical basis, probably the most suitable plastic presently available, and the initial clinical experience of Merendino and his co-workers[23] has also been quite satisfactory with this material. Both teflon and dacron are currently employed in this clinic.

Surgical Technique.—An additional factor of some importance is the variability of surgical tech-

niques employed for this procedure. Sixteen surgeons performed the forty-two femoral by-pass grafts reported here. There is little doubt that a carefully performed anastomosis and a limited and meticulous dissection considerably influence the eventual outcome of the procedure.

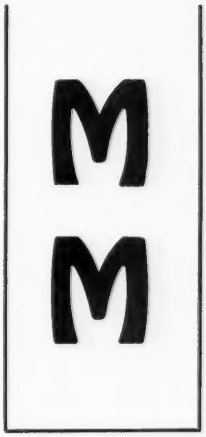
Summary

A group of forty-two patients in whom femoropopliteal by-pass has been performed is presented. Of these, nineteen patients have had at least twelve months of relief of symptoms and fifteen patients continue to have evidence of patent grafts.

Arteriosclerotic occlusive disease of the femoral artery is a slowly progressive condition which may lead to claudication, gangrene, and the eventual loss of a limb. The alleviation of symptoms is the only indication for direct arterial surgery in these patients.

More careful selection of patients for femoral by-pass must be employed in the future. The operative risk in patients with diffuse arteriosclerosis is considerable, even for relatively minor procedures. Patients over seventy years will rarely be candidates for this procedure. Patients with diabetes or gangrene were rarely benefited in this series.

The importance of adequate preoperative femoral arteriograms is stressed. The distal arterial bed must be shown to be patent by preoperative examination or by distal operative angiography for successful results to be anticipated. The use of serial angiographic techniques and biplane studies have been suggested as two methods of achieving this end.



Teflon and dacron appear to be the most promising prosthetic materials currently available. The venous autograft still appears to have a place in the femoral by-pass procedure. There was a high incidence of occlusion with the Edwards-Tapp nylon graft in this series.

With more careful preoperative selection, better arteriographic evaluation, more meticulous operative technique, and more reliable prostheses, a greater number of good results may be expected in patients submitted to femoral by-pass in the future.

Tinnitus, Vertigo, and Deafness

LAWRENCE R. BOIES, M.D.
Minneapolis, Minnesota

Presented at the Clinical Session of the American Medical Association, Minneapolis, Minnesota, December 2, 1958.

THIS title was given to me. I would not have been presumptious enough to have chosen it on my own; it is too big an order. In my own mind, I have modified it to read: What is there that is new about tinnitus, vertigo and deafness? These are time-worn terms. Every practitioner of medicine encounters these symptoms and knows that those afflicted can have real problems.

Tinnitus

Tinnitus may be defined as a sound experience perceived by the patient and which originates within himself. The word is derived from the Latin word "tinnire" meaning to jingle. A majority of those who have this symptom relate it to one or both ears and more commonly describe it as a singing sound, or a buzzing, or a sound like escaping steam and, less commonly, as a whistle—or actually as a sound as of a bell. Sometimes the patient cannot localize it and refers it to the center of his head. This suggests that the sound actually originates in both ears but because it is of the same pitch and loudness it is not referred to an ear; or, it suggests that the origin of the sound is not within the ear but arises in the neural mechanism of the central nervous system.

Etiology.—Figure 1 diagrams the location of the several causes of subjective tinnitus. These include: (1) pathologic disturbances in cochlear hair cells or ganglion cells from toxic causes, impairment of blood supply, et cetera, (2) the physical distortion of endolymphatic hypertension as occurs in Ménière's disease, (3) central nervous system disorders such as atherosclerosis or cerebellopontine angle tumors, (4) alterations of sound conduction from cerumen, middle ear fluid, otosclerotic fixation of the stapes, (5) vascular middle ear pathology such as inflammatory granulomata, extensive otosclerotic foci and carotid body-like tumors, and (6) clonic contracture of middle ear muscles.[1]

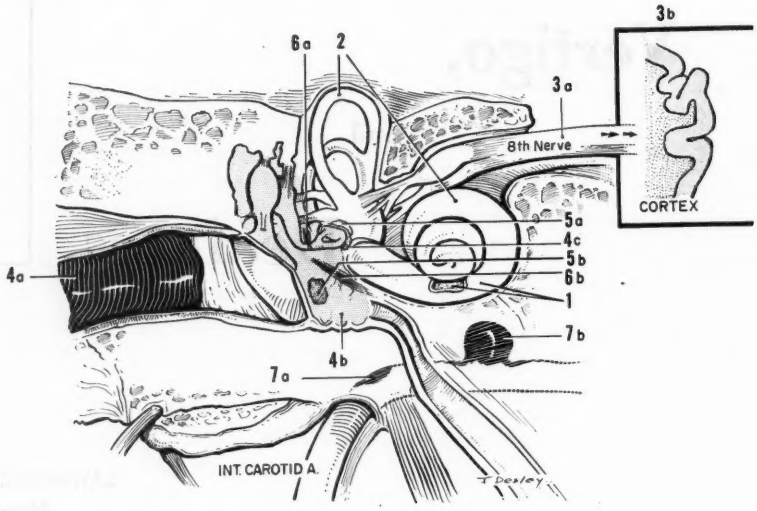

Fig. 1. A diagram (after Hilger) showing the sites for the etiology of tinnitus.

1. Pathologic alteration in cells of the cochlear sensory system
2. Endolymphatic hypertension (physical distortion of the cochlear sensory system)
3. (a) Certain disorders affecting the eighth nerve such as tumor
   (b) Certain disorders in the brain such as cerebral atherosclerosis
4. Alterations of sound conduction
   (a) from impacted cerumen
   (b) from fluid in the middle ear
   (c) from limited otosclerotic fixation of the stapes
5. Vascular middle ear pathology
   (a) vascular and extensive otosclerosis
   (b) carotid body-like tumors, inflammatory granulomata, et cetera
6. Clonic contraction of middle ear muscles
   (a) stapedius muscle
   (b) tensor tympani
7. Cervico-cranial vibratory phenomena
   (a) atherosclerotic narrowing
   (b) aneurysmal dilatation

(Through the courtesy of J. A. Hilger and W. B. Saunders Company).

Additional causes of sound in an ear may be one that the patient actually hears such as his own respiration in the form of a blowing sound past a constantly patent eustachian tube, or vascular eddying in a carotid artery due to aneurysmal dilatation or atherosclerotic narrowing.

A listing of the possible causes of tinnitus presents nothing that is new. As one reflects on these possibilities, however, it seems that a new emphasis

must be placed on the idea that "the patient is best served when the symptom of tinnitus is viewed in the broad medical sense as an indication for thorough-going otologic and general medical examination."[1]

The only positive treatment is the correction of the cause. In many instances the pathologic changes that have occurred are irreversible.

Vertigo

This symptom seems to be on the increase. As our knowledge has grown in recent years concerning the delicate neural mechanism in the membranous labyrinth that is concerned with equilibrium, and we consider the fact that the blood supply to the labyrinth is a terminal one without collateral circulation, an increased awareness of the possibilities of autonomic dysfunction has developed. This could explain many of the temporary vertiginous experiences for which no other cause is found.

Acute obstruction of a eustachian tube and the pressure changes that may occur when the patient relieves it by swallowing (or auto-inflation) may also produce an acute but transient vertiginous attack, because of acute pressures on the round or oval windows.

Etiology of the Major Sources of Vertigo.—There are five categories of etiology: (1) Cholesteatoma in a chronic middle ear and mastoid antrum in which the horizontal semicircular canal is eroded. (2) Disorders that are primary in the vestibular labyrinth, toxic causes such as the injury from streptomycin, viruses (mumps is a specific example) et cetera, and vascular causes. (3) Vestibular neuronitis (ganglion cell involvement). (4) Disorders within the eighth nerve from neoplastic growths or toxic neuritis. (5) Vertigo that is of central nervous system origin.

Vertigo can be classified into two types: *primary* and *residual*. In the primary type, the initiating stimulus originates somewhere in the vestibular system—usually by an active disease process—and occurs without relation to movement. In the residual type, an injury has occurred to vestibular sensory or neural elements disturbing their function and the vertigo occurs when a normally occurring vestibular reflex cannot function because of this defect. When the vertigo occurs as the result of the patient's movement such as tipping his head back to look upward or rolling over in bed, it is termed *postural* vertigo and if nystagmus is elicited on testing it is termed *positional* nystagmus.

"Residual vertigo then is evidence that injury has occurred in the vestibular system. This vertigo will continue as a response to movement until repair is complete or compensation occurs."[2]

Consideration of all of these possibilities in etiology should emphasize the importance, in the presence of this symptom, for a complete otological examination, and a general physical study including a neurologic evaluation. When these studies have been completed, the final diagnosis may be reached only by a process of exclusion. That is not true, however, in the severely disabling Ménière's disease. This disorder can be diagnosed from the history and by specific tests. The history is characteristic—such as aural pressure in the early stages, fluctuating hearing loss with relatively good preservation of the high notes in the early stages, tinnitus and paroxysmal attacks of vertigo, early loss of discrimination as determined by speech audiometry, and positive tests for recruitment.

Treatment.—Surgical therapy can produce a cure for the cholesteatoma. Removal of an eighth nerve tumor may also be curative. Ménière's disease usually responds to intensive therapy consisting of vasodilatation, limitation of sodium intake and diuresis, if the patient adheres faithfully to a strict regimen of therapy. Uncontrolled cases which are unilateral (a majority of them are) may be relieved by a relatively simple surgical procedure and bilateral involvement might be relieved in selected cases by streptomycin through destruction of the neural elements particularly vulnerable to the toxicity of this antibiotic.

Deafness

Otologists do not like the word deafness. There is a tendency to substitute the terms "hearing loss" or "hard of hearing" whenever possible and reserve the well-worn word "deafness" for the degree of loss which requires amplification for communication.

Medical students have been taught for years that the lesions involving the inner ear cause *perception* or *nerve* deafness. Improvements in the tests for hearing loss have made better differentiation possible in the location of the lesion and now we are substituting the term "sensory-neural" for those

terms previously used, inasmuch as the lesion may be anywhere from the end organ into the brain.

Considerable progress is being made in the cases of hearing loss caused by impairment of conduction.

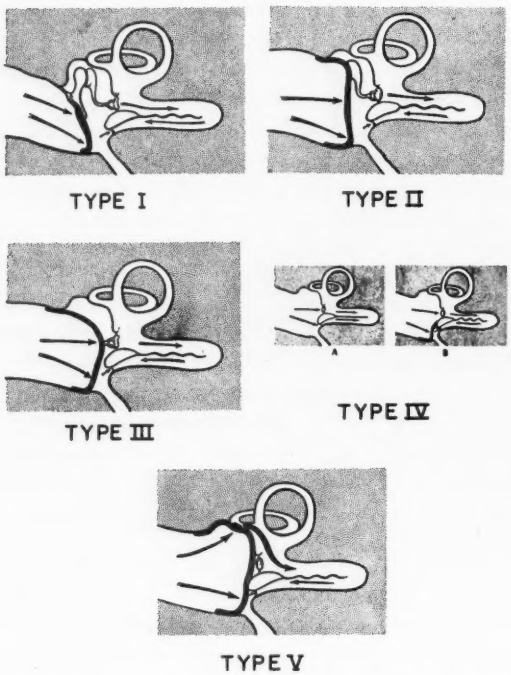

Fig. 2. Schematic representation (after Goodhill) of the types of problems encountered in the restoration of tympanic function damaged by chronic middle ear and mastoid disease. Type I consists of grafting an ear drum perforation and is designated as a myringoplasty. Type II is an expanded myringoplasty in which the malleus has been removed in the course of the disease, or by the surgeon, and the complete drum is replaced by a graft in contact with the incus. In Type III the stapes alone remains of the ossicular chain and the drum is completely replaced by a graft which contacts the stapes and a reduced air-containing tympanic cavity functions. In Type IV a small aid-containing cavity is created by a graft attached to the promontory extending over the tympanic orifice of the eustachian tube and attached to the outer inferior margin of the middle ear space. The stapes is gone in these cases but an oval window membrane functions. In Type V the oval window does not function and a fenestra is made in the horizontal canal. An extensive skin graft creates a minor tympanic cavity as in Type IV and also covers a newly created window in the horizontal canal. (Through the courtesy of Victor Goodhill and W. B. Saunders Company.)

Conduction Loss

Tympanoplasty.—The new surgical procedures done with visualization through a microscope, and grouped under the title of tympanoplasty, can restore useful hearing in many cases of damaged middle ear conduction mechanisms (Fig. 2). In fact, the term radical mastoidectomy is probably on the way out since these new procedures bid to replace the old techniques which in relatively few cases improved the hearing function.

The objective of the tympanoplastic procedures is to remove chronic suppuration, or the sequelae of this suppuration if the ear has become dry, and then to restore an air-containing tympanic cavity across which sound pressures can reach the inner ear, preferably by creating a mobile membrane that will be in contact with the remains of the ossicular chain. Limitations on what can be accomplished depend upon what is missing and the extent of cicatricial middle ear impairment. Needless to say, there is a vast reservoir of these cases to work on and it would seem reasonable to predict that as experience with these procedures increases, the successful results will increase.

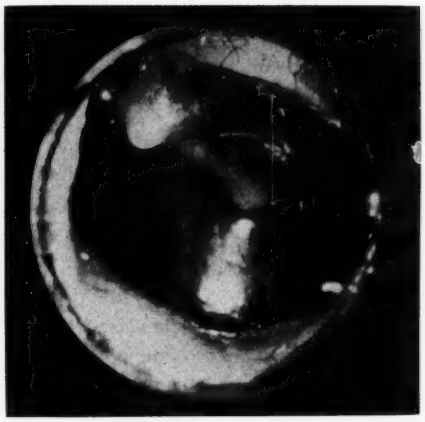

Fig. 3. Airless middle ear filled with dark hued serous fluid. This is due to eustachian tube obstruction. The ear drum is sharply retracted. The short process of the malleus is very prominent and the hand is drawn inward.

"Fluid" Ears.—Another activity that is common today and seems to be increasing is concerned with the management of what are rather loosely called "fluid" ears. Transudates of serum into the middle ear result from acute eustachian tube closure, with the transudate occurring when negative pressure of a sufficient degree develops in the tympanic cavity (Fig. 3). If this closure is temporary there is no particular problem. If it is initiated by an allergic or inflammatory change in the mucosa of the tube and an exudate fills the tympanic cavity, the character of this secretion makes resolution less

likely, particularly when the eustachian tube does not perform normally because of persistent edema within it or at either of its two openings. One example of this problem that is common today is the case of the child who develops an acute otitis media, has his upper respiratory tract "sterilized" by the use of an antibiotic, and three or four weeks later has a noticeable impairment in hearing and is found to have middle ears filled with mucoid secretion which when removed by aspiration through a myringotomy opening provides an immediate improvement in hearing. Untreated, or with the subsequent attacks that are also inadequately treated, these situations are prone to lead to permanently damaged middle ear function. The answer to this problem involves an adequate follow-up of the middle ear after an episode of acute otitis media, myringotomy for drainage when indicated, and attention to any abnormal conditions in the upper respiratory tract which affect the normal functioning of the eustachian tube. The number one offender in children is abnormal lymphoid tissue in the nasopharynx and oropharynx and the number two offender is probably allergy. The author has observed that chronicity in these middle ear problems is more likely to develop in temporal bones in which there is limited or practically absent pneumatization.

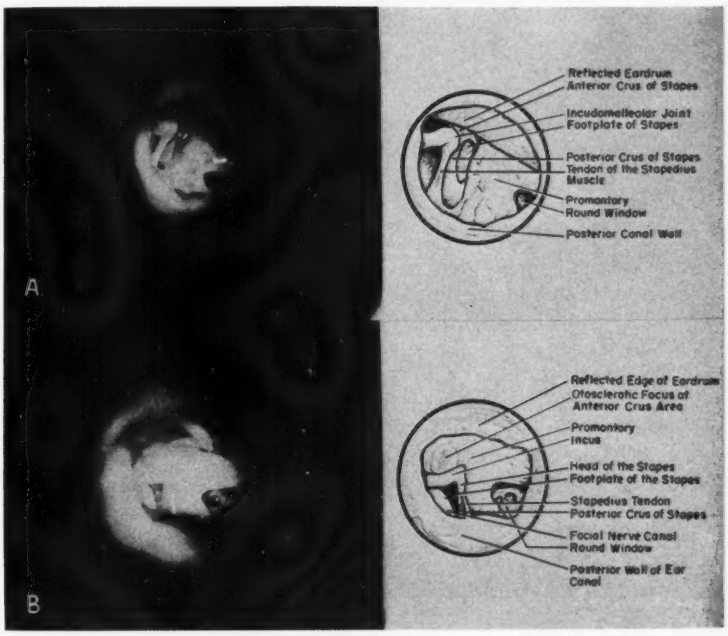

Fig. 4. (A) An actual photograph (after Hough) of what the eye may see through the operating microscope (Fig. 5) focused on the normal middle ear. (B) A case of otosclerotic growth in the area of the anterior crus. There are many variations in the extent of the otosclerotic growth. The one depicted here is an example of a case in which the chances of a successful result in stapes mobilization surgery is greater than it would be with a more extensive growth. (Through the courtesy of J. V. D. Hough and the W. B. Saunders Company.)

Otosclerosis

We have not learned anything that is really new about the etiology of otosclerosis in recent years, but it is probably safe to say that we have seen a lot more of it. There seems to be no evidence that it is on the increase but it is certainly diagnosed more often. The author believes that progressive hearing loss, with evidence that it is in the conduction mechanism, in the absence of evidence of middle ear inflammation must be due to otosclerosis. A generation or more ago, many of these cases were classified under the category of "chronic catarrhal deafness." The observations of those who have had a considerable experience with the surgery for otosclerosis would support these contentions.

The Surgery for Otosclerosis.—The operation that is known as the fenestration is not new but it has reached a high state of perfection in recent years as done in one stage. Also, the stapes mobilization operation cannot really be classified as entirely new since it was done over fifty years ago, but the techniques and successes are new. Under rather simply induced and adequate local anesthesia, the ear drum is reflected forward, some bone may or may not be removed from the posterior annular rim, and the incudostapedial joint and footplate area are visualized under microscopic magnification (Figs. 4 and 5). Then comes the problem of loosening the footplate without violating the integrity of the stapes and its joint with the incus. There is a great variation in the footplate conditions that the operator finds. In some, the growth produces only a limited fixation. The reason that the operation is at all successful when the mobilization is done through otosclerotic bone is that apparently a fracture through this type of abnormal bone tends not to heal.

Techniques have changed for improvement as experience grows. Many otologists now attack the footplate directly with picks or tiny chisels. Fortunately, the principal otosclerotic focus in a majority of cases is at the anterior crus (which is usually better visualized than the posterior crus) and a loosening of the ankylosed footplate at this site, a crurotomy or even a fracturing-loose of the posterior two-thirds of the footplate with a mobile posterior crus, may be attended by success. A variety of other procedures are now being tried in difficult cases such as an opening in the footplate covered with a graft and the substitution of an artificial stapes. In the present state of our knowledge and in the more experienced hands, permanent success is probably attained in approximately 50 per cent of the cases treated by surgery.

Fig. 5. The Zeiss operating microscope (Otoscope) perfected by Lempert is now widely used by otologic surgeons. Sterile drapes cover the parts adjacent to the field of operation; 6, 10, and 16 diopters of magnification are most frequently used; 40 diopters are available.

Relatively rare as a cause of interference with the conduction of sound pressures to the inner ear are the congenital conditions of the external ear. These vary in form from almost a completely rudimentary external canal and ear drum, along with malformations of the ossicular chain, to lesser degrees of these abnormalities. In some of these cases, surgical exposure of the middle ear and a skin graft to serve as an ear drum may substantially improve the hearing.

Sensory-Neural Hearing Loss

Relatively little can be accomplished in the treatment of hearing loss that has become established on a sensory-neural basis. Our hope lies in prevention. The one exception is with the lesion in the end organ previously referred to as "endolymphatic hydrops" or "endolymphatic hypertension." Some clinical manifestations of this are anything but new. Ménière gave an excellent description of them nearly a century ago. Early recognition of the disorder, and adequate and continued therapy may restore and maintain good hearing in many instances.

Aids to Hearing

Technical progress has advanced the performance and acceptance of the hearing aid. Currently so-called "hearing glasses" have a popular appeal and a binaural fitting has merit in certain cases. Small aids that fit behind the auricle or in a woman's hair with short communicating tubes to a flesh-colored plastic insert in the external canal are also popular. Some very small models have also been developed in which the whole mechanism is worn in the meatus of the external canal. The satisfactory use of these latter units may be accepted by patients in whom limited amplification is needed.

Additional progress that merits comment is the disposition of the modern otologist to know something about the prescribing of the aid for his patient. In the past, too much of this task has been left to hearing aid dispensers who have a heavy financial interest in the transaction. It is only natural that the handicapped patient whose hearing loss has led him to consult an otologist should expect specific directions and not confusion in purchasing help from representatives of the highly competitive hearing aid industry, many of whom participate in aggressive advertising.

Audiology

A new specialist has been accepted on the horizon of otology in recent years—one who has graduate college training in the problems of hearing and speech. In the author's opinion, the audiologist's major clinical contribution is in the measurement of hearing in the deaf infant and child and guidance of such patients in their education. An additional clinical function of the audiologist is in presiding over clinics for *problem* cases of deafness whose only chance for a workable means of communication lies in the use of a hearing aid. In performing these functions, research in the means of accurately assessing the degree of hearing loss and the location of the lesion has been another important contribution.

This new specialist in audiology should not be confused with the commercial "certified hearing aid audiologist" who sells hearing aids.

Summary

1. The symptom of tinnitus calls for an otologic examination and usually a subsequent thorough general medical examination.

2. A major vertigo problem is another otic symptom demanding thorough otological study and usually a neurological assessment should not be omitted. When a major problem, it is less often dependent on systemic disorder than is the symptom of tinnitus.

3. The term "sensory-neural" hearing loss is being substituted for "perceptive" or "nerve" loss.

4. Notable recent progress has been made in microsurgery on the middle ear to improve conduction losses due to damaged middle ear mechanisms and to mobilize the stapes in otosclerosis.

5. The otologist is assuming a more active role in guiding his deaf patients in the use of aids to hearing for which improvements have provided marked technical progress and increased acceptance. The audiologist who is trained as a specialist in speech and the measurement of hearing is proving to be a valuable member of the clinical team —particularly in the areas concerning education of the deafened child and in the rehabilitation of adults whose deafness will not respond to medical or surgical therapy.

Graphic Monitoring of Seizure Incidence Changes in Epileptic Patients

EUGENE A. JOHNSON, Ph.D.
ERHARD HAUS, M.D.
FRANZ HALBERG, M.D.
GEORGE L. WADSWORTH, M.D.
Minneapolis, Minnesota

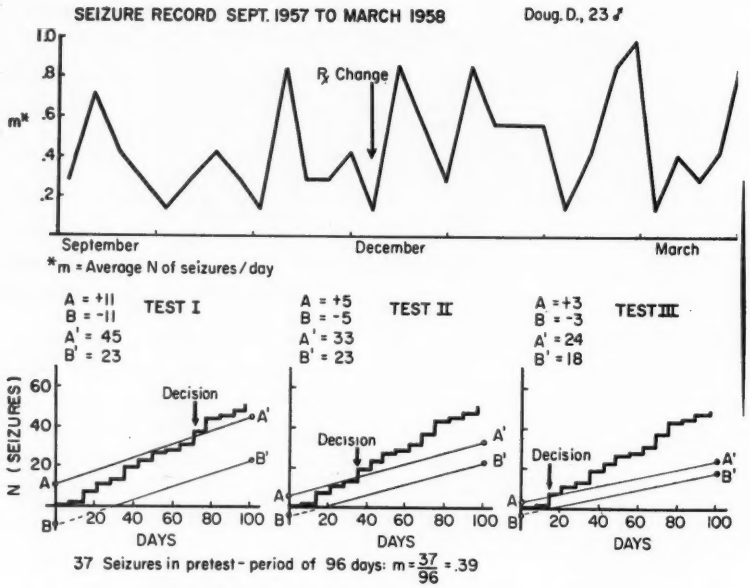

Fig. 1. Comparison of three sequential tests, applied at start of an apparently unsuccessful medication change.

IN PATIENTS with convulsive disorders, fluctuations in seizure frequency are common; the problem of the significance of these fluctuations is germane to the clinical evaluation of the course of the disease and particularly to research on anti-convulsant drugs. Pertinent statistical procedures were in the past, however, usually applied retrospectively, at intuitively picked intervals and to seizure data from groups of patients, rather than from individuals. The tests involved considerable computation and their uses remained limited mostly to research projects.

For medical practice, particularly in conjunction with anti-convulsant therapy, statistical methods seem desirable. How significant are the fluctuations of seizure incidence in a given case? This question constitutes a statistical facet of the clinical problem. It is related to the question: To what extent, if any, may seizure incidence changes be related to the use of a given drug? In attempts to obtain reliable answers, however, a third question arises: For how long should a certain medication be tried? This third question constitutes the main point of the following discussion; its ethical solution might involve, i.a., analytical statistical considerations.

Usually, the longer the period following a medication change, the better the chance to avoid erroneous decisions and yet, one may leave the patient on a useless or harmful treatment for too long. Also, one should not delay increasing a certain drug, first given in low doses, once its beneficial effect is ascertained. Whether a given medication should be continued, therefore, should be decided as soon as reliably possible. The significance of fluctuations in seizure incidence contributes heavily to the objectivity of such decisions,

From the Cambridge State School and Hospital, Cambridge, Minnesota, and University of Minnesota Schools of Medicine and Public Health.
Supported by the Department of Public Welfare, State of Minnesota; United States Public Health Service; and Elsa U. Pardee Foundation.

other things being comparable. These decisions will most likely involve error whether one waits too long or not long enough. Can one then predetermine the risk of error and thus reduce it to an acceptable degree?

In medical practice, answers to such questions have been sought intuitively, while reliable tests were unavailable or impracticable. Moreover, in practice, it does not suffice that a test be objective; its results must pertain to the individual patient rather than a group. Also, until decisions are reached, testing remains a constant problem. How often should one test? This depends upon seizure incidence. In selected cases, with many seizures per day, daily tests, including weekends and holidays, may be helpful.

Such requirements limit the choice of suitable techniques. Only an easy procedure may be used day after day. If the test is simple, however, its day-to-day performance may be assured by delegation to non-professional personnel. Furthermore, if the test is easily interpreted as well as easily performed by the same personnel, it can serve as a monitor (which is "automatic," as far as the physician is concerned).

Statistical tests applied with the foregoing thoughts in mind will be briefly sketched. Their limitations, some of them serious ones, will be noted. Within their limits, such tests may be monitors of change in seizure incidence and they may also help to make decisions as to the significance of incidence changes. The tests apply to certain (but not all) cases of epilepsy. Their usefulness in medical practice (and research) can be extended, however, to problems posed by disease other than certain convulsive disorders.

The procedure is graphic, it can be set up with minimal arithmetic and thereafter continued (done and interpreted) with *no* computation. The method involves sequential testing, a so-called "stop-go" scheme.

What is Sequential Testing?

Sequential analysis is a method of statistical inference whose characteristic feature is that the number of observations required by the procedure is not determined in advance; the decision to terminate depends at any time on the results of the observations previously made.[1] Sequential analysis was developed during World War II by Wald[1] and classed as a military secret. Since the end of the war, it has been widely used in industrial applications. Several biologic applications,[2,3] including clinical research[4-14] have also been discussed.

For clinical experimentation, Bross[4] has emphasized that sequential tests, as compared to the usual fixed sample procedures, offer three important advantages. First, data may be analyzed as they come in without necessarily waiting for analysis until the end of a fixed and often arbitrary period. Second, valid conclusions may be reached statistically with an appreciable reduction in the total amount of data collected. Third, Bross also noted that *all* computations on the part of a research worker may be eliminated. Lasagna and Meier[15] and in turn Armitage,[8,16] have emphasized the limitations as well as the advantages of sequential testing.

The Tests.—The theoretical basis for the particular procedures suggested below was developed by Dvoretzky and others.[17] These authors' formulae[17] were adapted to the problems of epilepsy and underlie the present methods.

Three simplified tests will be outlined for use in general and neurologic practice. The procedures will be denoted as Tests I, II, and III. With each of these (and with analytical statistics "built-in") one may arrive at one of two decisions: either a "reduction" in seizure incidence or "no reduction." These alternative decisions are made with the risk of error largely predetermined. Clinically, the decision "no reduction" in seizure incidence also is important as is the alternative "reduction." Either decision may stop a given treatment from being continued too long.

The three tests to be outlined differ in sensitivity of detecting a change in seizure incidence (as being statistically significant). They also differ in the time periods required for decisions, which are longer for Test I, as compared to Test II, and shortest for Test III.

Test I is very likely to detect a reduction of seizure incidence by as little as 25 per cent (i.e., to 75 per cent of previous seizure density). Tests II and III, on the other hand, are not very likely to detect changes in seizure incidence unless reductions by 50 per cent or by 75 per cent, respectively, have occurred.

Test criteria for the three procedures were chosen to meet the more common clinical needs with a minimal number of tests. Minor modification of the procedures outlined below will suffice, however, for more specific adaptations in particular cases and especially in research.

The predetermined risk of error with respect to a decision of "no reduction" (when reduction has occurred) is largest for Test III, intermediate for Test II and smallest for Test I. All three tests are so constructed, however, that the likelihood of erroneously claiming a reduction in seizure incidence (i.e., of doing so in case of no reduction) is less than 5 per cent.

Let α denote the risk of *erroneously* deciding "reduction" (when none has occurred) and let β denote the risk of erroneously deciding "no reduction" [when reduction by 25 per cent (Test I), by 50 per cent (Test II) or by 75 per cent (Test III) has occurred] (cf. 18). If the assumptions of Dvoretzky et al.[17] would be valid for each case of epilepsy tested, $\alpha=\beta=.04$, in the case of Test I; .03 in Test II; and .0154 in Test III. Actually, these values are approximations; the assumption of a truly random seizure incidence forms the basis of testing and it is unlikely that this assumption is strictly valid in most cases.

For those wishing to limit themselves to a single procedure, Test II may be recommended as the more generally useful method.

Variable Tested.—In cases with mixed seizure types, one may use a separate graph for each clinical type or a weighted seizure index instead. Clinically, the former more cumbersome approach seems the more appropriate. Testing might be restricted, however, to more prominent seizure types (for example, one may refrain from sequential testing in the case of petit mal attacks if most of them are likely to be overlooked).

Any evaluation of seizure data is as reliable as is the observation and interpretation of the seizures themselves. The nature of the variable plotted thus will be a function of the competence of the observers. From a statistical viewpoint the important point remains that the test deals with *changes* in number of observed seizures, rather than with the exact numbers of seizures as such. Thus, testing might be feasible if a certain number of seizures are missed (as may be the case even for grand mal seizures, particularly if they occur at night). A requisite for reliable testing is the comparable caliber of observation (for example before and after medication change), rather than an exact record of each seizure.

Requirements for Testing.—1. Seizure incidence (for example, as average/day = m) during an appropriate period prior to testing must be known or estimated.

The choice of pre-test period (the period selected for computing m) should be made with several points in mind, each of which is subject to qualifications. First, this period should be as close as feasible to the start of testing. However, when a lower seizure incidence was recorded prior to an ineffective change of medication, one may compute m for that earlier period (rather than for the subsequent but unsuccessful trial period). In other cases as well, one might deviate from the rule of using as the pre-test period the time elapsed between the last earlier medication change and the start of a new one to be tested. Among several successive periods on different medications, one may choose for computing m that with the lowest seizure incidence, unless such low incidence prevailed in conjunction with side effects that necessitated a change.

Next and only theoretically, the pre-test period ought to be sufficiently long so as to allow for establishing randomness by appropriate statistical tests[19-21] (see 2 below). In practice, however, periods of such length are not likely to be available and therefore, the statistical verification of the assumptions underlying testing usually will be lacking. One might merely note, in this connection, that the lower the seizure incidence, the longer should be the pre-test period and also that periods involving very frequent therapy changes should not be considered for computing m. One might stipulate that the period selected for computing m should be clinically representative, but this obvious requirement will have to be judged only by clinical intuition in many cases. Along related lines of thought, one might wish to consider cases for which written incidence records are unavailable. Whether or not in such cases one might use an m estimated by a custodian or institutional aide will depend largely on the confidence that one places in such estimates. It can hardly be overemphasized, however, that it is the validity of the estimate of m upon which the rigor of testing critically depends. This must be kept in mind, while we turn to the next point.

2. Seizure incidence should be superficially random (preferably ascertained as such from written records). If the seizures form "clusters," for instance, at certain times of day, the seizure pattern may be made artificially random by summation over one or a few days.

Unless other provisions (not discussed herein) are made, cases with "clusters" of seizures at

longer intervals (for example of several weeks around menstruation) may not be tested. It also may be impractical to apply these tests in cases with a relatively low seizure incidence unless plotting (see below) is done at longer intervals.

3. For the test period proper, arrangements should be made for the recording of seizures by a custodian at home or by an institutional aide.

Preparation of Graph.—1. Mark off *time* (in days) on a horizontal scale and the *number of seizures* vertically (see figures). Horizontally, day 0 is on the extreme left and day 100 on the right. The vertical scale is drawn as a function of expected seizure density, with 0 number of seizures placed at the intersection of the two scales; this scale is extended below the 0 point, for the placing of B [(2) below].

2. On the vertical scale, place points A and B, at +5 and —5, respectively, for Test II (see figures). (For Tests I or III, A and B will be at +11 and —11 or at +3 and —3, respectively).

3. Count number of seizures recorded during pre-test period. Express the pre-test incidence of seizures as average per day, to be denoted as *m*.

4. For Test II multiply *m* with 72, to obtain product P. (To obtain P in Tests I or III, multiply *m*, with 87 or 54, respectively).

5. Product P serves for computing A′ and B′. A′ is P + A and B′ is P + B. Thus, for Test II, P + 5 will be A′ and P —5 will be B′ (see figures). [In Tests I or III, use P + 11 and P —11 or P + 3 and P —3 (for A′ and B′), respectively].

6. Place A′ and B′ on the graph above the 100-day point on horizontal scale and at height indicated by vertical scale.

7. Draw straight lines connecting A with A′ and B with B′. The two lines should be parallel; they are the boundary lines for sequential testing.

Plotting of Seizure Line.—An intelligent custodian at home may be trusted with plotting. Otherwise, arrange for the reporting of seizures at suitable intervals (e.g., to the physician's secretary). Ward personnel also may be charged with plotting, but, in the institutional situation, reporting to the central office may be preferable. The higher the seizure incidence, the shorter should be the plotting intervals.

Plot a seizure line by starting at 0 days. During periods without seizures, move the line horizontally to the right, over a distance corresponding to the period plotted. During periods with seizures, move the line up, obliquely, to a point found by moving first horizontally to the right over the appropriate distance and then straight up, over as many units on the vertical axis as the number of seizures during that period. At any one time, the last point on this line (the seizure line) represents the observed seizures accumulated since initiation of testing.

In Figures 1, 2 and 3, a staircase is plotted; for practice, however, the oblique line, as drawn in Figure 4, may be preferred.

Interpretation.—The position of the last point on the seizure line in relation to the boundary lines is examined after each plot. If no boundary line is crossed, plotting is continued. As soon as a boundary line is crossed, the physician is notified. In the latter case, and within the limitations of each of the tests, one may make one of the following decisions:

(a) If the lower boundary line is crossed, one may conclude that there was a significant reduction in the patient's seizure incidence (as compared to the pre-test period).

(b) If the upper boundary line is crossed, one may conclude that there was no significant reduction in seizure incidence (as compared to the pre-test period).

As compared to an intuitive appraisal of the corresponding raw incidence data, such a test decision has a reduced chance of error. But the limitations of the test decision also must be emphasized. First, one must be content with the simple *yes* or *no* answer, for which the test was constructed (one does not obtain quantitative information as to the extent of change, if any).[15] Second, the test decision is based upon the behavior of a single variable.[8] Even though in certain cases of epilepsy the seizure incidence change might be a prominent variable, clinical decisions will depend heavily on other considerations as well. Finally, one must consider possible variations in seizure incidence that are coincident with a treatment change but that are not related to it, before one decides sequentially that a given treatment is better than another. But irrespective of these limitations and including the small percentage of erroneous decisions the test meets a real need since

it fulfills a monitoring function by focusing attention upon the patient. One may re-examine the patient at times of test decision, rather than solely at arbitrary intervals (other things being comparable). The clinical decision may justifiably be in discord with the test result; even so, testing may have served an important monitoring function.

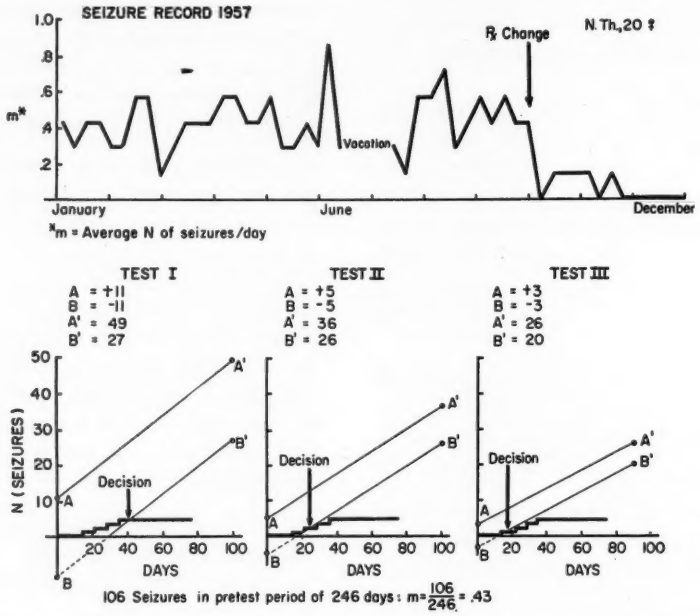

Fig. 2. Comparison of three sequential tests, applied at start of an apparently successful medication change.

Illustrative Examples.—In each of the figures, seizure data from a given patient are shown on top, with the time of medication change indicated by arrows. The tests deal with the significance of variations in seizure incidence during the period following the arrow (on top of the figures).

For comparison, in Figures 1 and 2, all three tests are applied to the same data. In Figures 3 and 4, Test II only is used. In the problem case of Figure 3, two different pre-test periods served for computing *m;* one of the computations obviously is invalid, since the requisite of superficial randomness was violated by pooling incidences during dissimilar periods (see below). In Figure 4, different medication changes are tested for their effectiveness in the same patient.

Test results are given in the bottom halves of the figures, arrows indicating the time when a test-decision was reached. In each case, the seizure line is continued after it has crossed the boundary line, to show that recrossing did not occur. In all cases, the test was applied retrospectively. For sequential testing in practice (which should be "prospective") *plotting must not be continued beyond the point of crossing.* Testing is completed when a boundary line is crossed; the physician should then be notified immediately.

Speed of Tests.—In comparison to Test II, Test III is faster in yielding decisions and Test I slower. In the case of Figure 1, for instance, Test III yielded a decision in less than twenty days, while Test II took about thirty days and Test I about seventy days (see arrows). In this case, the tests ascertained that the medication change was not followed by a significant reduction in seizure incidence since the seizure line crossed the upper boundary.

In the case of Figure 2, the tests ascertained a significant reduction in seizure incidence. Test III did so within 20 days, Test II took over 20 days and Test I almost 40 days.

In return for quicker decisions by Test III, one accepts a lesser degree of accuracy when seizure reduction is relatively small. The reverse holds true for Test I, while Test II is intermediate with respect to speed and accuracy. These differences among tests were ascertained in a retrospective study of 100 cases.

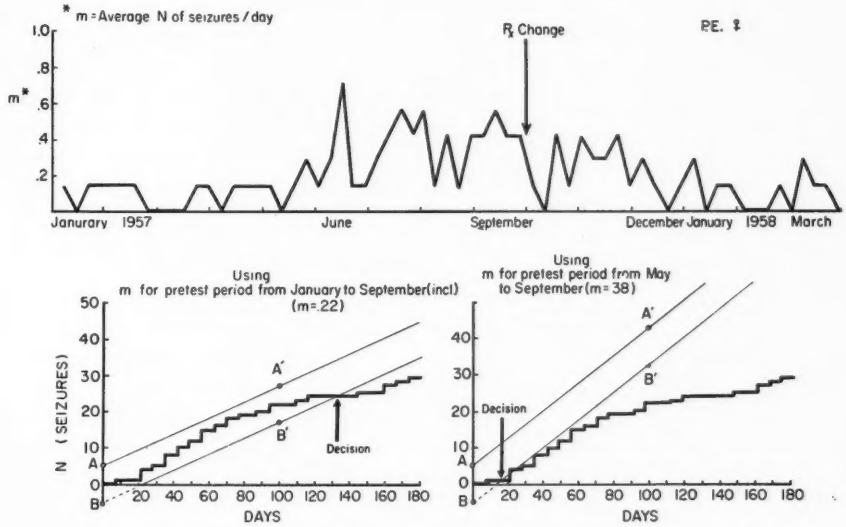

Fig. 3. Choice of an appropriate pre-test period—a critical and often difficult consideration in sequential testing (see text).

The advantages and disadvantages of the three tests should be weighed against one another, in each application. Test III, for instance, may be used in new cases, when a greater control of seizures is the aim of treatment and when frequent changes in therapy are warranted. Conversely, in cases remaining refractory in spite of many changes in medication, Test I may serve to ascertain a relatively small degree of reduction; in such cases it may not matter that the decision requires more time.

In most cases, Test II will be practical since it yields a decision regarding a substantial reduction in seizure incidence and since it usually does so within a reasonable time period.

Some Difficulties.—Irrespective of the test used, the selection of an appropriate pre-test period remains a critical problem. Superficially, the longer the pre-test period, the better. But significant changes in seizure incidence may occur quite independently from a change in medication or even in the absence of medication change. In the case of Figure 3, for instance, seizure incidence was higher after June 1957 than before. The decision of Test II was the same, whether the pre-test incidence was computed on the basis of the period from June to September or on the basis of the period from January to September. It was only the time necessary for test decision that varied as a function of the period used for computing m (the pre-test period incidence). This case illustrates some of the difficulties involved.

From a statistical viewpoint, it is not legitimate to pool seizure incidences before and after June, if as is the case, these incidences are significantly different. From a clinical viewpoint as well, this pooling cannot be sanctioned, since the mechanisms underlying any disease are subject to change in terms of progression or regression.

Moreover, fluctuations in seizure incidence such as those shown in Figure 3 (top) might be brought about by as yet questionable seasonal or other variations, not related to the medication change tested. From the viewpoint of practice, it seems debatable, whether in such cases repeated sequential tests on various therapies are worthy of application. Even if deemed worthy, sequential tests may be applied only if the occurrence of seizures

is superficially random, at least for a period of reasonable length.

Another difficulty may arise from a possible (untested) change in clinical seizure type after a change in medication. This will be no problem, however, if the different seizure types are separately recorded and plotted.

Finally, the occurrence of status epilepticus may be cited as a clinical circumstance necessitating immediate therapy adjustment, irrespective of test result.

What Sequential Testing Cannot Do.—A reduction in seizure incidence may be associated with behavior changes including sedation, with rash, jaundice or other side effects varying in kind and severity. An overall evaluation of the patient therefore remains indispensable, whether or not one tests sequentially. One may not exclusively rely on a statistical analysis of seizure counts in the care of convulsive disorders just as one does not rely solely on blood counts in treating certain blood dyscrasias. The sequential test may prove to be an important additional aid, but it is not intended to replace any of the standard professional activities.

What Sequential Testing May Do.—The advantages of sequential testing are twofold. Test decisions serve as monitor and they replace less objective decisions as to seizure incidence changes.

In a busy practice or in the often under-staffed institution, monitoring may prove to be as important as is decision-helping. In most hospitals, an important requisite for testing, namely the recording of seizures, is routine. The test allows much better use of such records, with minimal additional clerical work. This is illustrated with an institutional case in Figure 4, but the conclusions may also apply to patients treated in general practice.

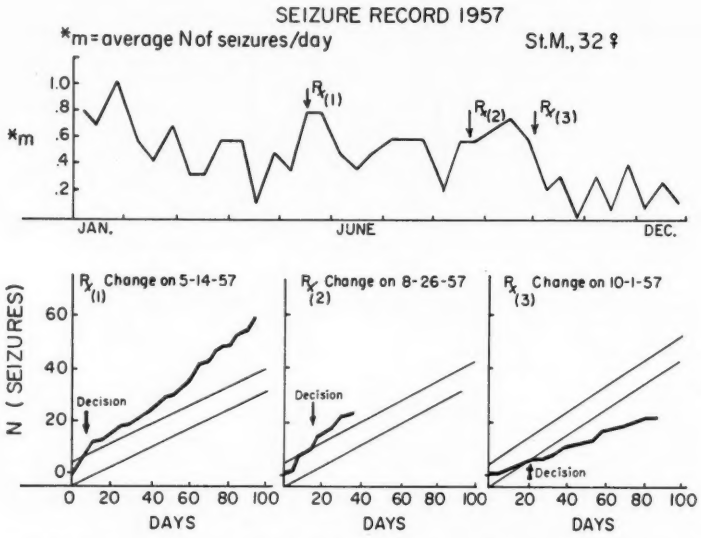

Fig. 4. A patient will not be left on a given medication for too long, if record is tested sequentially. Compare periods elapsed between successive intuitive changes in medication (top) with the shorter periods (bottom) required if sequential testing would have been applied (see text).

Following a first medication change tested in Figure 4, the seizure line crossed the upper boundary of Test II on the sixth day (that of Test III, on the third day and that of Test I, on the sixty-first day; these latter test results are not shown). The test decision (if it had been available) may have monitored a treatment change. The attending physician, however, did not intuitively change medication until over three months had elapsed. In other words, a change in medication might have been made much earlier if sequential testing had been carried out at the time of the medication change (rather than retrospectively, as was done in the case of Figure 4).

Following the second change of medication in

the case of Figure 4, the upper boundary of Test II was crossed after nine days (that of Test III after seven days, while Test I had not reached a decision until the thirty-first day; these latter test results are not shown). By thirty-six days following the second change in medication, it had become clinically obvious that no improvement had occurred and a third change in medication was instituted. Thereafter seizure incidence dropped promptly, and the seizure line crossed the lower boundary of Test II after seventeen days (that of Test III, after seven days and that of Test I after over thirty days; the latter test results are not shown).

Conclusions and Summary

Sequential testing may be used, i.a., in the care of certain (but not all) patients with convulsive disorders. Such tests serve as monitors of the presence or absence of a reduction in seizure incidence. Seizure frequency data need not be examined only at intuitively chosen, usually long intervals. The check for the presence or absence of changes in seizure incidence may be made frequently, if necessary daily, by means of sequential testing. Such testing is so simply done and interpreted that its day-to-day performance may be delegated to non-professional personnel. Thus, the test is automatic, as far as the physician is concerned.

The procedure is graphical; in simplified forms it may be set up with minimal arithmetic and thereafter it is carried out with no computation.

Three tests are described; as their speed in yielding decisions increases, their accuracy suffers (particularly in detecting relatively small reductions of seizure incidence).

The tests have limitations and they are not always applicable. When pertinent, however, sequential testing may provide more objective, rather than merely intuitive, decisions as to the significance of seizure incidence changes. The risk of erroneous decisions is largely predetermined and reduced to practical limits.

Test results help particularly in evaluating the efficiency of anticonvulsant medication; they may prevent given medication from being tried for too short a period or for too long a period.

Sequential tests must not replace any of the standard medical services, although they may appreciably aid treatment, as simple, graphic, monitoring and decision-helping tools.

Ocular Palsy in Temporal Arteritis

Medical Progress

Part I

DURING the past fifteen years, temporal arteritis has come to be recognized as a not uncommon affliction of the elderly. Its better-known manifestations include: severe headache, prominent, firm (often pulseless) extracranial arteries, pain on chewing, aching in muscles and joints, chilliness, impaired vigor, anorexia, loss of weight, low-grade fever, and an elevated sedimentation rate. The otherwise benign course of the illness is seriously complicated in some 50 per cent of cases by the occurrence of permanent, complete or partial, blindness in one or both eyes—caused, in all probability by inflammatory involvement of the central retinal arteries or the arteries supplying the optic nerves.

Recently, two cases of biopsy-proved temporal arteritis have been encountered at the Massachusetts General Hospital in which the opening phase of the illness was strikingly characterized by diplopia, ptosis and ocular palsies, and since headache was not a prominent feature in either case, the correct diagnosis was suggested only when marked impairment of vision supervened. The chief aim in presenting these two cases is to draw attention to the occurrence of ocular motor disturbances in temporal arteritis; however, in Case 1, there were additional features of interest—transient diabetes insipidus, pharyngeal edema, dysphagia, trismus, conjunctival edema, and periorbital swelling.

In making this report, the author has taken the occasion to review the general cerebral manifestations, not only of temporal arteritis, but also of the other more common types of systemic arteritis; in addition, a classification and description of the arteritides will be presented in outline form.

Case Histories

Case 1.—C.V. (966810) man, aged seventy-three; admitted April 18, 1957, discharged May 23, 1957.

Summary.—Over a period of three weeks, the patient successively developed fatigue, weakness, anorexia, headache, sore throat, and severe puffiness of the eyes and face. After admission, temperature ranged from 101 to 103° F. On the fourth hospital day, bilateral sixth nerve palsy appeared and also some involvement of the left third nerve. These improved rapidly but on the twelfth

To be published in three parts.

C. MILLER FISHER, M.D.
Boston, Massachusetts

From the Neurology Service, Massachusetts General Hospital, and the Department of Neurology, Harvard Medical School. This work was supported in part by United States Public Health Service, Grant 5993-5.

Dr. Fisher is Neurologist, Massachusetts General Hospital and Assistant Clinical Professor of Neurology, Harvard Medical School.

hospital day, the patient became totally blind in the left eye, and on the thirteenth day, partially blind in the right eye. Finally, severe diabetes insipidus occurred from the sixteenth to the twenty-second day. Biopsy of the left temporal artery showed a subacute arteritic process with lymphocytes, other mononuclear cells and many giant cells.

On admission, the patient complained of fatigue, weakness, anorexia, headache, sore throat, and puffiness of the eyes and face. On a background of extremely good health, he had first noted fatigue and weakness two months before admission. Three weeks prior to admission, fatigue was accentuated and severe anorexia developed. At the same time, a mild nonproductive cough appeared. Two weeks before admission, fluid collected in the olecranon bursa of the left elbow and 8 cc. of amber fluid were removed. Five days before admission, sore throat and difficulty in swallowing were noted. Headache began at this time and was chiefly occipital at first but later moved to the frontal region as well. Four days prior to admission, whitish exudate was found on the throat and penicillin therapy was given without benefit. Therapy was changed to Mysteclin V. The patient may have had a brief syncopal attack at this time. Two days before admission, the temperature rose to 100.4°. On the day of admission, the patient's face appeared puffy and both eyes "watered." There had been no illnesses of importance in the past and the patient was not predisposed to allergies. He neither smoked nor drank to excess.

Examination.—Temperature 101.6° F., pulse 100, respirations 22, blood pressure 160/90 mm. Hg. The patient appeared moderately ill and was extremely slow and feeble.

Severe conjunctival edema and mild periorbital swelling were present bilaterally, along with some redness of the tissues around the left eye. Visual acuity was normal and the visual fields were full. The pupils were equal and reacted to light. The extraocular movements were full without nystagmus. The fundi were not remarkable. The pharyngeal mucous membrane was swollen and slightly reddened but free of exudate. The teeth were carious and gingival pus could be expressed. Moderate trismus was noted and on opening the jaw, the upper and lower teeth could be separated only 3 cm. The salivary duct ostia were normal. The heart, lungs, abdomen, extremities and neurologic findings were not remarkable.

At the time of admission, an exact diagnosis could not be made but an infective or allergic process was suspected. The possibility of cavernous sinus thrombosis was also considered.

Laboratory.—Urinalysis shortly after admission was normal. An examination of the blood showed: hemoglobin 13.0 gm.; leukocytes 18,200 per cu. mm.; differential count—polymorphonuclear leukocytes 91 (band forms 1), small lymphocytes 4, monocytes 2, eosinophils 2;

platelets normal. A serological test for syphilis was negative. X-rays of the chest, paranasal sinuses, skull and colon were normal. Dental x-rays showed radiolucency around several teeth. A throat culture was sterile. A culture of the gingival pus showed moderate *Staphylococcus aureus* and alpha streptococcus. An electrocardiogram was within normal limits. Blood chemistry: nonprotein nitrogen 26 mg. per cent, blood sugar 121 mg. per cent, and sodium 138, potassium 5.6, chloride 92 and carbon dioxide 34, each in Meq. per liter.

Course.—During the first ten days in the hospital, the patient's general condition remained about the same, although the conjunctival and periorbital edema worsened slightly. The temperature ranged from 101 to 103° F. and the pulse was unduly rapid.

The patient vomited several times in the first twenty-four hours. During the next three days, headache, sore throat and cough abated to some extent but because of the persistence of fever and malaise, therapy with chloromycetin and erythromycin was started. On the fourth hospital day, impairment of ocular movements was reported. On examination, the temperature was 103° F. There was less periorbital swelling than on admission but the conjunctival edema had increased. The pupils were round, regular and equal at 2.5 mm., and reacted well to light. Boggy edema involved chiefly the lower half of each globe. On the left side there was no lateral movement of the eye beyond the midline, while on the right, abduction was limited to one quarter of the normal excursion. The left eye adducted incompletely and excursion downward was probably limited. Testing for diplopia with a red glass resulted in inaccurate responses. The clinical impression was involvement of the sixth nerve bilaterally and of the third nerve on the left.

Neurologic examination revealed no other definite evidence of involvement of the nervous system. The patient appeared to be normal mentally. There was no paralysis or numbness of the limbs. The tendon reflexes were normal and equal on the two sides. There were no meningeal signs and a cranial bruit could not be heard. The left nasolabial fold was questionably flattened and the gait may have been slightly wide-based. A lumbar puncture gave the following results: initial pressure 210 mm.; the cerebrospinal fluid was clear and colorless and contained 2 lymphocytes per cu. mm.; the total protein was 25 mg. per cent. The administration of pyribenzamine and adrenalin was of no avail. The trichinella antigen skin test was negative. Widal and Brucella tests were negative. Prostigmin did not improve the oculomotor power. Because of the earlier history of sore throat, 20,000 units of diphtheria antitoxin were given as a safety measure. Several urinalyses were normal.

There was little change for the next four days but on the eighth hospital day, abduction movements of the eyes were greatly improved, being almost full on the left. Improvement continued but on the twelfth hospital day, vision became severely impaired in the left eye and only form and motion could be discerned. There was relative sparing of vision in the upper nasal quadrant. Visual acuity in the right eye was perfect. There was mild but definite papilledema in the left eye, the right disc was normal. The left pupil was 3.5 mm. and failed to react to light directly but consensual reaction was preserved. The right pupil was 5 mm. and reacted well to light and on convergence. Lateral gaze was slightly limited bilaterally; upward gaze was questionably restricted. There was slight ptosis on the left. Again a suggestion of left facial weakness was noted. The remainder of the neurologic examination was not remarkable.

By the following day, visual acuity had become impaired in the right eye also (visual acuity 20/100), and perception of light in the left eye was now questionable. The presence of papilledema in the left eye was confirmed and definite pallor of the disc was described. The left pupil was still *miotic* and fixed to light directly but not consensually. Lateral and upward movements of the eyes were considered normal. The diastolic pressure in the central retinal artery was 22 arbitrary units, bilaterally. The temporal arteries were noted to be firm but not tender, and pulsations could be felt. The patient had had no headache since the second hospital day. On the fourteenth hospital day, vision was limited to the nasal field of the right eye, the left eye being totally blind. Ptosis and miosis on the left side continued.

Biopsy of the left temporal artery showed a moderately severe arteritic process with lymphocytes, other mononuclear cells and many giant cells lying in the media. A biopsy of skeletal muscle was not remarkable. Meticorten (60 mg. per day) was started and within a day or two the patient's general condition improved remarkably. The temperature fell to normal and appetite returned. The periorbital and conjunctival swelling subsided. There was little or no recovery of vision.

Two days after starting meticorten (sixteenth hospital day), the patient reported increased thirst and polyuria, and in twenty-four hours, the urinary output was 5000 cc. On the following day, the output was about the same and the specific gravity of the urine varied from 1.004 to 1.008. Plans were made to investigate, in detail, the patient's diabetes insipidus but due to his distress, a posterior pituitary antidiuretic preparation was given with complete but temporary relief. Twenty-four hours later, symptoms recurred but within another twenty-four hours, a "spontaneous" cure had occurred—the specific gravity climbing steadily from 1.005 to 1.012, 1.015, and finally 1.025.

Examination of the eyes on the sixteenth hospital day showed no change in the visual acuity, the left pupil continued to be small and fixed, and there was a left ptosis. The left corner of the mouth drooped. Meticorten was continued at 60 mg. per day. On the twenty-third hospital day, blindness was still total in the left eye, while in the right eye vision was limited to the upper nasal quadrant. The patient could read one-inch letters. He could see extremely well at a distance and could make his way around the ward satisfactorily. Orbital edema had long since cleared. The right optic disc was pale nasally; the left disc was still indistinct. The retinal vessels were healthy in appearance. The pupils were equal; the right reacted to light directly but not consensually, the left reacted only consensually. The extraocular movements were full in all directions and there was no nystagmus. The right temporal artery was prominent and firm but not tender. Pulsation was

scarcely perceptible. Facial sensation was normal. The throat and buccal mucosa was not remarkable. Neurologic examination was normal except as described above. The muscles of the limbs were not tender. There was no skin rash.

During the following twelve months, there was no appreciable change in vision but the patient's general health remained extremely satisfactory. Meticorten therapy was maintained for one year.

Comment.—In this case, the diagnosis of temporal arteritis seemed to be unquestioned on the basis of the biopsy of the temporal artery and the clinical course, especially the occurrence of severe impairment of vision bilaterally.

In regard to the involvement of orbital and intracranial structures, the following points should be noted: (1) Both sixth nerves were involved, and probably the left third nerve also. The oculomotor paralysis was transient and had greatly improved within four days and had cleared completely in six or seven days. Ptosis on the left side was noted by several observers. (2) The occurrence of severe damage to the left optic nerve followed within hours by signs of involvement of the right optic nerve, particularly its nasal half (temporal field deficit), suggested that the lesions might have been situated in the region of the optic chiasm. However, the presence of papilledema (albeit mild) in the left eye would favor a retrobulbar location of the disease process; furthermore, the diastolic pressures in the central retinal arteries, though equal, were probably low. There was virtually no late improvement in vision. (3) The occurrence of diabetes insipidus has not been previously recorded in temporal arteritis. It is postulated that the hypothalamus was involved adjacent to the optic chiasm. The duration of the diabetes insipidus was brief (six days). (4) One of the outstanding features in this case was severe periorbital and conjunctival swelling which at one time was of such a degree as to cause more than one consultant to attribute to it the bilateral limitation of abduction of the eyes. Although the picture resembled orbital cellulitis or cavernous sinus thrombosis, there was only very slight associated redness of the tissues and no venous distention or proptosis. Sore throat, dysphagia and trismus are uncommon complaints in temporal arteritis.

Headache was not a prominent complaint; furthermore, the temporal arteries pulsated well and were not tender. The arteries, however, were firmer than normal and it might be pointed out that in the healthy state, the walls of the temporal artery are almost impalpable when felt by the examining finger. Skilful palpation of these vessels will almost invariably enable the physician to determine the presence or absence of arteritis.

Case 2.—D. S. (959156) man, aged eighty-four; admitted February 12, 1957, discharged March 19, 1957.

Summary.—Progressive course over a period of six weeks of headache, ptosis, diplopia, bilateral third nerve deficit, blindness in left eye, and partial blindness in right eye. Biopsy showed giant cell arteritis of the left temporal artery. Symptomatic relief on Meticorten therapy. Vision failed to improve.

The patient's memory had been impaired for one year and for this reason, the details of the history were not as accurately determined as might be desired. About six weeks before admission, loss of vigor was noted, appetite failed, and mild headache appeared. Twenty days before admission, relatively complete left ptosis occurred and the left eye deviated laterally and upward. The ptosis cleared in about three days and the patient then complained of diplopia. Nine days before admission, vision failed in the left eye, and at that time examination by a neurologist showed evidence of involvement of the left third and fourth nerves. At no time was headache a prominent complaint. Within a few days, the left eye had become almost totally blind and vision in the right eye began to fail. On the day prior to admission, examination by Dr. M. P. Easton showed a visual acuity of 20/200 in the right eye and only light perception in the left. The left eye was divergent with weakness of medial rectus and inferior rectus, and questionable ptosis of the upper lid. There was weakness of the medial rectus of the right eye. There were no associated neurologic complaints such as dizziness, paralysis, numbness, ataxia, or speech disturbance.

The patient had had no previous illnesses of significance. There was no history of illness or arthritis. He had not been taking medicaments and he neither smoked nor drank.

Examination.—The patient, a vigorous elderly gentleman, was almost blind and, in addition, had severe impairment of recent memory. He did not appear ill although weight loss had been reported. He was extremely alert and cooperative. Although he had never complained of headache, when it was suggested that he had had no headache, he exclaimed, "My God, it's terrible, that's why I'm here. It's all over, but worse up here" (on pate). When asked to put his finger on the point of maximum headache, he placed it directly over the anterior branch of the right superficial temporal artery, 1.5 in. behind the outer corner of the eye. The patient spoke clearly and used language perfectly. There were no significant neurologic abnormalities except those involving the visuo-oculomotor apparatus.

Vision in the right eye was 5/50 (Snellen) while on the left, only very bright light was appreciated. In the right eye there was a temporal field defect, while nasally the visual field was greatly constricted, especially inferiorly. He could slowly read two-inch headlines but tended to hold the newspaper to his left.

There was bilateral ptosis of moderate degree. The pupils were equal at about 5 mm. The right pupil was round, the left oval. Neither pupil reacted to the brightest light but both reacted well on convergence. The failure to react to light was attributed (probably wrongly) to the recent use of mydriatics. On gaze forward, the patient sometimes fixed the object with the right eye and the left eye deviated laterally about one quarter of the normal lateral range, while at other times, fixation was with the left eye and the right eye deviated laterally. The ocular movements were easily performed but on conjugate lateral gaze, adduction of each eye was impaired by at least one quarter of its normal medial excursion. Gaze up and down was normal. There was no nystagmus. There was no orbital edema.

On examination of the fundi, the discs were somewhat yellowish but clearly outlined. One observer thought both discs were abnormally pale, but several others judged them to be non-atrophic. The vessels were perhaps attenuated and there was mild displacement of the veins by the arteries, but no occlusions were evident. There were no hemorrhages or exudates. The diastolic pressure in the central retinal artery on the right was 90 units; the left could not be accurately measured. The intraocular pressure was normal bilaterally.

The temporal arteries were conspicuous but not more so than in many elderly persons, and on both sides there were good pulsations. However, the arteries were firmer than normal. Heavy pressure combined with rolling the vessels under the finger produced only mild distress. The internal carotid pulsations were strong bilaterally and there was no intracranial or cervical bruit.

There was no facial weakness. Hearing was impaired bilaterally. On the Weber test, the sound of the fork was not lateralized. The tongue protruded in the midline. There was no stiffness of the neck. Motor power, coordination, and rapid alternating movements were normal in the limbs. Sensation was normal for pin prick, vibration, touch, position, and temperature. The tendon reflexes were sluggish but equal on the two sides. The plantar reflexes were flexor. The gait was not remarkable.

There was mild cardiac enlargement and a systolic precordial murmur was heard. The blood pressure was 200/110. Pulsation in the right posterior tibial and left dorsal pedal arteries was absent. The lungs were clear. The abdomen was negative. There was no skin rash or muscle tenderness. The temperature and pulse were normal.

Laboratory.—Urinalysis—no albumin or sugar, one erythrocyte, two leukocytes. Blood count—leukocytes 7,700 (polymorphonuclears 63, small lymphocytes 20, monocytes 11, eosinophils 4, basophils 2), platelets normal. Hemoglobin 11.4 gm. Blood sedimentation rate 56 mm. in one hour. The blood chemistry was as follows: nonprotein nitrogen 28, fasting blood sugar 89, cholesterol 151, each in mg. per cent; total protein 6.8, albumin 4.2, globulin 2.6 each in gm. per cent (A/G ratio 1.6); prothrombin activity 47 per cent.

Cerebrospinal fluid—initial pressure 80, crystal clear fluid, no cells, total protein 76 mg. per cent, colloidal gold 1111222110, Wassermann negative. X-rays: Chest—lungs clear, prominence of left ventricle; skull—no significant abnormality. Electrocardiogram: Nodal rhythm with occasional auricular and ventricular premature beats; borderline T wave changes. Isotopic test for cerebral tumor was negative. Electroencephalogram was within normal limits.

Course.—Because of the oculomotor paresis and the apparent absence of headache, the possibility that temporal arteritis was present did not come to mind immediately. However, when the presence of temporal headache became more definite on repeated questioning and the sedimentation rate proved to be elevated, a therapeutic trial with Meticorten was begun on the second hospital day, despite the patient's afebrile course. Within twenty-four hours, the patient's disposition improved, his head felt better, and appetite returned. Vision did not deteriorate further. On the seventh hospital day, biopsy of the left temporal artery showed chronic inflammation of the vessel wall. The media and adventitia contained a moderately heavy infiltration of lymphocytes and monocytes with occasional giant cells and polymorphonuclear leukocytes.

There was practically no recovery of visual function. Over a period of three weeks, it became possible for the patient to read one-inch headlines slowly with the right eye. Only bright light could be appreciated in the left eye. On about the fourteenth hospital day, the patient reported that for about fifteen minutes, vision improved dramatically so that he was able to see faces, furniture, and furnishings. There were no further such episodes. Because of the severe loss of vision in the left eye, coupled with a temporal field loss in the right eye, an arteritic lesion of the optic chiasm was suspected, and signs of damage to the adjacent hypothalmic region were watched for but none was detected (see *Case 1*). The pressures in the central retinal arteries were normal: right, 80/135, 85/135; left, 90/135, 92/137 (arbitrary units). By the fourteenth hospital day, both optic discs were becoming distinctly pale, and in the following months they became chalk-white. The retinal vessels remained unchanged. Useful vision was limited to the upper nasal field of the right eye.

The pupils continued to show no reaction to light but a good response on convergence. Twenty-four days after admission, the right pupil measured 5 mm., the left 3 mm. and both reacted slightly to light. The lids drooped less after approximately one week in the hospital. The extraocular movements were recorded as being full twenty-two days after admission, but it is likely that recovery in this respect had occurred earlier. Examination eleven months later showed no essential change in the visuo-oculomotor status. The right pupil measured 6 mm., the left 4 mm. Neither reacted to light but upon convergence there was a brisk full constriction. Both discs were extremely pale. The central retinal artery pressure on the right was judged to be normal by digital pressure.

Comment.—This was, actually, the first case encountered at the Massachusetts General Hospital in which temporal arteritis was associated with an

oculomotor paresis. Recovery from this particular deficit was fairly rapid and complete. The left ptosis, which was severe originally, improved greatly in a few days. The remainder of the third nerve deficit on the left improved further in the ten days prior to admission, and the bilateral limitation of adduction cleared in the week or two after admission. The pupils remained relatively unresponsive to light directly and consensually despite the persistence of a sector of vision in the right eye. There was no pain within the orbit. The patient's failure to complain spontaneously of headache, the lack of tenderness or enlargement of the temporal arteries, the persistence of pulsation in the vessels, the afebrile course, and the mildness of the general systemic disturbance are additional points worthy of note.

Discussion

A. Summary of the Literature Pertaining to Ocular Palsy

While British and French authors have referred to ocular palsy as a manifestation of temporal arteritis, the American literature makes only passing mention of it. Bruce[1] (1950) in his summary of the literature did not allude to cases in which diplopia and ptosis were features; however he was mainly interested in the incidence of blindness in the reported cases of temporal arteritis, which he found to be about 40 per cent.

Horton and Magath[2] (1938) noted diplopia in one of the seven cases they reported in 1938. In Case 2 of Dick and Freeman[3] (1940) the patient, a woman aged seventy-six, first had headaches for some five months followed by blurring of vision. Diplopia occurred for one week. Examination seven months after the onset revealed sluggish extraocular movements, poor vision in the right eye, and large firm, tortuous temporal arteries. In Murphy's[4] (1941) case, a woman aged seventy-one, experienced headache, swelling of the left jaw, painful chewing, and drooping of the left eyelid. Vision was apparently not affected (visual acuity had been impaired in the right eye for many years). Biopsy of the temporal artery showed a chronic inflammatory process containing giant cells. Ocular examination was normal.

Case 1 of Broch and Ytrehus[5] (1946) was a man aged sixty-nine who, following a period of headache and tenderness of the scalp, developed diplopia and ptosis, the latter appearing first on the left and two or three days later on the right. The temporal arteries were enlarged and pulseless. Examination showed an alternating divergent strabismus with diplopia in all directions. Ptosis was present on the right. Three weeks later slight ptosis was still present and eye movements were restricted. The ocular signs slowly improved but generalized pains appeared and the patient died from systemic effects approximately six months after the appearance of the ocular manifestations. The diagnosis of temporal arteritis, although not biopsy-proved, was almost certainly correct.

Cooke and his associates[6] (1946) reviewed the clinical findings in seven of their own cases of temporal arteritis and in thirty cases recorded in the literature. They found eighteen cases in which there was a visual disorder. These included diplopia (six cases), weakness of the extraocular movements (two cases), and ptosis (two cases). They suggested that the disease process must affect the arterial supply of the optic and ocular motor nerves in varying degree. In their Case 1, a man aged sixty-six, after experiencing headache, pains in the arms and legs, and tiredness for two months, found, on retiring one evening, that both eyes closed and he could not open them voluntarily. If he raised his eyelids with his fingers, he found he could see normally with the right eye but the left appeared as though there were a "black stream" falling over that eye. The bilateral ptosis lasted only twenty-four hours. One month later, he became totally blind in the left eye. Biopsy of the temporal artery showed a mild periarteritis.

In Case 2, a woman aged sixty-six, three months from the onset of her illness, began to have severe headaches; three weeks later, for a period of three or four days, she noted diplopia, the right-sided image being beside and slightly above the image of the left eye. At about this time, she noticed that the sight of the right eye failed and she became totally blind in twenty-four hours. Vision in the left eye was completely lost about one month later. Fundoscopic examination showed pale discs and thin arteries of uneven caliber. There was no oculomotor disturbance. The temporal arteries were tender but owing to the presence of numerous vesicles and crusts on the scalp, an arterial biopsy was not made. The clinical picture, no doubt, justified the diagnosis of temporal arteritis.

Case 3 was that of a woman aged sixty-nine who first developed pain, stiffness, numbness and wasting of the left thigh. A short time later, the right

thigh was similarly affected. Two weeks later, pain began in the right arm and the diagnosis of right axillary vein thrombosis was made. The left arm became similarly affected. Eight months from the onset, the patient began to have severe headache and ten days later, diplopia occurred for two days. Shortly thereafter, bilateral total blindness was precipitated. The discs were swollen and pale; the arteries appeared normal. The cranial nerves were normal, as was the remainder of the neurologic examination. One year later, she was still blind, her mental powers were impaired, and there was generalized muscular weakness. A biopsy of both temporal arteries showed a chronic destructive arteritis with multinucleated giant cells. The patient died two-and-a-half years after the onset of her illness and pathologic examination showed localized areas of inflammation affecting the arch of the aorta, the left subclavian artery, the distal aorta, and both femoral arteries. At these sites, the arterial wall was damaged to a variable degree; there was an infiltration of chronic inflammatory cells, including giant cells. The eyes were apparently not examined.

Case 6 was that of a woman aged seventy-three years who, after having had generalized muscle pains, loss of appetite and easy fatigability for eleven months, followed by headaches for five months, developed double vision lasting five minutes. Two days later she appreciated that she was blind in the right eye and within a few days the left eye also became sightless. Examination showed pale discs. The oculomotor function was normal. Biopsy of a temporal artery showed a giant cell type of chronic arteritis. The patient died fourteen months after the onset of her illness and pathologic examination showed marked softening of both optic nerves. In the aorta there were foci of infiltration of inflammatory cells of the media and adventitia with destruction of elastic tissue and muscle fibers. The superior mesenteric artery showed a similar inflammatory reaction, as did the right femoral artery. Both retinal arteries were equally affected. The lumen was obliterated by cellular fibrous tissue, obviously formed during the organization of a thrombus. The adventitia and media were infiltrated by lymphoyctes and plasma cells, and the internal elastic lamina was fragmented and calcified. A few giant cells were engaged in phagocytosis of these calcified fragments. There was no arteritis of the intracranial vessels.

Case 3 of Crosby and Wadsworth[7] (1948) was a seventy-nine-year-old man who, following sixteen weeks of headache, was admitted to the hospital because of sudden blindness in the right eye. Five weeks before admission, he had noted occasional episodes of blurred vision, and ten days before, he had had diplopia. Oculomotor examination was apparently normal.

Dick[8] (1948) described the case of a man, aged sixty-nine, who for one year had vague aching in the joints. Headache then appeared along with a "hard vein" in the left temple. Shortly thereafter, urinary retention occurred. Five weeks later, the patient became drowsy and confused. This lasted fourteen days during which period slight bilateral ptosis and weakness of conjugate upward deviation of the eyes appeared for one day. Biopsy of a temporal artery revealed the typical picture of temporal arteritis. In this case, it is not easy to interpret the oculomotor signs in view of the mental change which might point to involvement of the upper brain stem and in the absence of any other signs of orbital involvement.

Oculomotor impairment was described in more detail by Benard and his co-workers[9] (1949) whose patient, a woman aged seventy-seven, was admitted to the hospital because of headache, malaise and double vision. On examination the right globe appeared exophthalmic and the sixth nerve was totally paralyzed, the third nerve being partially paralyzed. Elevation of the lid was normal. The right pupil was slightly larger than the left. The fundus oculi showed narrowed vessels and traces of a recent peripapillary hemorrhage but vision was normal. Five weeks later, the patient suddenly became blind in the right eye. The temporal arteries were enlarged and tender, and biopsy showed a chronic inflammatory process including giant cells. The oculomotor palsies improved slowly and recovery was incomplete.

In Case 4 of Bessière and Julien[10] (1951), the patient was blind in the right eye and gave a history of a temporary paralysis of the right sixth nerve ten months before the onset of headache and the other symptoms of temporal arteritis. In view of the long interval, one might conclude that the relation of the ocular palsy to the arteritic process was not proved.

The patient of Cardell and Hanley[11] (1951) noted diplopia for four days before blindness occurred in one eye. On ocular examination two

days later, no ocular motor deficit was found.

Case 8 of Parsons-Smith[12] (1952) was a man, aged sixty-nine, who gave a four-week history of diplopia which was found to be due to weakness of the left inferior rectus muscle. The patient had had some left-sided headache during the previous two or three months. The diplopia disappeared in about four weeks. Biopsy of an occipital artery showed a nonspecific inflammatory change in the arterial wall. Visual acuity was not affected. This case illustrates the possibility of oculomotor signs existing when visual acuity remains intact. In his Case 9, the patient, a woman, aged seventy-three, complained of severe pain in both eyes. There was a long history of visual disorder (corneal ulcers, iridectomy, and glaucoma). She had severe hypertension (255/130) and severe headache. The occipital and temporal arteries were tender. The headache and pain in the eyes subsided within six weeks. Vision was not affected. A histologic examination of the arteries was not made, and a good deal of doubt concerning the diagnosis must remain. It has been included only to signify the possibility that pain in the orbit could conceivably be a manifestation of cranial arteritis.

Case 14 of Parsons-Smith, a diabetic woman of sixty-two, developed a severe stabbing pain in her left eye followed by diplopia, ptosis, and complete paralysis of the third nerve. Visual acuity was 6/6 in the right eye, 6/9 in the left. She experienced considerable pain in the left side of the neck, and the left temporal and occiptal arteries were acutely tender. A biopsy was not made. The "arteritis" and visual symptoms cleared in about two months. In the absence of histologic evidence of arteritis, one might well have made the diagnosis of diabetic ophthalmoplegia in this case, the clinical picture being very typical. The essential lesion in diabetic ophthalmoplegia is still not known, but in a pathologic study of the vessels running to the third nerve by Dreyfuss, Hakim and Adams[13] (1957) an arteritis was not found.

TABLE I. CASES OF TEMPORAL ARTERITIS WITH OCULOMOTOR INVOLVEMENT

Author	Symptoms	Signs	Duration
1938 Horton and Magath	Diplopia	—	—
1940 Dick and Freeman			
Case 2	Diplopia	—	1 week
1941 Murphy	Left ptosis	—	—
1946 Brock and Ytrehus			
Case 1	Bilat. ptosis, diplopia	Alternating strabismus, right ptosis	Slow improvement
1946 Cooke et al			
Case 1	Bilat. ptosis	—	24 hours
Case 2	Diplopia	—	3 to 4 days
Case 3	Diplopia	—	2 days
Case 6	Diplopia	—	5 minutes
1948 Crosby and Wadsworth			
Case 3	Diplopia	—	—
1948 Dick	Bilat. ptosis	Weakness of upward gaze	One day
1949 Benard et al	Diplopia	Right 6th, right 3rd (partial)	Slow incomplete recovery
1951 Bessiere and Julien			
Case 4	—	Right 6th	—
1951 Cardell and Hanley	Diplopia	—	? 4 days
1952 Parsons-Smith			
Case 8	Diplopia	Weakness of left inferior rectus	4 weeks
Case 14 ?	Diplopia, ptosis	Left 3rd	2 months
1953 Kendall			
Case 5	Diplopia, ptosis	Right 3rd	Partial recovery in 3 months
1954 Heptinstall et al			
Case 5	Diplopia	—	Transitory
Case 14	Diplopia	—	Occasional
1958 Fisher			
Case 1	Diplopia	Bilat. 6th, ? left 3rd (ptosis)	8 days
Case 2	Ptosis, diplopia	Left 3rd, slight right 3rd	2 to 3 weeks
Case 4 ?	Diplopia	Left 6th	6 months

In Case 5 of Kendall[14] (1953), the patient complained of double vision and complete closure of the right eyelid. Examination showed a complete paralysis of the third cranial nerve. Three months later, partial paralysis persisted with a dilated fixed pupil, incomplete ptosis and defective adduction of the globe. The temporal vessels were thrombosed and tender but a biopsy was not made. Transitory diplopia was mentioned in Cases 5 and 14 of Heptinstall and his associates[15] (1954). Wagener and Hollenhorst[16] (1958) reported that twelve of their 122 cases of temporal arteritis had diplopia sometime in their course but only three showed motor limitation at the time of examination.

In another personal case *(Case 3)*, the patient experienced diplopia in the course of an illness suggestive of temporal arteritis, but biopsy of the temporal artery failed to establish that diagnosis. The patient, aged fifty-four, had been treated successfully for cervical glandular tuberculosis twenty years before and had suffered from bilateral irido-

cyclitis with corneal scarring for fifteen years. Eleven months before admission, moderately severe persistent pain began in the neck, cheek and temple on the left side and six months later on the right side. Four months before admission, a sixth nerve palsy appeared on the right side and cleared completely in three weeks. Three days before admission, the patient became blind in the left eye. Biopsy of the left superficial temporal artery was negative. Meticorten therapy was started and within twenty-four hours head pain, which had been a distressing complaint day in and day out for many months, entirely disappeared. Vision in the left eye was partially restored. The presence of head pain, diplopia and blindness and the prompt response of the head pain to Metacortin, strongly favored the diagnosis of arteritis. There was no laboratory evidence of sarcoidosis.

B. The Clinical Picture and the Underlying Pathology

Although most of the case reports are brief and convey only a partial idea of the clinical manifestations, the following picture might be formulated: Ptosis, unilateral or bilateral, is most common and to this may be added more extensive damage to the third nerve or its branches, resulting in oculomotor palsy and diplopia. The sixth nerve, on one or both sides, is involved slightly less frequently. Oculomotor impairment does not always presage visual failure but in all cases in which both conditions occurred, diplopia or ptosis preceded the onset of blindness. Recovery from the paralytic deficit is, in most instances, prompt and complete, the symptoms and signs clearing over a period varying from several hours to a few weeks. The true incidence of oculomotor involvement is probably not reflected in the reported data because cases of cranial arteritis are no longer reported unless the illness presents unusual features. Furthermore, the dramatic occurrence of blindness overshadows other ocular complaints, and when vision fails, diplopia, of course, vanishes. From the data surveyed, the incidence of oculomotor involvement in temporal arteritis is estimated to be approximately 15 per cent.

The finding of diplopia in Case 8 of Parsons-Smith[12] and of ptosis in Murphy's[4] case, in the absence of any impairment of visual acuity, indicates that oculomotor palsy may occasionally be the only neurologic complication of temporal arteritis. A patient in whom a similar situation may have existed, has recently been seen by the author in consultation with Dr. J. Michelsen.

Case 4. F. B. (992646) man, aged seventy-four. The patient's only complaint was diplopia which had begun ten months previously and was slowly improving. Eleven months before, the patient, having been in excellent health, began to have severe pain in the temporal regions bilaterally and a little later in the upper jaw and zygomatic regions bilaterally. The pain persisted for about four weeks and as it subsided, diplopia appeared and persisted throughout the intervening ten months. On examination, there was obviously a partial paralysis of the left sixth nerve. The remainder of the general and neurologic examination was within normal limits save for the fact that no pulsation could be felt in the superficial temporal arteries, although pulsations elsewhere were excellent. The sedimentation rate was 42 mm. in one hour. As the patient was in no discomfort and the sixth nerve palsy was improving, biopsy of the temporal artery was not carried out. Admittedly in this case the evidence for an arteritis is tenuous, and the diagnosis is put forward with reserve.

The pathologic process underlying oculomotor involvement, although virtually unstudied, is presumably an arteritic involvement of the vasa nervorum supplying the ocular motor nerves, rather than primarily a myositis. In Cardell and Hanley's[11] case, several of the posterior ciliary arteries (which supply the ocular motor nerves) showed a marked intimal thickening and a diffuse cellular infiltration of all coats of the vessel wall with macrophages, lympocytes and a few plasma cells. In one artery, an occasional giant cell was seen. On the grounds of proximity, it might be anticipated that the process causing the oculomotor palsy is analagous to that responsible for blindness. In all, some seven histologic examinations have been made of the optic nerves and their vessels of supply in cases of blindness. In Cardell and Hanley's case, the lumen of the right ophthalmic artery was much reduced in size by intimal thickening and an organizing thrombus lay in the lumen. There were no changes in the wall of the corresponding central retinal artery, but the lumen was occluded by thrombosis. Both retinal arteries were equally affected in Case 6 of Cooke and his co-workers. The lumen was obliterated by cellular fibrous tissue obviously formed during the organization of a thrombus. The adventitia and media were infiltrated by lymphocytes and plasma cells, and the internal elastic lamina was fragmented and calcified. A few giant cells were engaged in the phagocytosis of calcified fragments.

Greenfield[17] (1951) described the pathologic findings in the eyes of a patient who had become

blind one month before. Histologically, the lesions of giant-cell arteritis were found in the retinal and ciliary arteries of both eyes and in the anterior coronary, internal carotid, middle and anterior cerebral, and anterior choroidal arteries, as well. The retinal and ciliary arteries were the seat of an intense angiitis which involved all three coats and reduced the lumen to a very narrow channel. The thickening of the intima was variable. Lymphocytic infiltration was present in all three coats but most intensely in the adventitia. The retinal arteries, after gaining their position in the center of the optic nerves, showed no destructive lesions of their walls, but there was considerable lymphocytic infiltration round them right up to the surface of the discs. Both optic nerves showed early degeneration of the myelin sheaths. No lesions were found in the central nervous system. Kreibig[18] examined the globe and optic nerve of an eye blinded fifteen days before in the course of an illness interpreted as temporal arteritis. Papilledema had been present and the arteries were slightly narrowed. Histologically, an extensive granulomatous arteritis involved the ophthalmic artery as far as its entrance into the optic nerve, at which point, signs of inflammation became minimal although some side twigs from the central retinal artery showed an infiltration with round cells. The lumen of the stretch of artery outside the nerve was occluded, while within the nerve the lumen was patent. A sector of the optic nerve just posterior to the lamina cribrosa was infarcted and contained fatty macrophages. The possibility that this lesion lay in the territory of a branch of the arterial circle of Zinn was raised, and the author was unable to explain the failure of retinal infarction to occur with total occlusion of the central retinal artery. He used the term "optikomalacia" to indicate the infarctive nature of the lesion.

In Case 12 of Heptinstall et al., a severe visual loss had been present clinically but no histologic evidence of arteritis was found in the ophthalmic or retinal arteries, nor did the optic nerve itself show any gross degeneration (autopsy fourteen months after onset of blindness). In their Case 14, in which bilateral blindness had occurred, giant-cell arteritis without vascular occlusion was present in both ophthalmic arteries and one showed fibrinoid changes in the media; the optic nerves showed little change but both occipital lobes were infarcted and the blindness may have been central in origin. In one case, Meadows[19] found evidence of arteritis and occlusion of the central retinal artery early in its course before it entered the optic nerve.

The patient reported by Lander and Bonnin[20] (1956) was a woman, aged seventy-five, with a typical picture of temporal arteritis who died nineteen days after the onset of bilateral blindness from pulmonary embolism. The characteristic picture of giant-cell arteritis was found in the right internal carotid (minimal), aorta, coronaries, and bilaterally in the superficial temporal, lingual, external carotid (minimal), and ophthalmic arteries. These last showed severe and advanced changes with complete occlusion of the small orbital branches. Wedge-shaped areas of softening, which, like the vascular changes, were more advanced on the left side, were present in both optic nerves; the central vessels of the retina showing only focal adventitial collections of lymphocytes. The site along the optic nerve at which the lesions lay was not stated. Some orbital branches showed unusual large plaques of calcification arranged concentrically in the media and sub-intima.

Whatever the process involving the ocular motor nerves may be, its evanescent effect on nerve conduction is in striking contrast to the permanent damage wrought by involvement of the optic nerves.

C. Additional Remarks Concerning the Two Cases Presented

1. *Diabetes insipidus.*—The occurrence of diabetes insipidus in temporal arteritis has not been previously reported. Although of brief duration in the case presented, the symptoms and signs were unmistakable and pitressin brought prompt relief. There were no other signs of hypothalamic involvement and the patient's mind was lucid at the time of the diabetes. Meticorten had been administered for two days. In Case 2 of Cooke and co-workers, the patient developed excessive thirst and polyuria but the course of these symptoms was not given and there was no additional evidence of hypothalamic involvement. Although a biopsy was not made, the case was undoubtedly one of temporal arteritis. Possibly, confusion and drowsiness (as in Dick's case) have their origin in this region. It has been our experience that victims of temporal arteritis give a very poor chronologic account of their illness but we have thought this was caused partly by cerebral decline associated with aging, and partly by the rather vague nature of the illness.

It is tempting to suggest that in the author's case the impairment of vision—total blindness on the left, and a temporal field defect on the right—resulted from damage in the region of the optic chiasm and that diabetes insipidus was caused by extension of the process to the supraoptic nuclei of the hypothalamus which lie in close proximity. If involvement of the region of the optic chiasm was a regular event in temporal arteritis, a ready explanation would be at hand for the striking occurrence in quick succession, in many cases, of blindness first in one eye and then in the other. Furthermore, it is of interest that each of the three patients with proved temporal arteritis described in this paper *(Cases 1, 2, 5)* was totally blind in one eye while the other eye showed an extensive temporal field defect and any remnant of vision lay in the medial part of the visual field—a pattern compatible with a lesion situated in one optic nerve near the chiasm and involving the adjacent medial fibers of the opposite optic nerve. Such a location for the lesion would explain why, in many cases, at the height of the blindness the retinal arteries not only show no visible evidence of an arteritis, but appear to receive an adequate supply of blood and show no reduction in arterial pressure as determined by ophthalmodynamometry. Pathologic examination of the chiasm in temporal arteritis has apparently not been made. It might be mentioned here that Boyd[21] (1943) referred to Zlotnikob who reported a case of periarteritis nodosa in which the patient had diabetes insipidus associated with peripheral edema, headache, vomiting, hypertension and retinitis.

Damage to the pituitary has been mentioned in three cases studied pathologically but the descriptions were brief. In Jennings'[22] Case 3, the pituitary gland "appeared necrotic," in Gilmour's[23] (1941) Case 3, there were small infarcts in the anterior lobe of the pituitary, and in Ritama's[24] (1951) case, "the hypophysis was disintegrating." In a case of idiopathic arteritis of the aortic branches, Marinesco and Kreindler[25] (1936) thought they were able to demonstrate changes in the pituitary gland to which they attributed the atrophy of the facial tissues.

The presenting picture in our Case 2—dysphagia, trismus, sore mouth, conjunctival and periorbital swelling and mild proptosis—was unusual in our experience and especially confusing because headache was of insignificant proportions. However, the literature contains a few other accounts of similar, although less striking, cases. Occasionally, pain deep within the nasopharynx may be the patient's only complaint in temporal arteritis.

Leiomyosarcoma
of Meckel's Diverticulum

RAMAFIS B. FAHIM, M.D.
JOSEPH HYDE PRATT, M.D.
Rochester, Minnesota

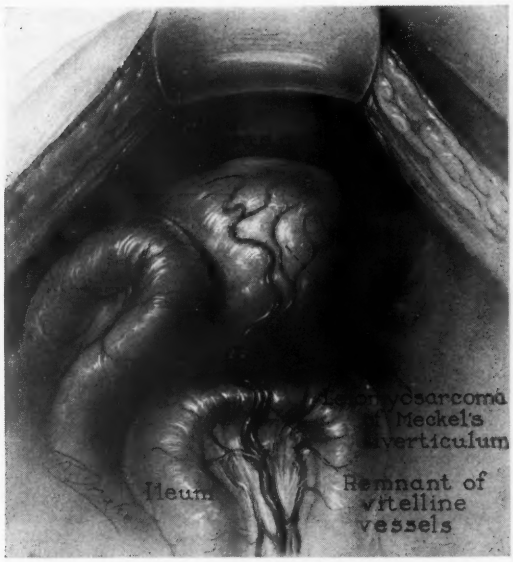

Fig. 3. Diagram to illustrate the origin and the course of enlarged, vitelline vessels.

This report is centered around two cases of leiomyosarcoma of Meckel's diverticulum, which is the commonest malignant tumor involving this congenital malformation. A diagnostic sign of importance is the persistence of the vitelline vessels leading to otherwise unrecognizable diverticula.

From the Section of Surgery, Mayo Clinic and Mayo Foundation.
The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

ABOUT forty neoplasms arising in Meckel's diverticulum have been reported to date. These include leiomyosarcomas, adenocarcinomas, lymphosarcomas, carcinoids and leiomyomas. Of these, leiomyosarcoma, with ten reported cases, appears to be the commonest malignant lesion and we shall therefore limit our discussion to that entity.

Three cases of leiomyosarcoma of Meckel's diverticulum have been reported previously from the Mayo Clinic and we wish to report two additional cases, one of which we encountered ourselves.

Report of Cases

Case 1.—A 47-year-old farmer came to the clinic January 8, 1948, because of three recurrences of massive melena. Six years prior to his admission, he had had an episode of tarry stools for one week for which no treatment was given. Two years later he had had another episode of massive melena which required hospitalization and on one occasion he passed bright red blood from the rectum. A roentgenogram of the stomach

showed evidence of a duodenal ulcer. He was placed on an ulcer regimen which he followed for one year and then abandoned. One month prior to admission to the clinic the patient had a third episode of severe

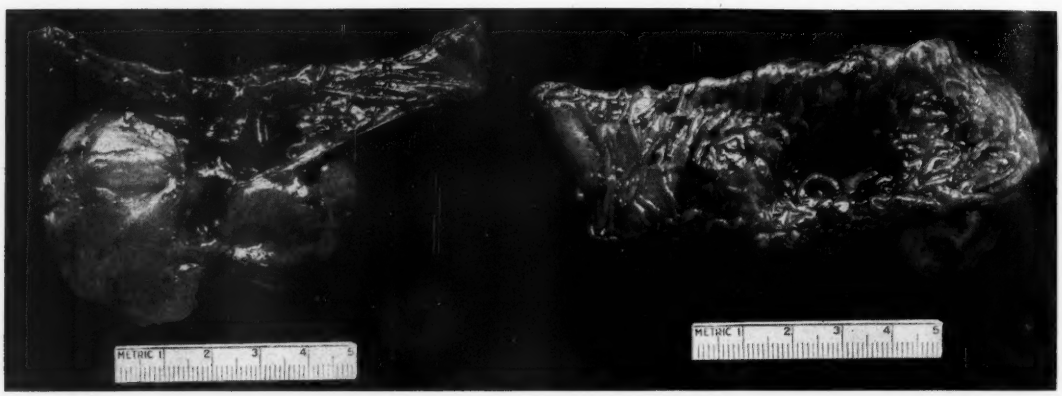

Fig. 1. Section of tumor attached to ileum. Notice the remnant of Meckel's diverticulum within tumor.

Fig. 2. Piece of ileum resected to show the opening of the neck of Meckel's diverticulum leading to the tumor as seen from the inside of the ileum.

melena and again passed bright red blood from the rectum on one occasion. Roentgenograms of the stomach again showed evidence of a duodenal ulcer and it was then that he was referred to the Mayo Clinic for consideration of gastric resection.

The results of physical examination were essentially negative except for some tenderness to the right and below the umbilicus. The duodenal ulcer was confirmed by a roentgenogram made at the clinic. Although the possibility of bleeding Meckel's diverticulum was entertained, a roentgeongram of the small bowel was not made. The hemoglobin determination showed 9.0 gm. per 100 cc. of blood and erythrocytes numbered 4,490,000 per cubic millimeter of blood. The results of other laboratory tests were noncontributory.

On January 20, 1948, exploration was carried out through a right upper midrectus incision. The duodenal cap did not show signs of an active or healed ulcer. A Meckel diverticulum (Figs. 1 and 2) was found, however, and it contained a bosselated tumor which was adherent to the peritoneal lining of the anterior abdominal wall midway between the anterior superior spine and the umbilicus. There was extensive parasitic blood supply from the anterior abdominal wall to the diverticulum. The results of examination of the rest of the small bowel were described as negative and there was no metastasis in the liver or peritoneum. It was assumed, therefore, that the tumor in the Meckel diverticulum was the cause of the bleeding. A short segment of the ileum containing the diverticulum together with the tumor and adherent peritoneum was removed. The intestinal continuity was restored with an end-to-end anastomosis.

The tumor was a grade 2 leiomyosarcoma which measured 7 by 4 cm. and was associated with a Meckel diverticulum. The mucosa of the distal end of the diverticulum was ulcerated, and a tract extended from this portion to a distance of 3.5 cm. in the body of the tumor (Fig. 1). The condition of the patient has been followed for five years since surgical intervention, during which time he has had no further melena; therefore, it is assumed that the melena was due to the ulcerating tumor.

Case 2.—A 61-year-old woman was seen at the clinic on January 27, 1958. Her chief complaint was increasing constipation for three years which forced her to take laxatives and to use enemas regularly. For three months prior to her admission the constipation became more noticeable and she began to feel pain at the tip of the tube when administering an enema to herself.

Her history was noncontributory except for total abdominal hysterectomy which she had undergone sixteen years before admission. At that time both ovaries and tubes were considered normal and were preserved. The small bowel, however, was not examined at the time of this procedure.

General physical examination did not show any abnormality. On palpation of the lower portion of the abdomen, however, a firm, moderately tender, slightly movable mass, approximately 10 cm. in diameter, was felt suprapubically and to the right of the midline. On bimanual examination the mass was found to be in the region of the right adnexa and anterior to the rectum.

Laboratory studies showed the sedimentation rate to be 50 mm. per hour; erythrocytes numbered 4,270,000 and leukocytes 9,500 per cubic millimeter of blood; the hemoglobin measured 11.6 gm. per 100 cc. of blood.

Because of the position and the tenderness of the mass, it was thought most likely to be a twisted, infarcted, or hemorrhagic ovarian cyst and exploration was deemed advisable.

On February 1, 1958, abdominal exploration was carried out through a secondary lower midline incision. A hemorrhagic infarcted mass was found in the pelvis, anterior and to the right of the rectosigmoid. Both

ovaries and tubes were easily identified and were normal in appearance, which excluded the possibility of a twisted or infarcted ovarian cyst. The mass was freed from its bed by blunt dissection and was found to be pendulous and hanging freely from the antimesenteric border of the ileum. A significantly large artery and its companion vein were seen overlying the bowel and extending from the mesenteric vessels to the tumor (Fig. 3*). After dividing these aberrant vessels the tumor was removed together with a cuff of antimesenteric wall of the bowel. The defect, which measured 3 by 5 cm., was closed transversely in the usual fashion. Metastasis to the liver or spread to the peritoneum was not apparent.

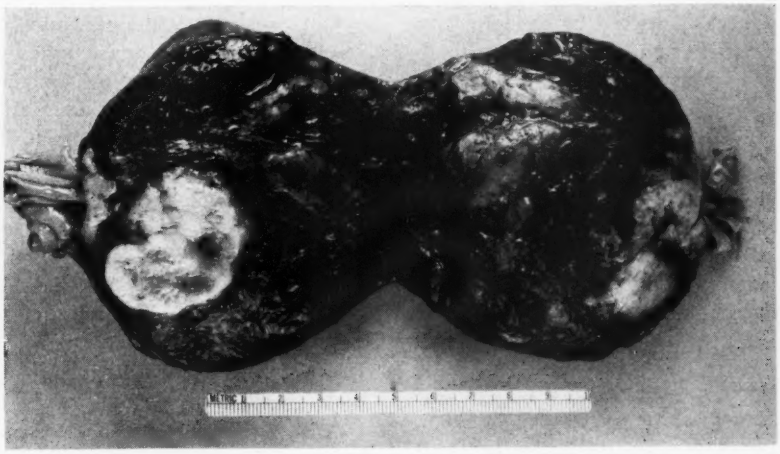

Fig. 4. Cross section of the tumor with attached piece of ileum showing its complete exenteric position and the advanced necrosis.

The tumor measured 9 by 7 by 7 cm. and grossly the greatest part proved to be infarcted (Fig. 4). Microscopic examination showed the tumor to be a grade 1 leiomyosarcoma; no remnants of Meckel's diverticulum were identifiable in the tumor (Fig. 5).

The patient's postoperative course was uneventful and non-morbid; she was dismissed from the hospital on the ninth postoperative day and returned home on the seventeenth postoperative day.

In spite of the fact that no identifiable remnants of a Meckel diverticulum were found within the tumor, it was assumed that the tumor originated in a Meckel diverticulum. Such an assumption was based on the completely exenteric position of the tumor in the terminal portion of the ileum, the pendulous nature of the tumor, the dimpling of intact mucosa at the base of the tumor, and the presence of the afore-mentioned aberrant vessels, the significance of which will be described later.

Comment

Interest was first aroused in leiomyosarcoma of Meckel's diverticulum by Nygaard and Walters[1] who reviewed the literature in 1937 and found reports of three cases of this condition. To these three cases they added two, one of which was their own. In 1939, Skinner and Walters[2] reported another case in which it was possible to demonstrate the diverticulum preoperatively on roentgenograms of the small bowel. The diverticulum, therefore, was thought to be the cause of the melena, but the patient was found to have a necrotic leiomyosarcoma arising in the diverticulum. We have reviewed the literature since that time and have found reports of only four additional cases: (1) the case reported by Moses[3] in 1947 of a patient who had had several intestinal hemorrhages necessitating blood tranfusions, but in whom the tumor finally necrosed and perforated and acute peritonitis developed; (2) the case reported by Thomas[4] of a 32-year-old Nigerian

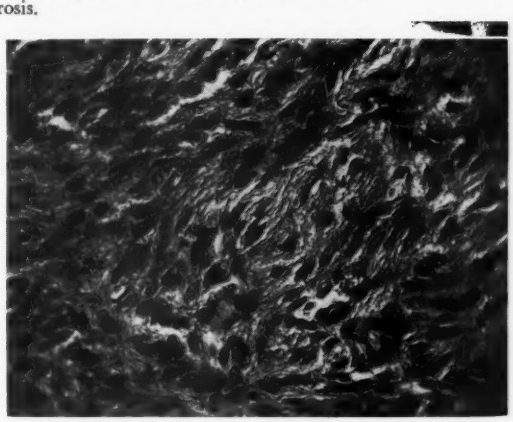

Fig. 5. Microscopic section of the tumor (hematoxylin and eosin; x350). Notice the leiomyomatous nature and its low histologic grade and prominent mitotic figures.

*See Page 1269.

man who had a tumor that measured about 10 cm. in diameter, the presenting feature being recurrent intestinal obstruction; (3) the case described by Barret[5] in 1954 of a 46-year-old man in whom a tumor produced an episode of acute intestinal obstruction; (4) the case described by Sanderup[6] in which skeletal metastasis had developed. The total number of cases of leiomyosarcomas of Meckel's diverticulum reported to date is therefore ten, aside from the two cases reported herein. The other two cases of malignant lesion in Meckel's diverticulum reported from the Mayo Clinic prior to 1937 included the case of a patient with fibrosarcoma reported by Faust and Walters[7] in 1931, and a case of adenocarcinoma arising in heterotopic gastric mucosa described by Kernohan and Gray and reported by Nygaard and Walters[1] in 1937.

In spite of the fact that leiomyosarcomas account for only a fourth of the total number of neoplasms of Meckel's diverticulum described in the literature, they still represent the most common tumor encountered in this location in cases reported in the last two decades. In the cases reported from the clinic, three of five such neoplasms were leiomyosarcomas.

Origin.—It must be made clear that leiomyosarcomas arise from the layers of smooth muscle in the diverticulum and not from the heterotopic gastric or pancreatic mucosa that is frequently encountered in Meckel's diverticulum. Furthermore, adenocarcinoma is more infrequent than sarcoma, there being only ten cases of adenocarcinoma of Meckel's diverticulum[8] reported to date.

Clinical Features.—Among the twelve patients having leiomyosarcoma of Meckel's diverticulum nine were men and three were women. Their ages varied from twenty-two to sixty-six years. The tumor was discovered in the youngest patient during an operation for hernia.

In the cases in which clinical data were available to us, the presenting symptoms were melena, intestinal obstruction, pain, perforation and peritonitis. Melena, which was massive in one of our cases, was also the presenting feature in two cases previously reported: in one patient it was severe enough to necessitate repeated blood transfusion[3] and in the other patient it was moderate and associated with secondary anemia.[2] Intestinal obstruction was the chief complaint in three cases: in one[5] it was acute and in two it was recurrent in nature.[1,4] It is interesting to note that in all cases with intestinal obstruction the tumor was located in the pelvis and obstruction was due to the extrinsic pressure of the tumor.

Pain was a presenting feature in one of our cases and in a previously reported case it was an additional feature,[4] but the amount of pain did not parallel the degree of necrosis of the tumor. Perforation of a necrotic tumor and peritonitis were the presenting features in one case.[3]

A comparison of these symptoms with those produced by leiomyosarcomas of the small bowel shows a striking difference. In seventy-six leiomyomatous tumors of the small bowel, Starr[9] found melena a symptom in fifty cases and abdominal pain a symptom in fifty cases, but intestinal obstruction was not so frequently encountered as when the tumor arose in a Meckel diverticulum.

A mass was felt on examination in one of our cases and in two other cases reported in the literature.[5,8] It is also interesting that all the palpable tumors were located in the pelvis.

A diverticulum was diagnosed by x-ray in one case.[2] Evidence of a diverticulum in association with a tumor on x-ray examination should be interpreted with caution since pseudodiverticula are sometimes seen with necrotic leiomyosarcomas.[9]

Pathologic Features.—The tumors varied in size from 8 to 15 cm. but they were uniformly large, and in all the cases in which a histologic diagnosis was available, the tumors were described as low-grade tumors (Broders' classification).

Neither metastasis to the liver nor direct spread to the peritoneal surfaces was present and these are the only methods of spread of leiomyosarcomas according to Starr.[9] However, in one case encountered by Friedl[10] in 1902, spread to the lymph nodes was reported. Such metastasis, as was shown by Starr,[9] probably represents metastasis to the peritoneal surface with subsequent growth of the metastatic lesion.

The diagnosis of the tumor as one arising in a Meckel diverticulum was based on the presence of a remnant of the diverticulum in seven cases and on the position of the tumor on the wall of the bowel and its location in four cases; in one the criteria are not available. The presence of a remnant of Meckel's diverticulum is the most conclusive evidence of the origin of the tumor. This should not be confused, however, with the epithe-

lized pseudo-diverticula seen in necrotic leiomyosarcomas.[9] An exenteric, antimesenteric tumor of the terminal 2 to 3 feet of the ileum or probably, although not necessarily, originates in Meckel's diverticulum. In a study of seventy-six cases, Starr[9] found fifty leiomyosarcomatous tumors of the small bowel to be completely exenteric and in some cases the mucosa was intact. In the absence of remnants of the diverticulum, as in advanced leiomyosarcomas of Meckel's diverticulum, we wish to emphasize the diagnostic value of enlarged remnants of the vitelline vessels (Fig. 3). These vessels, prominent in one of our patients, have been described previously in two cases reported from this clinic.[1,2] They consist of a sizable artery and its companion vein that arise from the mesentery of the ileum and cross the bowel to supply the tumor. Under normal circumstances they are of smaller size than other vessels but they can be identified easily in the mesentery of a Meckel diverticulum. With the advent of malignant change they may assume extremely large proportions to maintain a blood supply equal to the growth of the tumor. We wish to stress their diagnostic value in the absence of all other criteria.

Treatment

The treatment of choice, as in leiomyosarcomas of the small bowel, should generally be excision of the segment of bowel containing the tumor and end-to-end anastomosis.[9] From the surgical standpoint there are two important factors. First, the benign tumors are small. The large tumors, 7 cm. or more in diameter, were uniformly malignant according to Starr,[9] and even when the microscopic picture of malignancy is not clear, the tumors undoubtedly will act like true malignant neoplasms by metastasizing and causing the death of the patient. Therefore, since these leiomyosarcomas are usually radioresistant, every effort should be made to extirpate them surgically. At the same time any identifiable metastatic lesions that are accessible should be removed also.

Second, leiomyosarcomas of the small bowel and also those of Meckel's diverticulum spread by peritoneal seeding or spread via the blood to the liver. They rarely, if ever, spread via the lymphatics. If complete removal of the tumor can be accomplished by removing a segment of ileum or a large portion of the wall of the bowel, it is not necessary to take a deep wedge of the mesentery of the small bowel and run the risk of possible interference with the blood supply to the remaining portion of the intestine.

Prognosis

In leiomyosarcomas of the small bowel, Starr[9] found higher survival rates in cases in which a segment of the bowel was resected with the tumor. He also reported the survival rate to be more than 50 per cent in cases of grade 1 lesions but it was poor in cases of high-grade sarcomas. These figures should be applicable to lesions of Meckel's diverticulum also, although data on all of these twelve cases are not available. One of our patients survived five years only to die subsequently of a heart attack.

Summary

Two cases of leiomyosarcoma of Meckel's diverticulum encountered at the Mayo Clinic have been added to the ten cases already reported in the literature. The pathologic, clinical and anatomic features of this intriguing entity were analyzed.

The persistent vitelline vessels are of great diagnostic importance when an identifiable remnant of the Meckel diverticulum is not present. Removal of local growth and accessible metastatic lesions is extremely important. Lymphatic spread is rare and therefore resection of a deep wedge of the mesentery of the small bowel is unnecessary.

Hemolytic Anemia with Cold Hemagglutination and Atypical Pneumonia

ROBERT B. BREITENBUCHER, M.D.
Minneapolis, Minnesota

COLD hemagglutination usually refers to the clumping of red cells in a mixture of a serum or plasma at refrigerator temperature. If the cold hemagglutinin titre is high enough, however, the clumping may be observed even at room temperature. The agglutination is completely and rapidly reversible at body temperature or 37° C. Cold hemagglutinins have been described in a variety of unrelated conditions such as cirrhosis of the liver, pregnancy, leukemias, yaws, atypical pneumonia and rarely in apparently normal individuals. The most common association seems to be that of cold hemagglutinins in atypical pneumonia. This association was described by Peterson, Hamm and Finland[1] in 1943.

Although cold hemagglutinins are rather commonly found in cases of atypical pneumonia, the association of a hemolytic anemia with cold hemagglutination, to any marked degree at least, is rather unusual. The hemolytic anemia in these cases is acute but recovery can be expected approximately paralleling recovery from the pneumonia.

Report of Case

This case is that of a 29-year-old woman who was admitted to St. Mary's Hospital under Dr. W. L. Herbert on February 5, 1958. About three weeks before admission, she had a chest cold with a persistent cough productive of small amounts of sputum. Ten days before admission, she consulted Dr. W. L. Herbert who took a chest x-ray and made a diagnosis of pneumonia. Hospitalization was advised but refused by the patient. She was then treated with Achromycin and advised to remain in bed at home. She did not comply with this advice but continued to do her daily housework. She became afebrile but coughing of yellowish sputum persisted and she became very weak. When she again consulted Dr. Herbert she was extremely pale and this time, he insisted upon hospitalization.

Family history, past history and system review were essentially noncontributory. Physical examination revealed a well developed, very pale white woman. Blood pressure was 120/60 and pulse 120. There was a slight icteric tinge to the sclerae. There was no significant lymphadenopathy. There were a large number of inspiratory coarse moist rales in the left lung base and classical signs of consolidation including bronchial breathing and dullness over the right lower lobe. The heart was normal in size. There was a grade I short apical systolic murmur. Spleen and liver were not palpable. The remainder of the examination was normal.

Laboratory.—Routine urinalysis revealed a specific gravity of 1.026, negative albumin and sugar and negative microscopic. Hemoglobin was 6.3 grams. White count was 14,100 with 77 per cent neutrophiles, 19 per cent lymphocytes, 3 per cent monocytes and 1 per cent eosinophiles. On blood smear the red cells showed a marked increase in polychromasia with occasional normoblasts. There was marked clumping of the red cells. Platelets were normal and leukocytes were normal. Her total serum protein was 7.2 grams per cent with 4.7 grams albumin and 2.5 grams globulin. Reticulocytes were very numerous but accurate counting could not be done because of the clumping of the red cells. The cold agglutinin titre was greater than 1:8, 192, and macro cold agglutinins were easily demonstrable. X-ray of the chest revealed an extensive mottled confluent pneumonitis involving the lower third of the right lung.

Course in the hospital.—The patient was treated with Prednisolone 15 mgm. and Achromycin V 500 mgm. every six hours. Room temperature was raised to between 80° and 88° and kept at this temperature. On this regimen, gradual improvement was noted until by February 22 the hemoglobin was 11.2 grams with a hematocrit of 35 per cent. Cold agglutinins had reduced by this time to 1:512 and the pneumonia had cleared. Prednisolone was tapered off until by the time of discharge she was receiving none.

Comment

This case seems to be typical of others that have been reported in the literature.[2] This patient, however, did not have Raynaud's phenomenon or any other obliterative vascular phenomena which have been commonly observed in other cases. These phenomena are apparently due to intravascular clumping of the red cells with plugging of the capillaries and smaller arterioles.[3,4] At times this may actually lead to gangrene of the extremities.[5] Splenomegally was absent in this case as seems to be the rule in previously recorded cases associated with atypical pneumonia.

The mechanism of the hemolytic process has not been clearly defined. The level of hemagglutinin titre does not seem to be the only factor in the development of hemolysis.[6] It has been demonstrated that cold agglutinated red cells are mechanically fragile.[7] Erythrophagocytosis of the damaged cells may account for some hemolysis. This is probably not the only explanation for the red cell destruction that occurs. Various hemolysins have also been demonstrated in these patients.[2]

The management of these cases includes keeping the patient warm, treating the pneumonia and giving steroid therapy. The necessity of keeping the patient warm cannot be over emphasized. The *in vivo* hemolysis induced by chilling a patient's arm has been demonstrated experimentally.[8] Gangrene developing in an arm close to a cold outside wall in the hospital has been seen.[9] Room temperature should be kept between 80° and 85°. The patient should be instructed to keep the extremities under the covers. Cold oxygen tents should not be used. Sponging of the patient and exposure during baths should be avoided and even cold drinks should be forbidden.

Transfusion at times may be necessary but should be performed with great caution. First of all, it is very difficult to cross-match these patients due to the cold hemagglutination interfering with the usual method of cross-matching. Cross-matching must be done with warm slides to be at all successful. Furthermore, the administration of cold bank-blood may be disastrous. If a transfusion is done, the blood should be warmed to body temperature before it is administered and should be kept warm during administration.

Treatment of the pneumonia is accomplished according to the usual means. The administration of steroids is perhaps a little empirical but they seem to have been of some benefit in previously reported cases[2]. Their true relative value, however, is a little difficult to assess.

The Physician and the Minnesota Teen-age Code

ALBERT J. SCHROEDER, M.D.
Minneapolis, Minnesota

Dr. Schroeder is Chairman, Committee on Juvenile Delinquency, State of Minnesota Chapter, American Academy of Pediatrics.

THE physician is in a unique position to assume leadership and lend support to the community efforts promoting child health and welfare. His close and early contact with both parent and child often allows him to be aware of contributing factors leading to possible deviant behavior in the child, and youth, before he comes in conflict with the laws of his society.

Desiring to emphasize the important potential of preventive action in the area of delinquency of youth, the Minnesota State Chapter of the American Academy of Pediatrics has been interested for some time in a challenging program existing in our state in the form of a teen-age social code.

We are fortunate in Minnesota in having effective existing organizations which have been working on the juvenile problem for some time and with results. Among these groups, the Governors Advisory Council on Children and Youth has formulated the "Minnesota Teen-Age Code." This code has achieved enthusiastic support in our state and attracted national attention. Correspondence regarding the code and requests for copies have been received from nearly every state. Actually, several states are initiating similar programs after observing the strong support our Minnesota Code program has received from parents and youth.

The Minnesota Pediatric members felt this excellent program should be emphasized to all physicians of our state as deserving of their interest, and, should they be called upon to aid it, their cooperation. Accordingly the program of the "Minnesota Teen-Age Code" was presented to the Council of the Minnesota State Medical Association and unanimously approved at the October, 1958 meeting. The hope is that this action will enlarge physician interest and participation in the program at the local community level.

What is the "Minnesota Teen-Age Code"?[1]

The Minnesota Teen-Age Code is a set of guiding principles developed to help achieve cooperation among parents and students for a safe and acceptable program of social activities for young people. It is based on parent and student surveys here and elsewhere and is issued by the Governor's Youth Council and the Governor's Advisory Council on Children and Youth.

How was a Code Developed?

The original draft was prepared by youth themselves at the Governor's Conference held in May, 1956. It was then forwarded to youth throughout the entire state who were given the opportunity to discuss it and revise the original. This second draft was then studied by the Governor's Advisory Council and a final draft prepared. It is estimated that over 600 youth and 300 adults have participated in the preparation of the Code.

Why a Code?

As young people mature, they desire more freedom. They usually welcome direction but they resent arbitrary orders. Because of group pressures young people are often placed in difficult situations. They want and need the understanding support of their parents and they frequently admit to a need for some guide of behavior.

Many parents feel a need for support in combating the argument from their teen-agers that "Everybody does it." Also, teen-agers need protection from adults who impose unreasonable standards. By setting up desirable and acceptable standards of behavior in these age groups, parents and young people can help to avoid later problems.

What are the Contents of the Code?

The Code is intended to be a basis for determining acceptable conduct regarding: (1) parties; (2) use of the car; (3) suitable hours; (4) appropriate dress; (5) the problems of party crashing; (6) proper respect for rights and property of

others; (7) smoking by teen-agers; (8) drinking of alcohol.

How May the Code be Started?

The code to be understood, well received and respected must be the local product of parents, teachers, and youth. Then it most successfully reflects the needs, standards and attitudes of the particular school or community involved. Parent-Teacher Associations serve as ideal sponsoring organizations since they can conviently reach parents, teachers, and youth. To accompany the code, realistic curfew regulations are necessary and these are the result of the joint action by citizens, and local enforcement agencies.

Does the Code Work?

This is still impossible to answer in a final way. Recently the principal of a local school reported: "Parents don't demand 100 per cent obedience to the code at all times, nor do students live up to it 100 per cent. Nevertheless, the over-all effect has been good."

It is a long term project but by the spontaneous enthusiasm it has generated in youth, parents and authorities, it appears to be going in the right direction. And it is uniting the effort of the community forces like nothing else tried to date in our state! Our state is busy laying the groundwork to make an all-out effort to put the code into all of our 1300 communities. It is now in operation in 113 cities including our two largest cities. There are at present some 271 schools in Minnesota that have taken some action in reference to the code.

Why Should the Physician be Interested?

Along with other citizens the physician participates and lends leadership to programs for community improvement. It is a natural role for the physician to be associated with a program that attempts to develop in a community a guide for the range of normal behavior in children and youth.

One of the physician's assets most needed and constantly used by parents is his knowledge of the normal range of behavior and activity, whether it is about feeding, bowing of the legs, or the variations of acceptable conduct of teen-agers. In this area he is on very familiar ground. The physician's support of a community group, whether it be school, church, PTA, or community council in the establishment of a Teen-Age code, will lend prestige, professional standing and impetus to the program.

A booklet* entitled "Minnesota Teen-Age Code" contains a suggested code for the Junior High School level (Grades 7, 8, 9), and the Senior High School level (Grades 10, 11, 12). Included is a model curfew ordinance.

Printed below is that protion of the Minnesota Teen-Age Code relating to the Senior High School.[1]

MINNESOTA TEEN-AGE CODE

Senior High School

Grades 10, 11, and 12

Basic Rule

Parents should know where their sons and daughters are while away from home, what they are doing, and with whom they are spending their time. Parents should also know what time their young people return home.

Parent-Youth Planning

(A) An allowance should be planned together, based on a discussion of financial ability, needs, and the management of money.

(B) Family plans should be organized so that: (1) necessary transportation for all members of the family can be provided; and, (2) individual members can be reached in case of emergency or change of plans.

Home Entertaining

The home should be the center of young people's social activity. To accomplish this, the co-operation and support of parents is needed. Young people should be encouraged to bring friends into the home and to accept the invitations to visit the homes of friends. Parents should welcome the opportunity to meet their sons' or daughters' companions and friends.

(A) It is important that invitations be clear as to type of function (for appropriate dress), the time of beginning, and ending of a party. It is the responsibility of the guests to leave at the designated time.

(B) It is important that a parent or responsible adult be at home and on call at all times when young people entertain but should provide an agreeable measure of privacy.

(C) Young people and their parents feel more comfortable if some plans for entertainment have been made in advance. Boredom and confusion lead to undesirable

*Copies of the "Minnesota Teen-Age Code" and the "Minnesota Teen-Age Code Handbook" may be secured by writing to: Governor's Advisory Council on Children and Youth, 129 State Office Building, Saint Paul 1, Minnesota.

results. Well laid plans for a party are disregarded only by a rude guest. A considerate guest will follow the plans of the host.

(D) Party crashing is an inexcusable custom and presents a problem for the host and other guests. Crashers should not be admitted.

(E) "Lights out" has no place in a well-ordered party.

General Dating

(A) The home should be offered and encouraged as a possible place for dating. Parents should co-operate by providing an agreeable measure of privacy. Public entertainment puts a strain on teen-agers' allowances.

(B) Dressing according to the occasion makes a person feel more comfortable.

(C) Young people and their parents should agree in advance on a definite time for return from a date. A boy should be given an opportunity to meet the parents of the girl and to discuss expected time of arrival at home.

Hours

In deciding on a satisfactory hour for a young person's expected arrival at home from a social engagement, two factors have to be considered: *(1) What time will the affair be over? (2) What is a reasonable amount of time to allow for arrival home following the affair?*

1. *What time will the affair be over?* The following is a suggested guide for:

(a) Non-school nights:

	GRADES		
	10th	11th	12th
Formals	11:00	12:00	12:00
	12:00	1:00	1:00
Informals	11:00	11:00	11:00
	11:30	12:00	12:00
Home parties	11:30	12:00	12:00
General dating	11:30	12:00	12:00

(b) School nights:

10:00 except for special events, such as school, church or other recognized activities.

2. *What is a reasonable amount of time to allow for arrival at home?* (If transportation is provided by parents, this is no problem.)

(a) An invitation issued for refreshments following a dance or other late social function should include a definite time for beginning and ending. One hour would seem adequate for an occasion of this type but is subject to regional conditions.

(b) Young people should come directly home from a function unless other plans have been approved by parents. *If a young person is delayed for any reason, he should telephone home.*

(c) Parents should know when young people arrive home.

Driving

(A) Parental consent for the driving privilege should be based on: (1) Possession of a driver's license; (2) young people's proof of ability to control themselves and the car; (3) a healthy attitude regarding the rights and welfare of others.

(B) Because it affects the lives and property of others, teen-agers should be allowed to drive a motor vehicle *only* with a license (or permit) issued by the Drivers' License Division of the State of Minnesota. A licensed driver must accompany the teen-agers driving with a permit. State law prohibits anyone from allowing another to drive a motor vehicle without a driver's license.

(C) *Trained instruction is urged.* Careful driving, as well as good driving attitudes, can save lives and secure the economic welfare of an entire family.

(D) It is the duty of parents and youth to make certain that any car driven by young people is in safe operating condition.

(E) Young drivers should be expected to assume their portion of responsibility for the maintenance and appearance of the shared car.

(F) Parents should be firm in their decision to take away the car privilege when it is abused. On the other hand, they should be generous in their praise of proper driving attitudes and careful handling of the car.

(G) Young people should understand that overcrowding of a car is dangerous.

(H) Riders have a share in the responsibility for safe driving. Dares and jeers from riders have been responsible for more than one death.

(I) Young people should understand that it is wise to refuse to ride with a reckless driver. Call your parents, or call a cab.

Drinking

Drinking among high school students presents a serious problem in which parents and youth must consider their responsibilities. Young people confirm that a number of parents serve alcoholic beverages (beer, wine and whiskey) to young guests in their homes. It is well known that alcoholic beverages are brought to parties by guests, and are served by the guests themselves.

(A) No one has the moral or legal right to serve any alcoholic beverages to other people's children. The adult who does so may be charged criminally and is directly responsible for any of the serious consequences which may result.

(B) Minnesota State Law prohibits sale of liquor or 3.2 beer to minors (under 21 years of age) and forbids serving it to them and consumption by them.

(C) Parents should impound any alcoholic beverage which is brought to a party and notify the parents of the offender. No alcoholic beverages should be accessible to young guests.

(D) Young people should understand that it is not a disgrace to decline an alcoholic drink.

(E) Young people should understand that it is foolhardy to ride with a driver who is under the influence of alcohol, and should instead seek safer means of transportation.

Smoking

(A) Minnesota State Law prohibits sale of cigarettes and tobacco to persons under 18 years of age and prohibits such persons from smoking except in their home with their parents' consent.

HORMONE WITHDRAWAL BLEEDING AS A PREGNANCY TEST

The physician frequently desires to diagnose the presence or absence of a gestation in a patient whose menses are only a few days overdue. The conventional biologic pregnancy tests usually are not sufficiently sensitive to detect a gestation of less than one month's duration since they depend upon chorionic gonadotropic hormone, which does not rise to a sufficiently high level before that time. The principle of hormone withdrawal bleeding can be used as a pregnancy test and is especially useful in the diagnosis of early pregnancy. Three methods will be discussed briefly.

One series of patients received a daily injection for three days of a combination of 2.5 mgm. of estradiol benzoate and 12.5 mgm. progesterone, commercially known as Prometron (Schering). The non-pregnant patients had menses between two and fifteen days after the last injection. Most of this group menstruated after four or five days. None of the pregnant patients bled except for one who spotted slightly.

A second series of patients received 100 mgm. progesterone in one dose intramuscularly. The non-pregnant patients menstruated between two and fourteen days after the last injection, with most requiring five to six days. The pregnant patients did not bleed.

A third series received orally four tablets daily for three days, each tablet containing 50 mgm. of anhydrohydroxyprogesterone and .03 mgm. ethinyl estradiol, commercially known as Pro-Duosterone (Roussell). The non-pregnant patients menstruated from two to fourteen days later. Most started bleeding two to four days after concluding the pills.

If progesterone with or without estrogen is administered to a patient whose menses are a few days overdue, the pregnant patients should not bleed, but the non-pregnant patients should have a menses due to hormone withdrawal bleeding. In the great majority of all of the above tests the flow induced by the hormone withdrawal was similar to normal menses. Occasionally, the patient stated that the flow was slightly scanty or slightly prolonged.

Hormone withdrawal bleeding approaches 100 per cent accuracy as a pregnancy test provided it is used in women whose menses are not over a couple of weeks overdue and whose previous menses have been fairly regular. When the test was applied to women who had not menstruated for more than three months, most of the non-pregnant women menstruated, but the number of non-pregnant women who did not menstruate was increased. It is in early pregnancy where the test is most needed and most accurate. The interval between medication and flow apparently depends upon many factors including when given in relationship to ovulation and the previous priming of the endometrium by estrogen. Hypothyroidism and adrenogenital syndrome could influence the picture.

Recently, it has been found that pseudohermaphroditism may be present in female infants born of mothers who received progesterone, especially the androgenic steroids, during pregnancy. None of the infants born after the described hormone tests had pseudohermaphroditism.

It may be concluded that the principle of hormone withdrawal bleeding may be used as a safe and accurate pregnancy test.

HAROLD A. SCHWARTZ, M.D.

POLYBECHIA

Two contrasting aspects of the problem of coughing are thought-provoking: (1) its ubiquitous high prevalence; (2) the neglect of its treatment. Cough is common in children, adults and in the aged. It is noted perennially, with peak of frequency in winter. Why is it neglected? Possibly, because the individual and persons about him become habituated to it. Secondly, because its potential hazards are not appreciated. Thirdly, because of easy accessibility of over-the-counter cough remedies, none of which cures the disease that is causing the cough. Our responsibility in correcting this anomalous situation lies in effective prevention and etiologic treatment. Preventive measures cover a vast field of endeavor from atmospheric sanitation to personal prophylaxis. Accomplishments in both of these directions are far

behind the ideal. Adequate treatment has two prerequisites. First, the public should be made aware of the importance of this issue so that remedial intervention could be done early. Secondly, the medical profession should offer better diagnostic and more effective therapeutic means.

Harmful effect of cough may be immediate or cumulative. Immediate damage is possible in the form of pulmonary hemorrhage, hematemesis, spontaneous pneumothorax, interstitial emphysema, pneumomediastinum, tussive syncope, strain on the right ventricle, pain in the chest, dyspnea, exhaustion, vomiting, loss of appetite, headache, insomnia, fracture of ribs, interference with healing of pulmonary disease, spread of infection within the lung, bronchospasm, asthmatic attack. Cumulative damage may be found in the form of pseudohypertrophic emphysema (hypertrophic, obstructive emphysema), heart strain and hernia, including hiatus hernia.

In reference to cough as a diagnostic clue, it is expedient to focus inquiry on certain categories and suggestive leads. Cough is observed in febrile affections such as common cold, bronchitis, lung abscess and in specific diseases such as whooping cough, fungus infections, tuberculosis, pneumonia of viral or bacterial origin. Lung involvement occurs in 20 to 60 per cent of tularemia and in 30 per cent with brucellosis; in rheumatic fever, incidence of specific pneumonia varies from 1 to 10 per cent. Cough may be noted during the course of exanthematous communicable diseases of childhood. As a matter of fact, lesions of measles in the bronchi and bronchioles are well established by the time skin rash appears. Other diseases with fever and cough include diphtheria, amebiasis, melioidosis and some instances of toxoplasmosis, syphilis, anthrax, glanders and some of the parasitic infestations. Patients with longstanding cough should be scrutinized for chronic diseases of the upper respiratory tract, chronic bronchitis, pneumonitis, lung abscess, tuberculosis, fungus infection, bronchiectasis, bronchial asthma, pulmonary fibrosis and sarcoidosis, emphysema, heart disease with mitral stenosis or left ventricular failure, cystic disease of the lung, benign and malignant tumors of the lung, mediastinum and other thoracic structures and organs and pulmonary alveolar proteinosis. Sudden, spasmodic cough, without fever or with slight elevation of temperature may result from aspiration of foreign body or food, from asthmatic bronchitis, bronchial asthma, rupture of an abscess or cyst into a bronchus, pulmonary infarction, pulmonary edema, pulmonary hemorrhage, bronchitis due to inhalation of noxious fumes and gases, migrating broncholiths, laryngeal edema, bronchopleural perforation of empyema.

Concerning cough in infants and children, reference has been made to infections of the upper and lower air passages and to bronchial asthma. It is well to keep in mind the possibility of mucoviscidosis (fibrocystic disease of the pancreas) an increasingly large number of which are diagnosed in daily practice. Aspiration of foreign bodies provokes much coughing and gagging. Even so, in some instances the episode is forgotten until symptoms of lung abscess bring the patient to the physician. Debilitated infants and those with anomalies causing faulty deglutition may be found to have lipoid pneumonia. Foreign body in the esophagus may incite cough. Esophagotracheal, esophagobronchial fistulas, esophageal atresia are associated with cough. Other possible causes of cough are tumors of the larynx and trachea, congenital absence of tracheal cartilages, compression of the trachea by the thymus, enlarged lymph nodes, enlargement of the heart, anomalous blood vessels, mediastinal tumors or bronchial cysts. Insidious cough with severe anemia may signalize hemosiderosis. Hand-Schueller-Christian disease shows its highest incidence during the first decade of life. Cough may make its appearance at birth in some cases of intralobar sequestration.

Of the population of the United States, 10 per cent are over the age of sixty-five. This group has an increased susceptibility relative to cardiopulmonary diseases. Therefore close attention should be paid to the origin of cough, with reference to the high incidence of chronic bronchitis and pneumonitis, fibrosis, bronchial asthma, pseudohypertrophic emphysema, bronchiectasis, bronchogenic carcinoma, arteriosclerosis and heart failure.

When past history and family history are suggestive of an allergic background, one should remember that cough may precede bronchial asthma by years. In some of these individuals with allergy cough may be attributable to allergic bronchitis, cold allergy, Loeffler's syndrome or lung lesions associated with erythema nodosum.

Cough occurring when the person changes position from erect to horizontal, stoops down or bends over may signify spilling of exudate or for-

eign material from smaller into larger bronchi. Diagnostic studies should be directed toward bronchiectasis, infected lung cyst, lung abscess, bronchopleural fistula, cardiospasm and diverticulum of the esophagus.

Cough that is more pronounced at night should bring to mind the following possible provocative causes: heart failure, tumors of the lung and mediastinum, enlarged mediastinal lymph nodes, allergic bronchitis.

It can be seen that cough is an important signal calling for accurate diagnosis as well as for proper treatment of the symptom and its causative disease.

ANDREW L. BANYAI, M.D.

MEDICINE'S GREATEST PROBLEM

John Bunyan, in "Pilgrim's Progress," described the man with the muck rake who was so engrossed with the muck about his feet that he did not have time to lift his eyes to see the vast and ever-changing beauties of the skies.

Considering medicine as not only the body of people who practice this profession, but accepting the theme of medicine as a broader concept of the philosophy and practice of the art and science of medical care, many facets of its problems at once present themselves. It is relatively easy to simplify the question according to one's major interests and to the locality in which one works. The problem of communicable diseases including tuberculosis throughout the world is huge. The nutritional aspects of cardiovascular disease, the apparent increase in neoplastic disease, the physiological and social aspects of aging, the growing awareness of the psychological factors in disease, are only some of the questions which might be regarded as great medical problems. Consideration of such subjects as these is interesting and could lead to weighty discussions of statistics, of global incidences, of scientific attitudes, and of therapeutic successes and failures. But would not such a discussion be comparable to the attitude of the man with the muck rake, concentrating on one facet only of the entire field of medicine?

Medicine implies consideration of those who are engaged in its practice and the training of medical students must be included in the discussion of our leading question. During the past five decades, vast strides have been made in the knowledge of the human body both in health and in disease. The scientific basis of medicine has become more complex with increasing knowledge of physiological and pathological processes. The advent of cytochemistry, of new methods of study with radio-isotopes, of new methods of culture of cells, bacteria and viruses, and many other technical developments have extended the fields of study necessary as a background to the clinical understanding of disease. In the clinical field, diagnostic advances have led to a demand for highly trained technicians and expensive equipment to carry out analyses and studies of various fractions of or excretions from patients, and the well-trained clinician is expected to be able to interpret the significance of minor variations from a normal pattern. In the realm of therapeutics, new and effective drugs are being developed at a phenomenal rate, and their name and effect is legion. As these new advances must be imparted to students, the medical educator is faced with the problem of training medical students in such a manner and within a reasonable space of time to the degree that they have all the basic knowledge necessary to utilize these advances in the best interests of those who eventually are entrusted to their care. All medical educators are conscious of the demands being made on the time and mental capacity of students and the problem of the best means of utilizing the relatively short time for formal training in such a vast and varied field. The maintenance of a balance between time and content in medical training is one problem which yet remains to be solved.

For the trained and practicing members of the medical profession, some degree of specialization has become a *sine qua non*. This development appears to have become inevitable, as the total sum of knowledge has become so great that it is no longer possible for one man to have complete knowledge of even one subject in medicine, let alone the entire field. Consequent on the increasing need for laboratory and technical services in diagnosis and in treatment, it is difficult for the medical man to maintain direct and personal contact with his patient except for brief periods. The close personal relationships which formerly existed and are tritely called the "doctor-patient relationship" are in danger of becoming a tenuous myth. Carried to its absurdity, the present trend in specialization could lead to the appearance of the "branch bundle block" specialist who might never see a patient but would conduct a remunerative practice in diagnosis and treatment from his expensively appointed office on the basis of electro-

cardiograms taken by a technician. There is an acute danger of complete loss of perspective on the part of the profession as the result of increasing specialization and this problem requires careful thought and some action if Medicine is to avoid fragmentation.

Members of the profession who are most concerned with disease control on a broad community basis are acutely aware of the many problems of a medico-social character which are arising. In many countries in the world, the control of communicable diseases and improvements in maternal and child care, with the subsequent fall in neonatal and adult death rates, has led to a rapid and perhaps alarming population increase in these countries. It is natural that the question is repeatedly asked as to whether these results of improved medical care are beneficient to the community as a whole. Where the total available resources of a country in food, housing, and material comforts are limited, is this increase in population, which is a direct result of medicine, going to lead to overwhelming medical and social-economic problems in the future? It may be that want, poverty, aging and mental ill-health will increase in the future. This major question faces the medical and Governmental administrators and future community planning must take cognizance of this fact. The closest study of this question involves not only the economists, sociologists and agronomists, but also the medical profession. Medicine must realize the social and economic impacts of medical science and accept its share of the responsibilities which are entailed.

I have referred to only a few of the many great problems which are requiring solution. If we accept the concept that the aim of medicine is to promote the well being, happiness and contentment of mankind rather than the negative view that medicine is concerned only with the treatment of overt disease, then it is necessary that the practitioners of medicine reappraise their attitudes and recognize and face the many problems which are now being presented. To me, therefore, medicine's greatest problem is one of re-orientation to the vast complexities which have arisen from progress in the scientific fields, and the changes which have taken place in the relationships between medicine and the people. Medicine must cease its absorption in minutiae of detail and further examine its relationships with humanity. The danger of an increasing isolation from the community as medicine retreats within its laboratories and its gadgetry must be realized. The impacts of advances in medical science have had community-wide effects and medicine must play its part in solving the resulting problems which the community faces.

Might I therefore propose that medicine's greatest problem is to recover and to develop its sense of proportion in the light of increasing scientific knowledge and extreme specialization, and in so doing to provide benevolent leadership in the field of human relationships and understanding. Medicine may in this manner really contribute to the health of mankind.

ANTIHYPERTENSIVE AGENTS
III. Their Disadvantages

To the physician who has had experience in the use of hypotensive drugs, the disadvantages of present medical therapy are obvious.

Expense.—The medical treatment of hypertension is expensive. When large doses of medicaments are required, it is not unusual that the cost of drugs alone may be in excess of a dollar per day. This does not include professional fees for constant supervision of their administration. It is no wonder that our neurosurgical colleagues remind us that extensive thoracolumbar sympathectomy is less expensive than medical therapy.

Tedium.—The medical treatment of hypertension can be tedious and time-consuming for both patient and physician. Success frequently requires perseverance and intelligent cooperation on the part of the patient, together with patience, sympathetic understanding and meticulous attention to detail on the part of the physician. Only if the physician himself is convinced of the value, importance and efficacy of medical treatment will he be able to engender the necessary enthusiasm for such therapy in his patients.

Side Effects.—The greatest disadvantage of present hypotensive therapy is the high incidence of unpleasant, annoying and sometimes dangerous side effects that it induces. Fortunate and rare is the hypertensive patient whose blood pressure can be adequately controlled with drugs without the production of pharmacologic side effects. Too

often, unfortunately, an otherwise successful therapeutic regimen must be abandoned or modified to the detriment of its effectiveness because of intolerable or dangerous side effects. Skillful manipulation of drugs, coupled with kindly persuasion, will reduce the incidence of such failures but will not eliminate them.

Drug Failure.—With the hypotensive drugs presently available, it is frequently impossible to obtain a smooth and even decrease in blood pressure. One usually must settle for reduction of the average blood pressure and recognize that occasional hypertensive intervals are to be expected. Such erratic control of blood pressure has not been incompatible with good therapeutic results. In only exceptional cases is hypertension totally resistant to drug therapy. When failure occurs, it usually results from the patient's inability to tolerate effective doses because of side effects.

Patient Failure.—Successful medical treatment of hypertension depends ultimately on the patient's taking medicine regularly and in adequate doses. In this regard, patients tend to grow careless about regular visits to the physician, to omit or alter doses or to stop medication entirely, even when side effects are not extremely troublesome. Patients resist taking medicine when they feel well, they forget about it, they grow weary of a regimented program, especially if they sense disinterest on the part of the physician, or they get bad advice from well-meaning friends and neighbors. The incidence of patient failure is reduced if the patient is intelligent and has been thoroughly indoctrinated in the aims, objectives and importance of medical treatment. The recording of blood pressure at home is a strong deterrent to negligence in adhering to a therapeutic program. Again, the neurosurgeons have cause to criticize medical treatment, for patient failure is not a factor in the success or failure of surgical sympathectomy. If surgical treatment is successful, it reduces blood pressure whether the patient is cooperative or not; the benefit so obtained does not depend on fidelity to a strict regimen nor can it be revoked by capriciousness.

Palliation.—The forebearing patient and his conscientious physician derive no solace from the fact that present therapy for hypertension is palliative, not curative, and, therefore, all the associated tribulations and difficulties must be endured indefinitely if hypertension is to be controlled.

Patients should not be denied the benefits of hypotensive therapy simply because it is inconvenient and cumbersome. Experience in the use of antihypertensive agents makes the obstacles appear less formidable. Dissatisfaction with present therapy should, however, stimulate the search for more nearly ideal hypotensive agents. This quest eventually will unravel the mysteries of the cause of essential hypertension and lead ultimately to the discovery of its cure.

President's Letter

FORAND BILL SHELVED?

Thanks to the American Medical Association, the American Hospital Association, the American Dental Association, the Health Insurance Association of America and many Doctors of Medicine as individuals, the Forand Bill (H.R. 4700) has been shelved until next year. The bill is still before the House Ways and Means Committee but Representative Aime J. Forand stated that "I don't think we will be able to get this legislation to the floor before adjournment." However, he was "hopeful of action early next year." Therefore, we must still be on the alert.

It is encouraging to note that Arthur S. Flemming, Secretary of Health, Education and Welfare, told the Committee that "passage of the Forand Bill would mark the beginning of the end of voluntary insurance for the aged in the health field." He also stated that "instead of abandoning voluntary hospital insurance for the aged in favor of compulsory insurance, every possible effort should be made to determine whether or not a plan can be developed that will strengthen the voluntary approach."

The AMA's stand declared that voluntary methods are meeting the challenge of an expanding aged population and will continue to meet the challenge if given the continued opportunity. Dr. Frederick C. Swartz, Chairman of the AMA Committee on Aging, stressed that "medical care is not susceptible to production line techniques."

Labor believes that insurance has certain characteristics which inevitably will keep it from being an adequate form of protection against the health costs of the aged. Congressman Joseph E. Karth, Fourth District (Ramsey County), Minnesota, a union advocate, replied in a form letter to many local doctors who expressed to him their opposition to the Forand Bill. He believes that "organized medicine in its social posture is many years behind the remainder of the country" and he pointed "specificially to the instances of the reluctant acceptance by the AMA some years ago of Blue Cross-Blue Shield and more recently of closed panel practice." He also stated, "I'm sure you would agree that even Whitaker and Baxter would be hard pressed to put across successfully to the public the image of organized medicine as a dynamic force in our society."

I think that we all believe that medicine in America is second to none and primarily due to the preservation of free enterprise, but we shall have to fight to keep it that way. Representative Forand and others consider that "organized medicine, frankly, has deliberately defaulted its responsibility." This I do not believe, but nevertheless, that is the challenge.

In conclusion, Representative Karth has given us food for thought when he stated, "It seems to me that as a physician and as an acknowledged leader in your community, you also have the solemn responsibility, together with your colleagues, to develop a health care plan for our aged population which would be professionally adequate, expeditious, economically realistic, administratively simple and responsive to needs of patients and doctors, and above all compassionate and jealous of the precious dignity of older human beings." Therefore, we must accept this challenge and responsibility individually and collectively.

Benjamin B. Boustead M.D.

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

MINNESOTA BOARD OF MEDICAL EXAMINERS HAS BUSY YEAR IN 1958

The Minnesota State Board of Medical Examiners licensed 362 physicians during the past year. The average number over the years has been 372; the largest number licensed was 420 in 1947. Dr. F. H. Magney, Secretary of the Board, disclosed this figure in a report presented to the 1959 House of Delegates of the Minnesota State Medical Association at its annual meeting.

Of the 362 licensed in 1958, eighteen were foreign-educated. A total of 150 foreign-educated physicians have been licensed in Minnesota from 1949 to 1958. There has been only one failure in that group. The failures elsewhere have been much higher. The Board believes the reason is that great care is used here in checking the credentials of the applicants. All foreign applicants have been interviewed personally and individually by the Board.

The candidate must first pass the basic science examination. He must spend two years in an accredited hospital in Minnesota. Also, a large number have been doing graduate work at the University of Minnesota and at the Mayo Foundation. Eleven were graduated in medicine from the University of Minnesota and six were graduated from other approved American medical schools. All of these graduates from approved American medical schools are practicing in St. Paul, Minneapolis, Duluth and Rochester, at the present time.

Nineteen graduates from foreign medical schools are practicing in smaller towns; seventeen are in the larger cities; fifteen are in state and county hospitals; two are in the armed forces; thirty-nine have left the state and the location of two is unknown. Thus, the medical population has been increased by only 150 after much work on the part of the Board and its staff. The processing of these applications is expensive and time consuming.

Medical Directory Listings

The total number of names in the 1958 directory was 8,941. Of this number 7,514 were physicians, 4,219 of whom resided in Minnesota; 139 were osteopaths as against 162 in 1928; one osteopath being licensed in 1958; 547 were chiropractors of whom thirty-three were licensed in 1958; ten midwives and sixty-three masseurs and masseuses. There were also 233 registered physical therapists of whom fifty-three were registered in 1958 by the Medical Board. There were also 435 public health nurses.

The material for this directory is supplied by the Medical Board. Publication has been taken over by the Department of Administration from the State Board of Health. The charge is $1.50 per copy. Three supplements a year are provided by the Board.

Physician Deaths

Eighty-three registered physicians died during 1958. Of these, sixty-one lived in Minnesota. The average age at death was 66.34 years in 1958 and 68.08 in 1957. There was one death at age twenty-eight from peptic ulcer and one death from an airplane crash. Four died in automobile accidents between the ages of forty-one and forty-six years; there were nineteen deaths between fifty and fifty-nine years and fourteen deaths between sixty and sixty-eight years. Heart disease was the cause of death in thirty-nine cases; cerebral hemorrhage in seven deaths; pulmonary disease in seven cases and five from cancer.

Legal Activities

The Medical Board and its staff participates in much investigating, legal and disciplinary work. During the past year there were thirteen court cases with fourteen persons being involved. Five were abortion cases; two were violations of the basic science law; four involved fraud in obtaining drugs and narcotics; two for selling drugs in a place other than a pharmacy and one case of maintaining an office with no basic science certificate. Thirteen defendants were found guilty. One case was taken under advisement.

There are thirty-five stipulations in force in Minnesota. Stipulation means that a physician has violated some law or subjected himself to the danger of a suspension or revocation of his license. If the offense is not too serious, the physician is

given the opportunity of signing a stipulation that he will correct the conditions that led to the charges against him. Twenty-five of these stipulations were terminated during 1958.

The licenses of two physicians were suspended in 1958. There were no revocations. The most frequent charges are violations of the narcotic laws, personal use of narcotic drugs, barbital compounds, and the excessive use of liquor.

Legislation

Several amendments were made to the Medical Practice Act by the Legislature this year, after prior approval by the Council of the Minnesota State Medical Association. The annual registration fee was increased to $5.00 per year. The money is needed to permit the Board to carry out its duties under the law. The examination fee was increased to $35.00 so that new applicants would help to pay the cost of processing the applications. Effective July 1, 1960, the law requires one year of graduate hospital training as a prerequisite to being licensed. The law now permits the Medical Board to issue a temporary permit valid between examinations to a qualified applicant. This will do away with the delay for an applicant between examinations given by the Board. The Board was also given discretionary power to admit to licensure a person from another state who is fully qualified and licensed in that state.

The Legislature also fixed the per diem of Board members at $50.00. The compensation of the Secretary of the Board was set at not to exceed $4,800 per year, with the Board given the authority to determine the exact amount.

The Governor recently appointed to the Board, Dr. R. O. Sather of Crookston and Dr. I. L. Oliver of Graceville, both of whom were nominated by the Council.

EIGHT THOUSAND NEW DOCTORS LICENSED IN UNITED STATES DURING 1958

Almost 8,000 new physicians were licensed to practice medicine in the United States during 1958, it was reported May 29 by the American Medical Association's Council on Medical Education and Hospitals. In its fifty-seventh annual report, the council said that this marks the sixth consecutive year in which more than 7,000 new physicians were licensed. Of the 7,809 new doctors, 6,155 were licensed through written examinations and 1,654 by endorsement of credentials. During the period, there were approximately 3,700 physician deaths reported to the American Medical Association, which reduces the overall gain in the doctor population to 4,109.

In all, 15,240 licenses to practice medicine were issued in 1958. Written examinations accounted for 7,315 licenses and 7,925 were given through reciprocity and endorsement of credentials. Of these, California issued the greatest number—2,205, New York was next with 1,584. Illinois, Ohio, Pennsylvania, and Texas each registered more than 500 doctors. Nine states—Alaska, Delaware, Idaho, Montana, Nevada, North and South Dakota, Vermont, and Wyoming—issued less than fifty licenses during the year. Among the territories and possessions, Puerto Rico licensed 107, Hawaii 44, Canal Zone 6, Guam and the Virgin Islands 2 each. The Council said there was an increase of 104 in the total number of licenses issued in 1958 over the previous year.

During the year, there were 8,633 applicants for licensure by written examination. Of these 7,268 passed and 1,365 failed. Among those examined were 5,692 graduates of approved medical schools in the United States, 168 from Canada, one graduate of an approved medical school in the United States which is no longer in operation, 2,567 from foreign schools, twenty-five graduates of unapproved medical schools in the United States which are no longer in existence, and 180 graduates of schools of osteopathy.

Twelve approved medical schools in the United States had no failures among their graduates who were examined. These include Stanford University, Chicago Medical School, University of Chicago, Boston University, Wayne State University, University of Mississippi, University of Missouri, University of Nebraska, Albany Medical College, University of Oregon, University of Pittsburgh, and the University of Utah.

The number of new licenses issued on the basis of geographical areas were: New England, 470; East North Central, 1,447; Middle Atlantic, 1,708; West North Central, 784; South Atlantic, 1,184; East South Central, 446; West South Central, 748; Mountain, 129; Pacific, 790, and territories and possessions, 103.

MEDICARE BENEFITS EXCEED $185 MILLION MARK

Medicare benefits paid to members of the uniformed forces from December 6, 1956, to June 30, 1959, have totaled $185,400,000. This amount includes $91,000,000 for hospital care and $94,000,000 for doctors' fees.

Medicare was established in 1956 by an act of Congress to pay for civilian medical care for dependent spouses and children of members of the Army, Navy, Air Force, Marines, Coast Guard, Commissioned Public Health Service, and Coast and Geodetic Service.

The Office for Dependents' Medical Care recently submitted its second annual Medicare report to Congress. This report revealed that in 1958, hospital admissions of military dependents totaled 664,000 compared with 651,000 in 1957.

Fifty-two per cent of the 1958 total entered private hospitals and 48 per cent in service institutions. Maternity cases involving some 264,000 deliveries accounted for 40 per cent of the admissions. Claims of physicians totaling $234,974 yielded an aggregate of $17,580,352 between July 1, 1957, and December 31, 1957. The figure rose sharply to 366,566 and $27,795,009 respectively during the first half of 1958. A sharp decline in physicians' claims during the second half of 1958 was noted. During this period, the number of claims dropped to 274,251 with an estimated dollar value of $21,342,488. This decline was due to curtailed benefits previously available to Medicare claimants.

States whose Medicare physician fees exceeded the multi-million dollar mark during the July to December, 1958, period include: California with $3,923,376 and Texas with $2,170,595.

Formal protests were made by a number of state medical associations against the restriction imposed on Medicare benefits in October, 1958. Principal objections included: interference with patients' free choice of physician; too abrupt a change in benefits and procedures; difficulty in administering changes; and imposition of additional paperwork burdens on the doctor.

Physicians and Medicare dependents frequently misinterpret the purpose of Medicare permit (DD Form 1251). This form is issued to dependents living with their sponsors when military medical facilities are not available or inadequate and it entitles the holder to authorized service only and not unlimited care by civilian physicians.

DOCTOR WINS FEDERAL TAX CASE

A Texas federal district judge has ruled that Dr. Sidney Galt, a senior partner in the Southwest Clinic Association in Dallas, need not pay income taxes as an individual on undistributed profits; but, rather, such profits should be taxable as if the Association were a corporation, rather than a partnership.

Some observers have expressed the opinion that an early Internal Revenue Service appeal of the decision of District Judge T. Whitfield Davidson may be expected.

The case climaxed more than four years of litigation between Doctor Galt and the Internal Revenue Service. Judge Davidson ordered refunded income taxes paid by Doctor Galt on the basis of partnership in the association which the Internal Revenue Service contended was a partnership. Doctor Galt contended that doctors belonging to the partnership should be taxed only on salaries and bonuses paid them and not on association profits. He said the undistributed profits should be taxed just like those of a corporation.

Dallas attorney, George Ray, pointed out that the decision was a precedent-setting income tax case which would affect doctors, lawyers, architects and others selling personal service. Attorney Ray further pointed out that Judge Davidson's decision will permit doctors to organize an association rather than partnerships and have all the benefits of a corporation under the federal income tax law. He further pointed out that pension funds and other benefit programs can be set up within the organizations.

CONVICTED NATUROPATH MAKES SUPREME COURT APPEAL

A Texas naturopath convicted of unlawful practice of medicine by a San Antonio jury has petitioned the United States Supreme Court to review his conviction.

The jury has prescribed a $500 fine and ordered the naturopath to serve a thirty-day jail sentence. Briefs filed with the United States Supreme Court indicate that the activities of Lonnie Keahey, N.D., began with his diagnosis of the pain of an undercover policeman attributable to "stomach gases." His treatment consisted of a potion drawn from shelf drugs. For this treatment, the under-cover policeman received a bill for $4.00.

The result—arrest and conviction of one naturopath.

HAWAII IS A HEALTHFUL STATE

Hawaii, our fiftieth state, has an excellent health record, reports the Statistical Bulletin of the Metropolitan Life Insurance Company.

The report points out that this excellent record reflects in a large measure advances in medical practice, improvement in environmental sanitation, and a general rise in living standards. The marked degree of control gained over the infectious diseases is an especially bright feature of the record. For example, tuberculosis mortality in the civilian population was down to the very low rate of 3.1 per 100,000 in 1957, a decrease of more than 50 per cent in two years and of about 95 per cent since 1940. The death rate from influenza and pneumonia in 1957, despite the widespread prevalence of upper respiratory infection that year, was only 25.6 per 100,000—half that recorded in 1940. At the same time, the principal communicable diseases of childhood (measles, scarlet fever, whooping cough, and diphtheria) and typhoid fever have been practically eliminated as causes of death.

Striking progress has been achieved in safeguarding infant life and making childbearing safer in Hawaii. The infant mortality rate in 1957 was 24 per 1,000 live births, compared with 44 in 1940. Furthermore, the loss of life in infancy is being increasingly concentrated in the first four weeks after birth, when mortality is least amenable to control. Currently, three fourths of the infant deaths in Hawaii occur during the first month; in 1940 the proportion was three fifths. Maternal mortality dropped from 2.4 per 1,000 live births in 1940 to 0.4 in 1957. During this period, the proportion of births occurring in hospitals rose from 70 to 99 per cent.

The leading causes of death in Hawaii are much the same as those in continental United States. Heart disease ranks first by a considerable margin, accounting for about a third of the total mortality in 1957. The cardio-vascular-renal diseases of the arteries—were responsible for nearly half the total. Cancer and other malignant neoplasms ranked second to heart disease, with one sixth of all deaths. Next in order of numerical importance were diseases of early infancy, accidents, and influenza and pneumonia.

Although accidents rank fifth at all ages combined, they outrank by a considerable margin every other cause at ages one to twenty-four years, being responsible for nearly a third of the total mortality in this age group. Nearly 45 per cent of the fatal accidents at ages one to twenty-four result from injuries in motor vehicle accidents. Beginning with ages twenty-five to forty-four, heart disease is the leading cause of death and cancer is second in rank. The proportion of all deaths attributed to heart disease rises from one quarter at ages twenty-five to forty-four to somewhat over one third at ages forty-five to sixty-four, and to nearly half at ages sixty-five and over. Cancer is responsible for about one fifth the total mortality at each of these age groups.

Longevity in Hawaii compares very favorably with that for continental United States, according to the life table for 1949-51, the latest available for Hawaii. The average length of life for men in Hawaii was 67.76 years, or two and one-quarter years more than the men on the mainland. The average for women was 71.29 years, or slightly above that for women in the United States.

HOW DO YOU RATE? SURVEY POINTS UP HOW M.D.'s STAND WITH PUBLIC

A recent survey by the Hartford County (Connecticut) Medical Society on what local citizens think of their doctors indicated that while people approve of the quality of medical care they receive, they have other opinions about the cost of it.

On the whole the survey turned up *favorable views on the availability of physicians* (81 per cent said they never had trouble getting a doctor when they needed one) and the competency of their physicians (91 per cent considered that the care rendered by their family doctor was either good or excellent).

In the matter of costs, 77 per cent thought doctors' charges were about right for office calls and 70 per cent believed that current home calls were reasonable. However *only 46 per cent considered surgical charges about right,* while 16 per cent (mostly in the lower income group) believed they were too high. More people (43 per cent) disapproved of prescription prices than approved (39 per cent). Views on whether or not hospital costs were too high ran about 50-50.

Although the trend in recent years has been toward billing patients by itemized statement, 52 per cent of the sample indicated they did not receive itemized bills from their doctors, while 39 per cent said they did. Strangely, only 28 per cent said they actually wanted their bills itemized.

One significant fact the survey turned up—and one which probably applies to other societies as well—was that only 40 per cent of those questioned had ever heard of the Hartford County Medical Society. Most of those who had were in the upper income group. Even more disturbing was the fact that *83 per cent had never heard of the society's emergency call service* which indicates that a good deal of publicity is in order for this phase of the organization's activities.

JAYCEES FOR HEALTH

Local Jaycee chapters throughout the country are again this year being supplied with *guides for community health activities.* The ten-phase program, prepared in co-operation with a special committee of the AMA, covers projects dealing with immunization, flouridation, health forums, recreation for mental hospitals, health services directories, accidental poisoning, handicapped children, health fairs, alcoholism and rabies. Suggested projects in each area are outlined in separate how-to-do leaflets available on request from the U. S. Junior Chamber of Commerce, P. O. Box 7, Tulsa 2, Oklahoma. Physician Jaycees should encourage their chapters to make use of the guides.

IN THE INTEREST OF BETTER PRESS RELATIONS

The Louisiana State Medical Society recently presented its first annual press award to the *New Orleans States-Item* for an editorial and news campaign to have stray dogs given to medical schools for scientific research.

The award was accepted by Editor Carl Corbin, Louisiana State Medical Society public relations chairman, Doctor Richard L. Buck, said in making the presentation "we salute you and the *States-Item* for the contribution your newspaper has made to the advancement of medical science."

Also singled out for recognition by the medical society was the weekly newspaper *Plaquemines Gazette* for "unrelenting opposition to socialism in general and socialized medicine in particular." The *Baton Rouge State-Times and Morning*

Advocate were mentioned by the state society for excellent coverage of medical news.

This is another example of what can be done by county medical societies to give credit where credit is due.

AMBULANCE INSPECTION HELD In order that Broome County, New York, residents could be assured of proper ambulance service in an emergency, the county medical society recently promoted an ambulance inspection day.

According to accounts of the project, fifteen ambulances from around the county gathered in a factory parking lot and underwent an examination by representatives of the medical society, Red Cross and police officers. Each satisfactorily equipped vehicle received a certificate from the chairman of the state medical committee on first aid and transportation of the injured.

Public acceptance of the project was considered overwhelming by its sponsors. Activities of the event were well covered by area press, radio and television, and the resulting public relations value was apparent. Advance notification of the event was given to ambulance agencies regarding inspection requirements. Reports show that all but one were able to secure the proper equipment in time to pass the test. Public recognition was given to the ambulance drivers, many of whom are volunteers.

ANNOUNCING VACATION SCHEDULES "Medical men need vacations, too" was the theme of an announcement placed in Dolphin County (Pennsylvania) newspapers to announce vacation schedules of members of the county medical society. The announcement went on to describe the arrangements made by members of the society to guarantee their patients adequate emergency medical care during their absence. Also listed in the announcement was the society's emergency call number.

OFFICE HOURS Patients do appreciate having office data in printed form for a quick reference. A number of county medical societies have prepared a white card (five by six inches) that lists the hours during which each doctor is on duty as well as home and emergency telephone numbers.

County societies which have adopted such a plan report that patient reception to this gesture is excellent.

Clinical Sessions and Annual Meetings

Also reported as highly successful is the policy adopted by physician groups in a number of areas throughout the nation who place signs—furnished by the county medical society—on their doors explaining that they were furthering their medical education by attending either a Clinical Session or a State Medical Association meeting.

Those who have observed the use of this method of informing patients have expressed the opinion that the plan boosted attendance at Clinical Sessions as well as improving doctor-patient relationships.

"IT'S A MATTER OF CHOICE" "It's a matter of choice"—a timely sound motion picture film which explains the facts about our social security system has been produced by the United States Chamber of Commerce.

The twenty-six-minute film clarifies the social security system as Congress intended it. Also explained in the film are the dangers of making the social security program a political football with benefits boosted each election.

One review of the film points out that in light of the current Forand Bill situation, the film has a particularly timely illustration of the American Medical Association's point of view.

Why not plan to book the film for your county medical society meeting or better yet, suggest the showing to a civic organization in your community.

For bookings of "A Matter of Choice," write to Modern Talking Picture Service, Inc., 3 East 54th Street, New York 22, New York. List a preferred and an alternate date. There is no charge for use of this film.

...WHEN YOU PRESCRIBE NEW

MORNIDINE™

(BRAND OF PIPAMAZINE)

A new drug with specific effectiveness in nausea and vomiting of pregnancy, Mornidine eliminates the ordeal of morning sickness.

With its selective action on the vomiting center, or the medullary chemoreceptor "trigger zone," Mornidine possesses the advantages of the phenothiazine drugs without unwanted tranquilizing activity.

Doses of 5 to 10 mg., repeated at intervals of six to eight hours, provide excellent relief all day. In patients who are unable to retain oral medication when first seen, Mornidine may be administered intramuscularly in doses of 5 mg. (1 cc.).

Mornidine is supplied as tablets of 5 mg. and as ampuls of 5 mg. (1 cc.).

DEPARTMENT OF HEALTH LISTS RESULTS OF ORAL POLIO VIRUS VACCINE STUDY

Twenty-five infants (born to mothers immunized during pregnancy with two doses of Salk vaccine) ranging in age from four days to six months, were fed living attenuated poliomyelitis virus type I (SM strain), type III (Fox strain), and type II (MEF_1 strain) at intervals varying from three to eleven weeks during 1957. Fourteen infants of less than two weeks in age were vaccinated against all three types of virus. All demonstrated satisfactory antibody response at approximately two months of age.

When the orally vaccinated group was compared to a similar group of infants inoculated with Salk vaccine, the antibody response to the attenuated virus was found to be as good or better for types I and III but poorer for type II. Evidence of spread to other members of the family exclusive of the father was determined by significant antibody rise or isolation of virus from the stool. Spread to siblings was sixty-eight per cent for type I, sixteen per cent for type II, and sixty per cent for type III.

A total of 551 persons (288 adults and 263 children) comprising 150 families in Como Village, southeast Minneapolis, were given orally administered vaccine in capsules at three-week intervals in a second study conducted in 1958. One-half received placebo and one-half received vaccine identical to that given to the infants except that the dosage of type II was increased.

The orally administered attenuated polioviruses used in this study are clearly effective as antigens for children. This effectiveness obviously extends to all three types. When measured by a crude bettering of an original antibody titer of less than four, these viruses were effective in inducing such a change in approximately eighty-five to ninety per cent of the participants. When measured by a stricter and (from the laboratory standpoint) a more significant criterion of at least a sixteen-fold rise in titer, the effectiveness is still apparent in approximately seventy per cent. The attenuated viruses used were like naturally occurring viruses in all respects except that they do not produce clinical disease.

Although the vaccine is less effective in adults, a trend is suggested in that the virus-fed group always had better conversion rates than the placebo-control group. When the upward trend of antibody titers in adults is measured for statistical significance on the basis of sixteen-fold increments, the difference in response between the placebo-control group and the virus-fed group are statistically significant for all types. While differences are not as great as those occurring in children, they are not accidental.

The Como Village studies stimulated a study now underway in Grove East Village, St. Paul. Its purpose is to determine if antibody production is as effective when all three types of virus are given at once as when each type is given separately. Half of the about 230 participants (comprising approximately sixty-five families) will get a single dose of trivalent liquid vaccine that includes the attenuated virus of all three types of polio in greater concentration than in previous tests. Feeding of vaccine is completed and laboratory testing is now in progress to determine antibody response.

In all three studies, stool and blood specimens were collected at appropriate intervals. There have been no untoward effects or clinical illnesses which could be attributed to the vaccines.

Plans have been made for a fourth study involving approximately 180 men at the St. Cloud Reformatory. The purpose is to determine whether gastric acidity plays a part in lessening the effectiveness of the oral vaccine in adults as compared to children and to study the pathogenesis of poliomyelitis. Like all previous studies, this is supported with grants from the Sister Elizabeth Kenny Foundation and Lederle Laboratories.

More than 1,000,000 doses of the live attenuated vaccine have been given to more than 550,000 people in Latin America to March 10, 1959. Of these, 250,000 have been given all three types with no bad effects.

HUMAN GENETICS COUNSELING PROGRAM AUTHORIZED

The 1959 Minnesota Legislature passed enabling legislation which will permit the Minnesota Department of Health to establish a human genetics program for counseling, education, and research on physical or mental abnormalities related to heredity. No funds were appropriated, but the act authorizes the State Board of Health to accept federal grants and gifts from private organizations or individuals to support work in human genetics. This law also provides for appointment of a nine-member advisory committee on human genetics by the State Board of Health.

Under the act, the State Health Department is authorized to collect and interpret data concerning human hereditary diseases, including the effect of increased radiation on heredity; conduct research on genetic problems; offer heredity counseling to families; and carry on a public information service.

. . . and one to grow on

A tiny tablet of REDISOL to stimulate the appetite — to help in the intake of food for growth.

REDISOL is crystalline vitamin B_{12}, an essential vitamin for growth and the fundamental metabolic processes.

Ideal for the growing child, the REDISOL tablet dissolves instantly on contact in the mouth, on food or in liquids.

Packaged in bottles hermetically sealed to keep the moisture out and to retain vitamin potency in 25 and 50 mcg. strengths, bottles of 36 and 100 — in 100 mcg. strength, bottles of 36, and in 250 mcg. strength, vials of 12.

Also available as a pleasant-tasting cherry-flavored elixir (5 mcg. per 5-cc. teaspoonful) and as REDISOL injectable, cyanocobalamin injection USP (30 and 100 mcg. per cc., 10-cc. vials and 1000 mcg. per cc. in 1, 5 and 10-cc. vials).

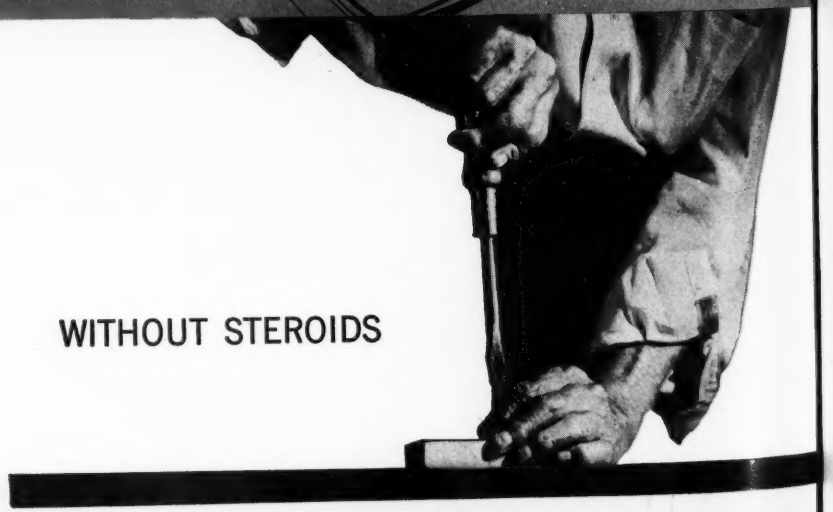
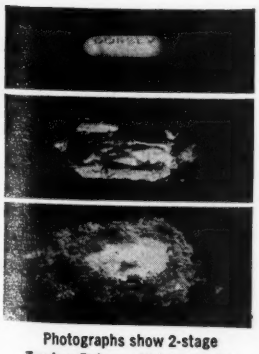
WITHOUT STEROIDS



In every arthritic state.. M

WITHOUT STEROIDS

WITHOUT STEROIDS



...te.. MAINTENANCE THERAPY WITHOUT STEROIDS IS FUNDAMENTAL

Sound, conservative therapy with salicylates has been consistently reaffirmed as basic, long-term maintenance therapy in the arthritides.

Buffered Pabirin provides superior maintenance therapy. It epitomizes fundamental long-term basic therapy since it can be given month after month without serious complications and with minimal problems to patient and doctor alike.

Buffered Pabirin is formulated to provide high and sustained salicylate blood levels. Each tablet consists of an outer layer containing a buffer (aluminum hydroxide), para-aminobenzoic acid, and ascorbic acid; a core of acetylsalicylic acid.

In the stomach, the outer layer quickly releases the buffer, which protects against nausea, dyspepsia and other gastrointestinal symptoms so frequently encountered with salicylates alone. The core of Buffered Pabirin then disintegrates rapidly, permitting rapid absorption of the acetylsalicylic acid for faster pain relief.

Photographs show 2-stage Tandem Release disintegration.

Each tablet contains:
Acetylsalicylic acid (5 gr.).....300 mg.
Para-aminobenzoic acid (5 gr.)....300 mg.
Ascorbic acid ..... 50 mg.
Dried aluminum hydroxide gel....100 mg.

All Buffered Pabirin is sodium- and potassium-free.

Dosage: Two or three tablets 3 or 4 times daily.

HUMAN GENETICS COUNSELING PROGRAM AUTHORIZED

(Continued from Page 1292)

The program will develop as funds permit through the department's division of special services, directed by Dr. A. B. Rosenfield.

The legislation was authored by State Senator Alf Bergerud, Minneapolis, as well as Representatives Clifton Parks, St. Paul; Sally Luther, Minneapolis; and Howard Ottinger, Chaska. It was passed by a unanimous vote of both the Senate and the House. The measure was actively supported by the Dight Institute of Human Genetics, University of Minnesota, and the Minnesota Human Genetics League. It is one of about twenty such centers in the nation, according to Dr. Sheldon C. Reed, director of the Dight Institute.

As the State Health Department's program in human genetics develops, the institute is expected to be able to expand its research and teaching programs in the medical school. The Health Department program will also provide heredity counseling to adoption and similar agencies. It will also give assistance to physicians through consultation on individual cases, seminars on medical genetics, and distribution of educational materials. The Department will work co-operatively with state and national agencies studying human genetics, including the U. S. Public Health Service and the U. S. Children's Bureau.

Meetings and Announcements

STATE

Minnesota Academy of General Practice, Fall Refresher, Radisson Hotel, Minneapolis, Minnesota, September 22-23, 1959. For reservations and further information, write: Matthew K. Plasha, M.D., Chairman, Coon Rapids Clinic, Coon Rapids, Minnesota.

Minnesota Public Health Conference, 1959 Program, Radisson Hotel, Minneapolis, Minnesota, September 24. Registration 8:00 a.m.; program begins 9:30 a.m.

NATIONAL

Academy of Psychosomatic Medicine, Sixth Annual Meeting, October 15-17, 1959 at the Sheraton-Cleveland Hotel, Cleveland, Ohio. For further information contact Dr. Bertram B. Moss, Suite 1035, 55 East Washington Street, Chicago 2, Illinois.

American College of Surgeons, Annual Clinical Congress, Atlantic City, New Jersey, September 28-October 2. Dr. Michael L. Mason, Secretary, 40 East Erie Street, Chicago 11, Illinois.

American Heart Association, Annual Meeting and Scientific Sessions, October 23-27, 1959, Philadelphia. Scientific Sessions scheduled for October 23-25 at Trade and Convention Center. Annual Meeting of the National Assembly, Hotel Bellevue Stratford, October 26-27. Information available from Minnesota Heart Association, 1821 University Avenue, St. Paul 4, Minnesota.

The annual course in Postgraduate Gastroenterology, sponsored by The American College of Gastroenterology, will be given at The Biltmore in Los Angeles, California, September 24, 25 and 26, 1959. For further information and enrollment, write to the American College of Gastroenterology, 33 West 60th Street, New York 23, New York.

The Academy of Psychosomatic Medicine has announced its Sixth Annual Meeting, October 15-17, 1959, at the Sheraton-Cleveland Hotel in Cleveland. For further information, write to Dr. Bertram B. Moss, Suite 1035, 55 East Washington Street, Chicago 2, Illinois.

The American Rhinologic Society will hold its fifth annual meeting in the Belmont Hotel, Chicago, October 10. The meeting will be preceded by a surgical seminar in the Illinois Masonic Hospital, Chicago, October 7-9. For further information write to Dr. Robert M. Hansen, Secretary, 1735 No. Wheeler Avenue, Portland 12, Oregon.

Association of American Medical Colleges, annual meeting, Edgewater Beach Hotel, Chicago, Illinois, November 2-4, 1959. For further information, write Ward Darley, M.D., Executive Director, 2530 Ridge Avenue, Evanston, Illinois.

Interstate Postgraduate Medical Association, Forty-fourth Scientific Assembly, Palmer House, Chicago, Illinois, November 2-5, 1959.

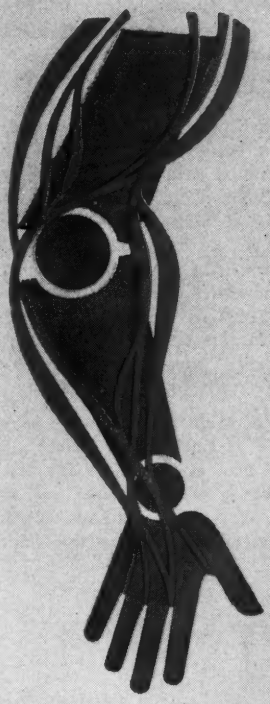
Institute of Industrial Medicine of New York University Post-Graduate Medical School, two-month course for physicians in Occupational Medicine. Presentations include Preventive Medicine, Administrative Medicine, Occupational Diseases, and Industrial Hygiene. The course will be a full-time, two-month course, September 14 through November 6, 1959, tuition—$375, field trip expense—$25. For applications, address Office of the Associate Dean, New York University Post-Graduate Medical School, 550 First Avenue, New York 16, New York.

Fourth National Cancer Conference, September 13-15, 1960, Minneapolis, Minnesota. Sponsored by the American Cancer Society, Inc., and the National Cancer Institute. Theme: Changing Concepts Concerning Cancer. For further information, write: Medical Affairs Department, American Cancer Society, 521 West 57th Street, New York 19, New York.

Mississippi Valley Medical Society, Twenty-fourth Annual Meeting, Chase Hotel, St. Louis, Missouri, September 29-October 1. Complete programs available from Dr. Harold Swanberg, M.D., Secretary, W. C. U. Building, Quincy, Illinois.

National Society for Crippled Children and Adults, Annual Convention, November 29-December 2, 1959, Palmer House, Chicago. For further information, write Miss Catharine Bauer, Director of Information, 2023 West Ogden Avenue, Chicago 12, Illinois.

Pan-Pacific Surgical Association, Eighth Congress, Honolulu, Hawaii, September 28 through October 5 in 1960. Further information and brochures may be obtained by writing to Dr. F. J. Pinkerton, Director General of the Pan-Pacific Surgical Association, Suite 230, Alexander Young Building, Honolulu 13, Hawaii.



A Postgraduate Course in Occupational Skin Problems will be given at the Institute of Industrial Health to be held at the University of Cincinnati, Cincinnati, Ohio, October 26-30, 1959. For further information, write to the Secretary, Institute of Industrial Health, The Kettering Laboratory, Eden and Bethesda Avenues, Cincinnati 19, Ohio.

Twelfth Annual Meeting of the American Association of Blood Banks, Edgewater Beach Hotel, Chicago, Illinois, November 4-7, 1959. For further information write, Office of the Secretary, American Association of Blood Banks, 30 North Michigan Avenue, Chicago 2, Illinois.

Twelfth Annual Conference on Electrical Techniques in Medicine and Biology, Sheraton Hotel, Philadelphia, Pennsylvania, November 10-12, 1959. For further information, write Dr. Herman P. Schwan, Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, Pennsylvania.

Eighty-seventh Annual Meeting of the American Public Health Association, Atlantic City Convention Hall, Atlantic City, New Jersey, October 19-23, 1959.

(Continued on Page 1300)

now... a new way to relieve pain and stiffness in muscles and joints

- Exhibits unusual analgesic properties, different from those of any other drug
- Specific and superior for relief of SOMAtic pain
- Modifies central perception of pain without abolishing natural defense reflexes
- Relaxes abnormal tension of skeletal muscle

SOMA™

N-isopropyl-2-methyl-2-propyl-1, 3-propanediol dicarbamate

In back pain, bursitis, sprains, strains, and bruises, whiplash and other traumatic injuries, inflammatory and degenerative muscle and joint complaints.

Many patients report they feel better and sleep better with SOMA than with any previously used analgesic or relaxant drug.

SOMA often makes possible reduction or elimination of steroids, salicylates, sedatives and narcotics.

RAPID ACTING. Pain-relieving and relaxant effects start within 30 minutes and last for at least 6 hours.

NOTABLY SAFE. Toxicity is extremely low. No effects on liver, endocrine system, blood pressure, blood picture or urine have been reported. Some patients may become sleepy on higher than recommended dosage.

EASY TO USE. Usual adult dose is one 350 mg. tablet 3 times daily and at bedtime.

SUPPLIED: Bottles of 50 white sugar-coated 350 mg. tablets.

Literature and samples on request.

Pan-Pacific Surgical Association, Eighth Congress, Honolulu, Hawaii, September 27 to October 5, 1960. For further information, write to The Pan-Pacific Surgical Association, Travel Headquarters, 36 South Wabash Avenue, Chicago 3, Illinois.

International Congress of Gastroenterology, sixth meeting, Leyden, Netherlands, April 20-24, 1960. Patron: His Royal Highness the Prince of the Netherlands.

United States Section, International College of Surgeons, two-week post-graduate course in General Surgery, in co-operation with the Cook County Graduate School of Medicine. Course begins November 2. Applications should be addressed to Mr. John W. Neal, Registrar, Cook County Graduate School of Medicine, 707 South Wood Street, Chicago 12, or to Doctor Ross T. McIntire, Executive Director, International College of Surgeons, 1516 Lake Shore Drive, Chicago 10, Illinois.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The Northern Minnesota Medical Association will meet September 11 and 12, in Duluth. All scientific sessions will be held at St. Luke's Hospital. The program will include a geriatric panel, including Doctors S. W. Arhelger, W. S. Neff, and L. R. Gowan. The Friday evening dinner will be held at the Northland Country Club.

SOUTHERN MINNESOTA MEDICAL ASSOCIATION

The Southern Minnesota Medical Association will meet September 14 at Mann Hall, Medical Science Building, Rochester, Minnesota. Registration will begin at 8:30 a.m. The opening session is scheduled for 9:00 a.m. Dr. Benjamin B. Souster, President of the Minnesota State Medical Association, will be the banquet speaker for the occasion.

MEETINGS OF THE AMERICAN COLLEGE OF SURGEONS

January

Sectional Meeting, The Brown Hotel, Louisville, Kentucky, January 21, 22, 23. Dr. Rudolf J. Noer, local chairman. Address inquiries to: Dr. H. P. Saunders, 40 East Erie Street, Chicago 11, Illinois.

February

Four-Day Sectional Meeting for Surgeons and Nurses, The Statler Hilton, (Surgeons' Headquarters) and Sheraton-Plaza (Nurses' Headquarters), Boston, Massachusetts, February 29, March 1, 2, 3. Dr. Claude E. Welch, local chairman. Dr. Anne Kibrick, chairman, nurses program. Address inquiries to: Dr. H. P. Saunders, 40 East Erie Street, Chicago 11, Illinois.

March

Sectional Meeting, The Broadmoor, Colorado Springs, Colorado, March 21, 22, 23. Dr. Edward H. Vincent, local chairman. Address inquiries to: Dr. H. P. Saunders, 40 East Erie Street, Chicago 11, Illinois.

Sectional Meeting, Sheraton-Portland Hotel, Portland, Oregon, March 28, 29, 30. Dr. Millard S. Rosenblatt, local chairman. Address inquiries to: Dr. H. P. Saunders, 40 East Erie Street, Chicago 11, Illinois.

April

Sectional Meeting, Hotel Leamington, Minneapolis, Minnesota, April 11, 12, 13. Dr. Horace G. Scott, local chairman. Address inquiries to: Dr. H. P. Saunders, 40 East Erie Street, Chicago 11, Illinois.

Sectional Meeting, Kahler Hotel, Rochester, Minnesota, April 14. Dr. Edward Starr Judd, Jr., and Dr. Joseph H. Pratt, co-chairmen. Address inquiries to: Dr. H. P. Saunders, 40 East Erie Street, Chicago 11, Illinois.

October

Clinical Congress, San Francisco, California, October 27-November 1.

POSTGRADUATE COURSES ON DISEASES OF THE CHEST

The Council on Postgraduate Medical Education of the American College of Chest Physicians will present the following postgraduate courses this fall:

Clinical Cardiopulmonary Physiology, Fourteenth An-

DBI

trade mark, brand of Phenformin

the "full-range" oral hypoglycemic agent... lowers blood sugar in mild, moderate, and severe diabetes, in children and adults

FOR MORE DEPENDABLE RESPONSE, start your patients on DBI—entirely different from the sulfonylureas in chemical structure, mode of action and spectrum of activity... usually effective in low dosage range (50 to 150 mg. per day).

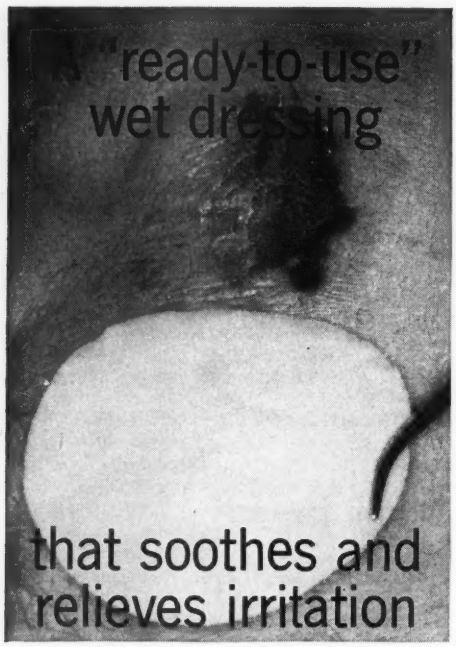
3 out of every 4 stable adult diabetics are satisfactorily and comfortably regulated with DBI.

2 out of every 3 brittle diabetics (juvenile or adult) enjoy better stabilization and easier management with combination of DBI and injected insulin. The smooth, gradual onset of blood-sugar lowering action helps prevent dangerous shifts between hypoglycemic reactions and hyperglycemic ketoacidosis.

sulfonylurea failures—secondary failures and primary resistant patients may respond to DBI alone, or combined with a sulfonylurea.

no clinical toxicity in over 3000 patients studied closely for varying periods up to nearly three years.

On a "start-low-go-slow" dosage pattern, DBI is relatively well tolerated. Gastrointestinal reactions occur most frequently in dosages exceeding the practical maximum 150 mg. daily, but abate promptly upon reduction of dosage or withdrawal of DBI.



The physician prescribing DBI should be thoroughly familiar with its indications, dosage, possible side effects, precautions and contraindications, etc.

DBI (N^1-β-phenethylbiguanide HCl) is available as white, scored tablets of 25 mg. each, bottle of 100.

Write for detailed literature.

NEW YORK UNIVERSITY ANNOUNCES SPECIAL COURSES

Air Pollution

The problems of the sources, effects and control of community air pollution will be treated in an intensive two-week course, "Air Pollution," offered by the New York University Post-Graduate Medical School in cooperation with the New York University College of Engineering from November 30 through December 11, 1959.

Radiological Health

The Department of Industrial Medicine of the New York University-Bellevue Medical Center Post-Graduate Medical School offers five courses in radiological health starting in October, 1959.

The courses are intended for persons already trained in one of the physical, engineering, biological or medical sciences who require a comprehensive introduction to the new techniques and methods associated with radiological hazard evaluation. The courses are as follows:

Introduction to Radiological Health.—Full time, October 12-23, 1959. For persons having responsibilities connected with the health and safety of personnel in installations using sources of ionizing radiation.

Radiological Health Laboratory.—Full time, October 26-November 6, 1959. A series of experiments designed to furnish a familiarity with the most important categories of nuclear detection apparatus and techniques of measurement.

Radiochemical Analysis.—A two-week intensive course, November 9-20, 1959, covering the techniques of radiochemistry and counting required for the determination of radioisotopes in biological and environmental samples.

Medical and Public Health Control of Ionizing Radiation.—Full time, March 7-18, 1960. Primary emphasis is on the biological effects of radiation and medical control programs. Specifically designed for public health officials, physicians, and others with biological interests.

Radiation Hygiene Measurements.—A four-week intensive course, April 18 through May 13, 1960, offering laboratory instruction in surveying, monitoring and sampling procedures for persons having some acquaintance with nuclear measurement principles.

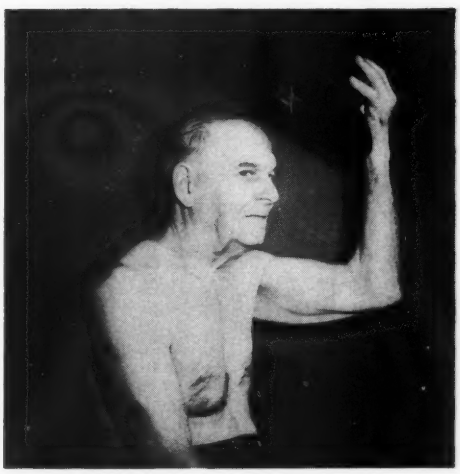
Postgraduate Courses

New York University-Bellevue Medical Center's Post-Graduate Medical School offers the following post-graduate courses:

(Continued on Page 1304)

For arthritic M.S.: full corticosteroid benefits from new Gammacorten™

Patient M.S., 81, at the time of the first visit was in severe pain and very uncomfortable. Complained of swelling of wrists, legs and various joints; pain and stiffness in cervical area and lower spine; pain, swelling and limited motion in the fingers; slight ulnar deviation of the hand. M.S. demonstrates position necessary to put on his hat (motion was so restricted that he could not comb his hair).



Treatment and Result: After 36 hours of GAMMACORTEN therapy, M.S. had "complete relief." Joint swelling had decreased, pain was almost absent, range of motion had increased dramatically. At the end of the first week of GAMMACORTEN he was free of discomfort and able to return to his job as a porter. M.S. could put on his hat normally, could comb hair; joint function near-normal after first week.

Gammacorten™
(dexamethasone CIBA)

- potent, effective corticosteroid
- profound anti-inflammatory activity
- minimal side effects

From the files of a practicing physician. Photographs used with permission of the patient.

SUPPLIED: GAMMACORTEN Tablets, 0.75 mg. (pink, scored).

Minnesota Blue Shield

On July 17, 1959, a representative of the National Association of Blue Shield Plans appeared before the House Ways and Means Committee to present the following facts illustrating the efforts which have been made by the majority of Blue Shield Plans to develop programs of voluntary health care coverage for senior citizens.

At the present time, twenty-four of the sixty-five Blue Shield Plans in operation in the United States, representing one-third of the total United States Blue Shield membership, offer non-group coverage to those over sixty-five. In addition, there are four more plans, embracing 17 per cent of the total Blue Shield membership, with programs approved but not actually in effect. There are twenty-five Plans with 41 per cent of total Blue Shield membership that have programs in various stages of development. Thus, Blue Shield Plans which have enrolled 92 per cent of the 40,681,000 present Blue Shield subscribers in the United States, already have or are currently developing special programs for this segment of the population.

Not unlike many other Plans, Minnesota Blue Shield, since its inception in 1947, has provided non-group coverage for medical-surgical care rendered senior citizens, regardless of age, whose contracts were in effect on their sixty-fifth birthday. At the present time, approximately 60,000 persons of age sixty-five or over are enrolled under Minnesota Blue Shield. However, there are more than 200,000 additional Minnesotans over age sixty-five who are not presently enrolled with the Plan. To assure this group of the availability of Blue Shield coverage and culminated by the approval of the Minnesota State Medical Association at its meeting in May, Blue Shield developed a voluntary health care program for the senior citizens of Minnesota. It is anticipated that applications will be accepted on a trial basis during the month of October, 1959.

In Memoriam

EDGAR W. BEDFORD

Dr. Edgar W. Bedford, Minneapolis physician and surgeon since 1920, died June 23, 1959, while vacationing in San Francisco. Doctor Bedford was seventy-two years old at the time of his death.

A native of Sheboygan, Wisconsin, he graduated from the University of Wisconsin and Rush Medical College in Chicago. Doctor Bedford was a veteran of World I.

Doctor Bedford was a member of the Hennepin County Medical Society, the Minnesota State Medical Association, and the American Medical Association.

He was on the staffs of Doctors Memorial and St. Barnabas Hospitals.

Survivors include his wife, Gladys; a son, Dr. Fred Bedford, Norwood, Colorado; two daughters, Mrs. Paul Sparso, Medford, Oregon, and Mrs. Martin Grady, Minneapolis, and six grandchildren.

CHARLES PERN ROBBINS

Dr. Charles Pern Robbins, Winona physician for more than sixty years, died July 15, 1959. Doctor Robbins, who established and operated the first x-ray department at the Winona General Hospital, served as county and school physician and was the first president of the Winona County Public Health Association. He was eighty-nine years of age at the time of his death.

Doctor Robbins was a native of Burlington, Iowa. He entered the Baptist College two years after graduating from Burlington High School in 1888. He graduated cum laude from Jefferson Medical College in Philadelphia. He began medical practice in Saginaw, Michigan, before becoming assistant surgeon in Los Angeles National Soldiers Home for one year. The following year, he took a four-month course in surgery at New York Post-Graduate Hospital. In 1896, he came to Winona, where he practiced medicine ten years and was on the staff of Winona General Hospital.

In 1906, he went to Europe to study under specialists. Doctor Robbins then made his decision to specialize in internal medicine and practiced in Winona for one year before going abroad to study.

In 1947, he was elected to an honorary fellowship in the American Medical Association. He also received a certificate of recognition for fifty-three years of service as an alumnus of Jefferson Medical College.

In 1940, he was made an honorary life member of the Minnesota State Medical Association, and in 1947, he was made an honorary life member of the Winona County Medical Society. He was an honorary member of the Winona General Hospital staff.

Doctor Robbins was a member of Winona Lodge 18, AF & AM, the Scottish Rite, the American Legion, the Arlington Club, the Winona County Medical Society, the Minnesota State Medical Association, and the American Medical Association.

Doctor Robbins is survived by his wife, Helen.

PHENAPHEN® PLUS

Phenaphen Plus is the physician-requested combination of Phenaphen, plus an antihistaminic and a nasal decongestant.

Available on prescription only. Robins

each coated tablet contains:	Phenaphen
Phenacetin (3 gr.)	194.0 mg.
Acetylsalicylic Acid (2½ gr.)	162.0 mg.
Phenobarbital (¼ gr.)	16.2 mg.
Hyoscyamine Sulfate	0.031 mg.
plus	
Prophenpyridamine Maleate	12.5 mg.
Phenylephrine Hydrochloride	10.0 mg.

Improvement and Release Following Prefrontal Lobotomy

The increased use of tranquilizing drugs has reduced the necessity of attempting to control some psychotic patients with the operation known as prefrontal lobotomy. All psychotic persons, however, do not respond favorably to medical treatment of this kind. The authors present a series of 38 male and 45 female patients operated upon between 1941 and 1956. Critical analysis of their data indicates that a significant number of these patients are improved and able to be released from institutional control following this type of surgery.

GORDON W. OLSON, Ph.D.
DONALD B. PETERSON, M.D.
Anoka, Minnesota

Dr. Olson is chief psychologist and Dr. Peterson is superintendent of the Anoka State Hospital.

THE surgical procedure known as prefrontal lobotomy, which severs fibers connecting the prefrontal area and deeper structures within the brain, was hailed some years ago as a beneficial procedure in various psychic conditions including obsessive compulsive neurosis, schizophrenia, and the patient with intractable pain. The common denominator of action seems to be an alteration of the patient's psychic reactions so that, although the basic obsessions, the frightening and disturbing delusions, or the intractable pain are apparently still present, the meaning and the appreciation of the disturbing element is diminished, and the patient is freed from his preoccupation with the disturbing factors. Through this procedure, many patients have been enabled to leave the psychiatric hospital and to take up useful lives. Since the advent of the tranquilizing drugs which

have had a marked influence on such conditions, the use of lobotomy has been markedly decreased and indeed in some quarters, may be said to be in disrepute. Nevertheless, the procedure is still utilized and indeed, its use will probably increase as the pool of patients who have not benefited from tranquilizers increases.

The degree of interest in this procedure varies directly with the physicians' degree of responsibility for the treatment of the psychotic.

Since the family physician is apt to be consulted by the next of kin who have been asked to consent to the surgery, it is believed that the subject matter of this paper is of general interest and contains useful information.

Although many studies have been published regarding the efficacy of prefrontal lobotomy, direct comparison among these studies is difficult because of geographical and individual differences in rationale for the surgery, diagnostic concepts, and manner of classifying and reporting the data. For this reason, this study concerned itself only with the more gross variables to assess local molar results for contribution to the general fund of information available on lobotomy.

Anoka State Hospital is a suburban 1100 bed psychiatric hospital, approximately sixty beds of which are located on the intensive treatment and admissions service. There is about 50 per cent monthly turnover on this service. In some cases the surgery was performed at other hospitals and the patient transferred to Anoka at a later date.

Method

The series contained thirty-eight males and forty-five female subjects operated upon between 1941 and 1956. The age range was twenty-two to sixty-six years and the mean was 42.34 years; length of hospitalization ranged from two months to thirty-one years with a mean of 6.95 years. The number of lobotomy operations performed per year in this sample increased steadily from a single operation the first year to sixteen operations during the last year. Forty-three (52 per cent) were operated upon between 1954 and 1956. In this sample, sixty-six patients (80 per cent) were diagnosed as schizophrenia, five as manic-depressive, ten as neurosis, one as chronic brain syndrome, and one as mentally deficient. The one mentally deficient patient had been transferred to Anoka from a state school for mental defectives two months before the operation. A severe behavior problem, he demonstrated considerable assaultive and destructive behavior while at Anoka. Although diagnosed as mental defective without psychosis, his behavior was such that others might well have made a diagnosis of psychosis with mental deficiency. There was no control group since an attempt to find patients who have been considered for lobotomy, but upon whom the operation was never performed for medical reasons or for lack of permission, resulted in gathering only a few acceptable cases.

In essence, the study concerned the relationships of five independent variables (age, length of hospitalization, diagnosis, rationale and sex) to two dependent variables (improvement and disposition). In addition it was possible to establish the number of behavioral incidents in which a portion of this sample was involved before and after lobotomy.

Definitions of terms used throughout this report are as follows:

Improvement refers to the physician's judgment as to whether the patient was in general more manageable and/or more comfortable than before the operation. The physician's rating was dichotomous, involving only the categories improved and unimproved.

Disposition refers to the location of the patient at the time of the study. The categories were: (1) still hospitalized; (2) transferred; (3) deceased; (4) discharged. Patients on provisional discharge were classified as discharged while those on brief visit were considered hospitalized. (In Minnesota, discharge becomes automatic after twelve months of provisional discharge unless extended for cause or unless the patient is readmitted.)

Length of Hospitalization (LH) refers to the number of months from the date of first admission to any Minnesota state hospital to the date of lobotomy. It includes time spent out of the hospital during unsuccessful attempts at provisional discharge.

Rationale refers to one author's opinion (G.W.O.) as to whether the lobotomy was intended primarily to alleviate severe distress or to reduce acting-out behavior. The opinion was based upon prelobotomy history and nursing notes; the

classifications employed were: (1) management; (2) management and comfort; (3) comfort.

Diagnosis was the formal determinate diagnosis listed for the patient in the medical records section of the hospital.

Age refers to the age of the patient at the time of surgery.

In the statistical analysis of the data, age and LH were treated as continuous data and the *t* test employed; the other variables were treated as frequency data and the X^2 test was used.

TABLE I. PHYSICIANS' RATINGS OF IMPROVEMENT FOLLOWING LOBOTOMY

Rating	Male		Female		Both	
	No.	%	No.	%	No.	%
Improved	25	66	37	82	62	75
Unimproved	13	34	8	18	21	25
Total	38	100	45	100	83	100

Results

Improvement.—Improvement was found to be grossly related to three variables: disposition, sex and LH. There was a significant relationship ($p < .01$) between the rating of improvement and release from the hospital following lobotomy. Only one unimproved case was subsequently discharged from the hospital, and this was for deportation to another state, presumably for further care. There was a marked tendency ($p < .10$) for females to have rated as improved more often than males (Table I). When the sexes were matched for LH, the difference in proportions of improved and unimproved was more pronounced ($p < .05$).

The average length of hospitalization prior to surgery was 5.62 years for the Improved group and 9.39 years for the Unimproved group ($p < .05$).

Disposition.—Disposition was found to be significantly related to four variables: improvement (as discussed above), LH, rationale, and diagnosis. Of the original eighty-three subjects, twenty-six had been discharged, forty-nine were still hospitalized, eight had been transferred to other hospitals. There were no deaths. Since the post-transfer status of eight patients was unknown, the following results pertain only to seventy-five patients.

The average age for the Discharge group was 44.31 years compared with 42.21 years for the Still Hospitalized group. The average LH prior to surgery was 2.06 years for the Discharged group and 8.73 years for the Still Hospitalized group ($p < .001$). The relationship of LH to disposition and to improvement is shown in Table II.

TABLE II. RELATIONSHIPS OF POST-LOBOTOMY DISCHARGE RATE AND POST-LOBOTOMY IMPROVEMENT TO LENGTH OF HOSPITALIZATION PRIOR TO LOBOTOMY

Rating	Years Hospitalization Prior to Lobotomy						
	½	1	2	3	5	10	10
Improved (%)	100	71	82	75	88	73	58
Discharged (%)	80	67	36	50	38	11	0

The disposition was significantly different for the two rationale employed ($p < .001$), when excluding the middle category of "management and comfort." At the time of the file search, two of thirty-one patients lobotomized for "management" reasons were on discharge compared with sixteen out of twenty-four patients operated upon for "comfort" reasons. When the "comfort" and "management" groups were matched for LH and diagnosis, the difference remained significant ($p < .05$) with two out of eleven of the "management" group and ten out of fourteen of the "comfort" group in the discharge category.

Evaluation of the effect of specific diagnosis upon disposition was difficult since so few subjects fell in each of the nonschizophrenic groups. There was a significant difference ($p < .01$) for disposition of psychotics and neurotics, with eighteen out of sixty-five psychotics having been released compared with eight out of ten neurotics.

Untoward Incidents.—In-hospital observations of behavior were available on nineteen subjects covering a period of one year prior to surgery and two years following surgery. Other subjects had transferred in less than one year before surgery or transferred out or discharged before two years postsurgery. The total number of untoward incidents for these nineteen subjects was fifty-seven for the twelve months preceding surgery, twenty-six for the first year following surgery and twenty-eight for the second year after lobotomy. From the preoperative period to the *second* postoperative year, twelve subjects showed a decrease in the number of incidents, three subjects showed the same number of incidents as before lobotomy, and four subjects manifested an increase (sign test $p < .04$).

Discussion

One of the more significant findings was the clear cut relationship of length of hospitalization and subsequent discharge. This finding corroborates several other studies[1,2,3] but is not interpreted as evidence for the lobotomy as a procedure to be employed early in the patient's illness. In the absence of a control group, it is uncertain to what extent the lobotomy contributed to the greater number of remissions in the short-term patients. Patients hospitalized for longer periods of time are those likely to have proven more refractory to longer courses and more varied forms of therapy than the short-term patient. Perhaps some portion of the short-term patients would have responded to sustained or repeated trials of another therapy. In short, the greater discharge rate among the short-term patients probably reflects in part a greater amenability to treatment *in general* than that found in the long-term patients.*

Further, the criterion of discharge from the hospital is complex and involves far more than the degree of "health" of the patient. It is generally felt that the amount of interest and understanding of the potential environment is of considerable importance in the determination of the patient's discharge and adjustment, and although these things may have been initially equal for the short and long term hospitalization groups, it is likely that family and associates retain more interest in the patient hospitalized one or two months or years than in the patient hospitalized twelve to fifteen years or more. In addition, it is plausible that some patients became "adapted" to the hospital after a decade of hospitalization, and few feel that the lobotomy restores social motivation; indeed, many long term patients actively resist discharge.

It was shown that the "management" type of patient in this sample had a longer LH and was less likely to be discharged following lobotomy than was the "comfort" type of patient. Beyond the obvious inference that the surgery may have been less effective in reducing acting-out behavior than in relieving subjective distress, sociological and administrative factors undoubtedly also operated. These involve the possibilities that the community may have offered something less than a welcome to the formerly assaultive individual, and the hospital may have been less willing to proffer a discharge to patients with such histories.

It was found that females received more ratings of "improved" than did the males. We have no clear cut interpretation of this but we do note that this finding is consistent with several other studies of lobotomy follow-up.[3,4]

*We have noted that a few obsessive-compulsive patients not included in this series have responded well to lobotomy in spite of very long periods of prior hospitalization. It may be that the LH factor is of less prognostic importance in this disorder specifically, or in the neuroses in general, than for the psychoses.

Summary

This study involved an analysis of the relationships of five independent variables (age, sex, length of hospitalization, diagnosis, and rationale) to lobotomy outcome, where outcome was defined by the physician's rating of improvement and by hospital release. The effect of surgery upon the number of behavioral upsets over a period of one year pre-lobotomy and two years post-lobotomy was also studied. From the results we concluded the following:

1. Length of hospitalization prior to lobotomy was closely and inversely related to outcome, both in terms of improvement and release, but was more closely related to the latter.
2. Specific diagnosis was not predictive of either improvement or release, but neurotics as a group had a significantly greater release rate than did psychotics as a group.
3. Assaultive and destructive behavior was reduced following lobotomy and this reduction was sustained by the group for at least two years.
4. Patients who demonstrated assaultive or destructive behavior pre-lobotomy were less likely to be released after lobotomy than were those who demonstrated self-punishing behavior, but the groups were equally likely to be rated as improved.
5. Females were more likely than males to be rated as improved following the surgery, but they were no more likely to be released from the hospital.

Congenital Hypoplastic Anemia Associated with Multiple Congenital Anomalies (Fanconi's Syndrome): Report of Two Cases

When confronted by a child with congenital anemia associated with multiple congenital anomalies, such as microcephaly, abnormal cutaneous pigmentation, retarded growth, skeletal deformities, strabismus and hyperactive reflexes, the physician should recognize the probability of Fanconi's syndrome. This paper presents two such cases.

Rochester, Minnesota

From the Mayo Clinic and Mayo Foundation, part of the Graduate School of the University of Minnesota, Rochester, Minnesota.

CONGENITAL hypoplastic or aplastic anemia associated with multiple congenital abnormalities during infancy and childhood is uncommon. In reviewing the literature, we were able to find only forty-one cases of such a combination.

In 1927, Fanconi[1] first reported this combination. He described three brothers, aged five, six and seven years, respectively, each of whom had anemia, thrombocytopenia, increased pigmentation of the skin, microcephaly without mental impairment, retarded growth, testicular hypoplasia, exaggerated deep tendon reflexes and convergent strabismus. Necropsy revealed hypoplasia of all elements of the bone marrow. A moderate number of "megaloblasts" were present in the peripheral blood of one patient. Fanconi regarded this syndrome as a "familial pernicious-like anemia."

Cases of Fanconi's syndrome occurring both in

families[2-7] and sporadically[8-11] have been reported since the first description. We recently encountered two patients with this disorder.

Report of Cases

Case 1.—A six-week-old white girl was brought to the Mayo Clinic because of rectal bleeding of four and a half weeks' duration. She was the product of a full-term gestation and normal delivery. Her weight at birth was 6 pounds and 11 ounces (3 kg.). Except for bilateral deformity of the forearms, nothing unusual was noted at birth. The postnatal period was uneventful until she was ten days of age, when rectal bleeding commenced.

Both parents were living and well; the patient was their only child. There was no history of a similar condition in the family.

Examination at the clinic revealed a poorly developed, thin baby with pronounced pallor and poor cutaneous turgor. Her rectal temperature was 100° F., and her weight was slightly more than 5 pounds (2360 gm.). The circumference of the head was 14 inches (36 cm.) and that of the thorax was 12 inches (30 cm.). Multiple ecchymoses of both elbows and severe radial deviation of the wrists were noted (Fig. 1, left). Both radii were absent. Each hand contained five digits. The liver and spleen were not palpable, nor was lymphadenopathy noted.

Laboratory Data.—Results of urinalysis were normal. The initial values for hemoglobin and erythocytes were 4.9 gm. per 100 ml. of blood and 1,680,000 cells per cubic millimeter, respectively. The leukocytes, at the time the patient was admitted, numbered 32,500, with 57 per cent lymphocytes, 8 per cent monocytes, 29 per cent neutrophils, 4 per cent eosinophils and 2 per cent basophils; there were three normoblasts per 100 leukocytes. Reticulocytes ranged from 2.8 to 12.6 per cent of the erythrocytes. The platelet counts ranged from 25,000 to 82,000 (the normal value in our laboratory is 100,000 to 250,000). The bleeding time was seven and a half minutes; the Quick prothrombin time was 18 seconds (normal in our laboratory is 17 to 18 seconds). A smear of the blood showed a leukemoid reaction with immaturity to the stem cell, as well as anisocytosis, polychromasia and basophilic stippling of the erythrocytes, and large atypical platlets. The anemia was considered to be normocytic and normochromic in type.

Smears of bone marrow from the tibia disclosed pronounced suppression of erythropoiesis, with only a rare late normoblast seen (see Table I). Myelopoiesis was active and was shifted to the left. Fixed sections of marrow were somewhat hypercellular; normoblasts and megakaryocytes were not identified.

Roentgenograms showed congenital absence of the radius of each forearm, with a congenital deformity at the wrists (Fig. 1, right). Flexion deformities of the fingers were noted, and the anterior aspect of the ulna showed some cortical thickening bilaterally.

Course.—The patient received a total of 480 ml. of blood in multiple transfusions. She continued to pass bloody stools at intervals during her stay in the hospital, and ecchymosis occurred at the sites of venipuncture.

Administration of ACTH (acthar gel) in a dose of 150 mg. per square meter of body surface per day was begun on the twelfth day of hospitalization and was continued for 14 days until she died, apparently in peripheral shock. The use of ACTH did not appear to alter either the clinical course or the blood picture.

Pathologic Findings.—Necropsy disclosed a hemorrhagic ulcer of the ascending colon, measuring 3.5 by 3 cm. Zones of petechial hemorrhage were present throughout the small intestine and in the hepatic flexure of the ascending colon. The spleen and liver were normal. The spleen contained some areas of myeloid metaplasia but, considering the age of the patient, these were not considered unusual. Fixed sections of vertebral bone marrow showed active left-shifted granulopoiesis but little evidence of erythropoiesis; only a rare megakaryocyte was noted.

Case 2.—A 13-month-old white boy was admitted to the hospital because of anemia since birth. The antenatal, natal and postnatal course was uneventful. At birth, it was noted that the baby was pale and had a small head. He smiled at two months of age, grasped objects at five months, sat up alone at eight to nine months and pulled himself up to a standing position at ten months of age.

The patient was the only child of his parents, and the family history was not remarkable.

At two months of age, he had been hospitalized for blood transfusions because of severe anemia. The anemia had persisted, requiring periodic transfusions. No bleeding tendency was noted.

Examination revealed a pale, microcephalic, alert baby. The external ears were deformed and low on both sides; they protruded laterally and rolled on themselves. His rectal temperature was 100° F. He weighed 15¼ pounds (6.9 kg.) and was 27½ inches (69 cm.) tall. The blood pressure was 110 mm. of mercury systolic and 53 mm. diastolic. The pulse rate was 120 beats per minute. The circumference of his head was 14 inches (36 cm.) and that of the thorax was 16 inches (41 cm.). His anterior fontanel was closed. The liver and spleen were not palpably enlarged, and no lymphadenopathy was noted. The deep tendon reflexes were hyperactive. Clubfoot was present on the left. Cutaneous pigmentation was absent. The testes were palpable in the inguinal canals.

Laboratory Data.—Urinalysis showed nothing abnormal. The value for hemoglobin was 3.8 gm., and the erythrocytes numbered 1,240,000. The leukocyte count was 6,700, with 64 per cent lymphocytes, 2 per cent monocytes and 34 per cent neutrophils. The reticulocyte count was 0.3 per cent. Platelets numbered 120,000. The blood was group A and Rh positive. The Coombs test gave normal results. Direct-reacting serum bilirubin was absent; the indirect-reacting component measured 0.7 mg. per 100 ml. Smears of peripheral blood revealed

normocytic and slightly hypochromic erythrocytes; polychromasia was absent.

Volumetric study of the bone marrow revealed the following percentages: 1 per cent fat, 85 per cent plasma, 2 per cent myeloid-erythroid cells, 12 per cent erythrocytes. Fixed sections of bone marrow were hypocellular, with practically no normoblasts present (see Table I).

Roentgenograms of the head revealed a small calvarium as compared to the size of the facial bones; the suture lines were not closed. Roentgenograms of the thorax were normal.

Subsequent information obtained from his home physician indicated the patient was still alive at the age of 5 years. He has required blood transfusions at approximately six-week intervals.

TABLE I. DIFFERENTIAL CELL COUNTS OF BONE MARROW IN TWO CASES OF FANCONI'S SYNDROME

Type of Cell	Per Cent Incidence	
	Case 1	Case 2
Neutrophils	21.8	23.0
Lymphocytes	7.0	41.4
Monocytes	1.6	3.6
Eosinophils	9.6	2.6
Basophils	0.4	0.0
Metamyelocytes	12.2	8.6
Late myelocytes	16.2	9.2
Early myelocytes	14.6	4.4
Progranulocytes	7.2	2.4
Blast cells	2.8	2.2
Immature lymphocytes	0.0	1.4
Pronormoblasts	0.6	0.2
Basophilic normoblasts	1.4	0.2
Polychromatic normoblasts	3.6	0.6
Orthochromatic normoblasts	1.0	0.2

Comment

Chappell[12] reported a case of pancytopenia with hypoplasia of the bone marrow and multiple congenital anomalies in a boy six weeks of age; the presenting symptom in this case was not pallor or hemorrhage but transposition of the external genitalia, for which plastic surgery was requested. The patient was said to appear generally healthy, but he had multiple skeletal abnormalities. Baumann's[13] patient, who died at the age of five years, was noted to have pallor at four months and purpura at thirteen months of age.

In Fanconi's syndrome, multiple genetic mechanisms apparently are altered simultaneously so that developmental disturbances occur in the skeletal system (various bony defects), the nervous system (hyperactive deep tendon reflexes, paralysis of the vocal cord,[14] gliosis of the cortex),[6] the eye (strabismus, nystagmus),[5] the urinary system (absent kidney), the genitalia (testicular hypoplasia, transposition of the external genitalia)[12] and the hematopoietic system (hypoplasia or aplasia of the bone marrow). Disturbances in bone marrow, therefore, are merely part of an array of multiple congenital defects.

This syndrome appears to be more common in males than in females. Most instances of Fanconi's syndrome show a familial incidence, although as already noted, sporadic cases also have been reported, including our two patients. Sporadic instances may be due to spontaneous mutation of genes. Each of our patients was an only child, and the absence of siblings leaves open to question whether the syndrome will repeat itself in these families.

The congenital abnormalities occurring in this syndrome are protein. Dawson[15] summarized the various anomalies associated with this syndrome in 30 cases. Among these abnormalities, the commonest finding is patchy brown pigmentation of the skin; Fanconi ascribed this to deposition of melanin, and this finding has been confirmed by others.[11,13]

Of course, no definite measurement could be made of our first patient's mental status, but the circumference of her head was much smaller than normal, as was her stature. Our second patient also had extremely small head circumference and stature.

To the best of our knowledge, Case 1 represents one of the youngest patients in whom a definitive diagnosis of this syndrome has been established. The hematologic findings in this patient included severe anemia with thrombocytopenia. The leukocyte counts were increased, perhaps in response to hemorrhage. It is difficult to reconcile the reticulocytosis noted in this patient with the almost complete absence of normoblasts in the bone marrow, although the presence of reticulocytosis in certain cases of hypoplastic anemia, particularly those of congenital type, has been noted.[16]

The hematologic derangement in Case 2 was confined to the erythrocytes, with erythropoiesis in the marrow being greatly depressed; the myeloid line and the megakaryocytes were normal. Thus, this case combines features of both Fanconi's syndrome and pure erythrocytic aplasia (erythrogenesis imperfecta).

Although three of the original patients of Fanconi and several other patients had macrocytic anemia, this is not a constant feature. The anemia is usually normocytic or slightly macrocytic. The bone marrow in this syndrome is described variously as fatty, hypocellular, normally cellular and even hypercellular.

The cause of Fanconi's syndrome is not well known. It is certainly not related to pernicious anemia, as Fanconi originally suggested. Various etiologic factors have been postulated, such as maternal illness during the first trimester of pregnancy,[17] a disturbance of tryptophan metabolism[18] with its by-product of anthranilic acid, and a deficiency of peroxidase in the nuclei of erythroblasts.[19]

This disease is usually fatal. The course of the disease is marked by severe bleeding or progressive anemia or both. Death usually results from hemorrhage into the brain or gastrointestinal tract.

The treatment of patients who have Fanconi's syndrome has been mainly supportive. Periodic blood transfusions may help temporarily; however, if the bone marrow is severely hypoplastic, therapy is usually ineffective. Information concerning the use of ACTH and adrenocortical steroids in this disease is scanty. Remarkable results have not occurred,[11] including the experience with our first patient. Since the original report by Davis and Shumway,[20] transplantation of bone marrow has become increasingly promising. This technique may have future application in the treatment of patients who have Fanconi's syndrome.

Summary

Two cases of Fanconi's syndrome studied at the Mayo Clinic are reviewed. In the first case, pronounced hypoplasia of the marrow normoblasts and megakaryocytes was noted. The diagnosis was established when the patient was six weeks old. In the second case, severe hypoplasia of the marrow normoblasts was the main hematologic abnormality. The second case combined features of both Fanconi's syndrome and pure erythrocytic aplasia (erythrogenesis imperfecta).

Acknowledgment

We wish to express our gratitude to our colleague, Dr. E. C. Burke, who made the second case available to us.

Avian Tuberculosis

ALFRED G. KARLSON, D.V.M., Ph.D.
Rochester, Minnesota

From the Section of Bacteriology, Mayo Clinic and Mayo Foundation, a part of the Graduate School of the University of Minnesota, Rochester, Minnesota.

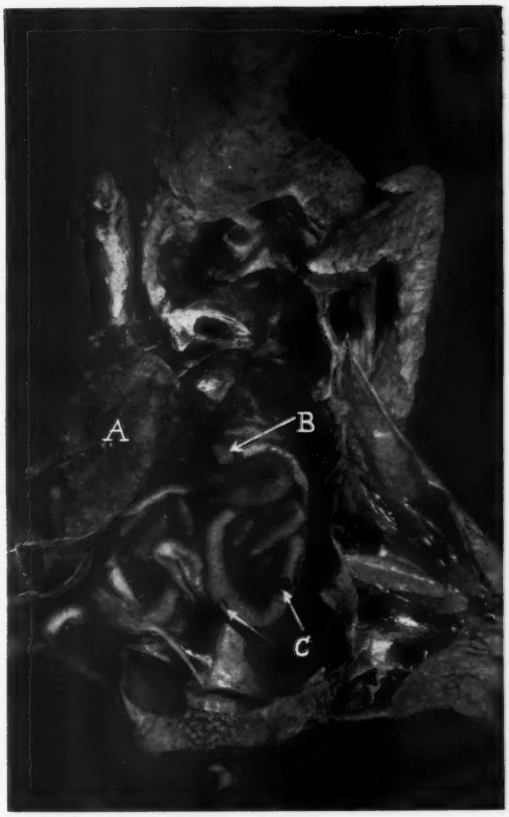

Fig. 1. Tuberculous lesions in the internal organs of a chicken from a farm flock. This bird had reacted to the tuberculin test. There are multiple lesions in the liver (A) and a large one in the spleen (B). Both organs are enlarged. Tuberculous nodules are seen on the intestine (C). (Courtesy of Dr. W. H. Feldman.)

ACID-FAST bacilli that cause tuberculosis in various species may be grouped into three categories depending on their primary hosts: (1) mammalian tubercle bacilli; (2) so-called cold-blooded tubercle bacilli, the cause of tuberculosis in reptiles and fish only; (3) avian tubercle bacilli. Of the mammalian group, the vole bacillus, *Mycobacterium microti,* causes tuberculosis in rodents only. The bovine type, *Myco. bovis,* and the human type, *Myco. tuberculosis,* may infect a number of wild and domestic animals. Except for infection in parrots due to human tubercle bacilli, the mammalian types are restricted to animals.

The avian tubercle bacillus, *Myco. avium,* is of particular interest because it is capable of causing disease in a variety of animals as well as being the principal cause of tuberculosis in avian species. Table I lists a number of common domestic and wild animals and birds that are known to be susceptible to infection with avian tubercle bacilli. In addition to those listed, avian tuberculosis has been found in many kinds of exotic birds in zoological gardens. Avian tubercle bacilli have been isolated from marsupials and from deer. Although a few cases of infection with avian tubercle bacilli have been found in man, the rarity suggests that man is relatively nonsusceptible.

Incidence of Tuberculosis in Chickens

Infection with *Myco. avium* in chickens is common in many parts of the world. In the United States, the extent of tuberculosis in poultry varies. It is almost negligible in the Southeastern states but is quite prevalent in the rural areas of the north central states. In farm flocks of old hens, that is, two years old and older, the infection rate may be 10 to 25 per cent.[2] Most of the tuberculosis in swine in this country is of avian origin. There is a greater incidence of tuberculosis in swine in the north central states than elsewhere in the United States.[3]

TABLE I. PATHOGENICITY OF AVIAN TUBERCLE BACILLI FOR VARIOUS SPECIES*

Birds	Susceptibility	Animals	Susceptibility
Chicken	Marked	Rabbit	Marked
Pheasant	Marked	Swine	Moderate
Turkey	Marked	Mink	Moderate
Parrot	Moderate	Sheep	Moderate
Duck	Moderate	Cow	Slight
Goose	Moderate	Mouse	Slight
Pigeon	Moderate	Rat	Slight
Crow	Moderate	Guinea pig	Slight
Sparrow	Moderate	Dog	Not susceptible
Canary	Moderate	Cat	Not susceptible

*Taken in part from Feldman.[1]

Morphologic and Cultural Characteristics of Mycobacterium avium

Avian tubercle bacilli cannot be distinguished from other acid-fast bacteria on the basis of morphology. The bacilli are slender rods measuring up to 3 microns in length. They may be beaded and slightly curved. They fail to form cords in liquid medium. They grow well at 37° C. on the various media used for tubercle bacilli. Growth appears in one to two weeks. Single colonies are round, elevated, smooth and moist. The growth has a slightly buff tinge of color which becomes more pronounced with age. The smooth glistening growth of avian tubercle bacilli is in contrast to the dry crumbly growth of human or bovine types. Avian tubercle bacilli are relatively resistant *in vitro* to isoniazid, para-aminosalicylic acid and streptomycin. They do not form niacin.

Identification of Mycobacterium avium

The morphologic and cultural characteristics of avian tubercle bacilli are not sufficient for identification. At present it is not known whether these bacilli have any characteristic metaboiic processes that are detectable by *in vitro* procedures. The differentiation from other acid-fast microorganisms must be based on the ability to cause fatal or extensive disease in chickens and rabbits and on the failure to produce progressive disease in guinea pigs. For this purpose, rabbits and chickens are infected intravenously with approximately 0.01 mg. of microorganisms suspended in 1.0 ml. of sterile water, and guinea pigs are given a similar amount subcutaneously. Chickens to be used for pathogenicity tests must be obtained from a source known to be free from avian tuberculosis. The chickens and rabbits must have been tested with avian tuberculin and have reacted negatively prior to infection.

Avian tubercle bacilli in an amount of 0.01 mg. will cause death of the rabbits and chickens usually in three to five weeks. If the animals survive for ninety days, they are killed and examined. The lesions are those of an acute process, particularly enlargement of the spleen and liver. Smears of these organs have innumerable acid-fast microorganisms. In addition to enlargement and infarction of the spleen and liver, the rabbits may have multiple tubercles on the peritoneum. In the chickens, the internal organs are extensively involved with multiple tubercles on the mesentery and in the femoral marrow. Guinea pigs have no involvement of the internal organs but there may be a persistent abscess at the site of injection. Table II shows the relative virulence of avian, human and bovine tubercle bacilli for rabbits, guinea pigs and chickens.

TABLE II. DIFFERENTIATION OF TUBERCLE BACILLI BASED ON RELATIVE PATHOGENICITY FOR LABORATORY ANIMALS

Strain	Pathogenicity		
	Rabbit	Guinea Pig	Chicken
Avian	++++	0	++++
Human	+	+++	0
Bovine	+++	++++	0

++++=Extensive involvement of internal organs; +++=moderate involvement; +=slight involvement; and 0=no involvement.

Lesions of Avian Tuberculosis in Chickens

The naturally occurring infection is usually alimentary in origin. Lesions are most frequently observed in the liver, spleen and intestinal tract although any organ may become involved (Fig. 1). Grossly, there are varying numbers of grayish nodules which range in size from pinpoint foci to irregular masses several centimeters in diameter. Caseation is common. Stained smears of the lesions reveal innumerable acid-fast bacilli. The histopathologic picture is that of a granulomatous process with central necrosis surrounded by a zone of epithelioid cells and giant cells. The lesions vary in extent from single foci to conglomerate processes with extensive caseation. Calcification is rare. Many acid-fast bacilli are seen in appropriately stained sections.

Tuberculin Test

For routine testing of chickens, avian tuberculin is injected intradermally in the wattle. A positive reaction is seen in forty-eight hours as an edematous enlargement of the wattle (Fig. 2). There

is some cross reaction between avian and mammalian tuberculins, which is an important consideration when testing animals that may be infected with bovine, human or avian tubercle bacilli. In swine, for example, it has been recommended that two simultaneous tuberculin tests be made using avian and mammalian tuberculin. Comparison of the severity of reaction may indicate the type of infection since there is usually a greater response to the homologous tuberculin.[3] Cattle infected with avian tubercle bacilli may react to the routine tuberculin test in which mammalian tuberculin is used. Another instance of cross reaction is the sensitization to avian tuberculin that develops in cattle with Johne's disease, which is caused by *Myco. paratuberculosis*. Practical use of this fact is made in the diagnosis of Johne's disease by employing avian tuberculin instead of the homologous product, johnin.

Fig. 2. Positive tuberculin reaction. This chicken was injected intramuscularly with 0.1 mg. of avian tubercle bacilli three weeks before the test. Approximately 0.1 ml. of avian tuberculin was injected intradermally in the right wattle and a similar amount of mammalian tuberculin, 1:100 dilution of old tuberculin, was given in the left wattle. The photograph, made forty-eight hours after injection of tuberculin, shows marked swelling of the right wattle in contrast to the left wattle which was only slightly edematous.

In man, a number of studies have been made in tuberculous patients to compare sensitivity to avian and mammalian tuberculin. An example is a study of 100 patients with pulmonary tuberculosis in which different dilutions of both tuberculins were used. With dilutions of 1:10,000 of old tuberculin (O.T.), 87 per cent reacted to the mammalian tuberculin and only 11 per cent reacted to the avian. However, when dilutions of 1:100 of O.T. were used, the mammalian tuberculin elicited reaction in 97 per cent and the avian in 93 per cent.[4] In a study in India,[5] about 3000 persons were tested with mammalian and avian tuberculin in amounts of 1, 10 and 100 tuberculin units (T.U.). If the area of the reaction did not exceed 6 mm. in diameter, the next higher dose was used. It was found that more than half of those reacting to 1 T.U. of mammalian failed to react to 1 T.U. of avian tuberculin. However, a high proportion of individuals reacting only to 100 T.U. of mammalian also reacted to 10 or more T.U. of avian tuberculin. Only a few reactors to 100 T.U. of avian gave any reaction to lower doses of mammalian tuberculin. The results were interpreted as suggesting two different sensitizing agents, one of which was the human tubercle bacillus which gave the greatest sensitivity to homologous tuberculin at lower doses, and the other of which caused sensitization to both tuberculins only at the higher amounts. Whether or not this agent was an avian tubercle bacillus was not determined. However, it was considered quite likely that the reactions to only 100 T.U. of mammalian tuberculin were actually cross reactions with the same agent that caused the sensitivity to avian tuberculin. Similar results have been obtained in America[6] and in South Africa[7] with avian and mammalian tuberculins. Several reviews of the literature lead to the conclusion that in man a positive reaction to avian tuberculin does not necessarily indicate infection with avian tubercle bacilli.[1,8]

Avian Tuberculosis in Man

It is apparent that man has a high resistance to infection with *Myco. avium*. The widespread distribution of tuberculosis in chickens, and the common occurrence of avian tuberculosis in swine, provide ample opportunity for transmission of the disease to man. However, there are few adequate records of the microorganism's having been isolated from human patients. In a review published in 1953,[8] only 39 cases were recorded in which the diagnosis of avian tuberculosis was acceptable.

In the United States there are four cases in which *Myco. avium* has been isolated by culture and identified by animal-pathogenicity studies. In

each instance, the acid-fast bacilli were given special interest because on original isolation they did not resemble either human or bovine tubercle bacilli. Instead, the colonies were smooth, rounded and slightly buff-colored, which is typical of avian tubercle bacilli. They were identified by demonstrating that the cultures in question were capable of producing progressive tuberculous disease in rabbits and chickens but not in guinea pigs. Briefly, these four cases are as follows.

Report of Cases

*Case 1**.—A 22-month-old child with diffuse infiltration of the right upper pulmonary lobe had acid-fast microorganisms in bronchial washings. One culture of gastric washings developed colonies that proved to be those of avian tubercle bacilli. The patient had a more pronounced reaction to avian than to mammalian tuberculin. She remained free of symptoms during nine months of hospital care, with gradual clearing of the infiltrate. The child had lived on a farm in Minnesota where 50 per cent of 400 chickens were found to react to avian tuberculin.

*Case 2***.—A 59-year-old man with cor pulmonale had a history compatible with silicosis. He had been a tool grinder in a rural town in Ohio. Roentgenograms revealed extensive bilateral pulmonary fibrosis. Acid-fast bacilli in pure culture identified as avian tubercle bacilli were isolated from three cultures of sputum and one of gastric washings. Sections of lung had fibrosis with birefringent crystals. One area of fibrosis had a small focus of necrosis with acid-fast bacilli.

Case 3†.—A 64-year-old granite worker, a lifelong resident of Minnesota, gave a history of exposure to silica and also had roentgenographic evidence of pulmonary fibrosis resembling silicosis. Repeated cultures of gastric washings had colonies identified as avian tubercle bacilli. This patient had a pronounced reaction to avian as well as to mammalian tuberculin. His serum agglutinated antigens from his own culture as well as from cultures of other avian tubercle bacilli.

Case 4.—A 57-year-old farm woman from Iowa had a fluctuating swelling of the right index finger from which tissue was excised. A pathologic diagnosis of tuberculous tenosynovitis was made. Avian tubercle bacilli were isolated by direct culture of the granulomatous tissue. Guinea pigs inoculated with a suspension of tissue failed to have any grossly visible lesions in eight weeks. Treatment with isoniazid and para-aminosalicylic acid was given for eight weeks but was discontinued when the acid-fast bacilli were found to be of avian origin. She recovered uneventfully and function of the hand returned.

*Reported previously.[9]
**Reported previously.[10]
†Reported previously.[11]

It is of interest that the patients in Case 2 and 3 undoubtedly had silicosis. It is well known that certain relatively avirulent strains of acid-fast bacteria such as BCG and H37Ra can produce progressive tuberculous disease in silicotic guinea pigs.

Infection in man with avian tubercle bacilli may be more common than is suspected. Failure to disclose such infection may be due to the common use of guinea pigs for isolation of tubercle bacilli. The relative resistance of guinea pigs to avian tubercle bacilli precludes successful recovery of the microorganism. Another factor may be failure on the part of laboratory workers to recognize colonies of acid-fast bacilli that may be *Myco. avium*. The smooth moist appearance of cultures of avian tubercle bacilli is not typical of the human tubercle bacillus. Such cultures may be discarded as so-called saprophytes without additional studies. The use of rabbits and chickens in addition to guinea pigs for primary isolation, plus animal-pathogenicity tests on all cultures of acid-fast bacilli isolated in clinical laboratories, may disclose more instances of infection with avian tubercle bacilli than are now thought to exist.

Psychiatric Services to Courts

FLOYD K. GARETZ, M.D., and
MARKHAM MATTENSON, B.S.L.
Minneapolis, Minnesota

Dr. Garetz is a Senior Fellow in Psychiatry, Minneapolis Veterans Administration Hospital, Minneapolis, Minnesota, and has served as assistant to the Psychiatric Consultant to the St. Paul Municipal Court.

Mr. Mattenson is a Senior law student, University of Minnesota Law School, Minneapolis, Minnesota.

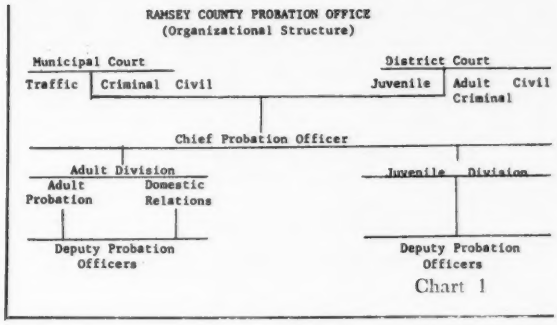

Chart 1

THIS PAPER is an outgrowth of the interest stimulated by the "Combined Law-Medicine Seminar" conducted at the University of Minnesota during the winter quarter of 1959. The seminar had as its goal the improvement of understanding and communications between the legal and medical professions. This paper, in a like manner, has as its aim the improvement of interprofessional understanding.

The specific focus of this paper is the juncture of law and medicine on the common ground of the study of the criminal offender. The paper will first deal with the existing court and probation services offered the courts of Hennepin and Ramsey Counties. It will then offer a prospectus for expansion and improvement of the existing court services.

Court Services Offered in Hennepin and Ramsey Counties

The two major services in this area will be described, compared and contrasted. In Ramsey County, the judicial organization follows the general model seen through the state. The district court bench has jurisdiction over felons of all ages, the majority of civil litigation and of juveniles, no matter what their offense. The St. Paul Municipal Court has jurisdiction over misdemeanors and minor civil litigation.

An important arm of the courts in Ramsey County is the Ramsey County Probation Office. This agency serves all of the courts in Ramsey County. The major functions of the probation office are: (1) doing the pre-sentence evaluation for the court; (2) supervising offenders placed on probation, (3) counseling in domestic relations. The organizational structure of the Ramsey County Probation Office is shown in Chart 1.

The major advantage of the organizational structure of the Ramsey County Probation Office is its ability to provide a unified service to all of the courts in the Ramsey County Area.

Psychiatric consultation to the Ramsey County Courts and Probation Office is in the form of a private psychiatrist who spends one half-day a week at the probation office. Offenders are referred to the psychiatrist by deputy probation officers or directly by the court. There are no specific services of a psychologist to the court at the present time. Offenders are all given M.M.P.I. (Minnesota Multiphasic Personality Inventory) at the time of referral to the psychiatrist. The M.M.P.I. profiles are at the disposal of the consulting psychiatrist, and are used to help evaluate the referred individuals.

The Hennepin County Department of Court Services is Hennepin County's counterpart of the Ramsey County Probation Office. It shows a slightly different organizational structure. In Hennepin County there is a separation between services to the District Court and to the Municipal Court. The Municipal Court has no specific psychiatric services but has at times made use of the facilities provided by the District Court. The court service agency for Hennepin County District Court has

the organizational structure shown in Chart 2.

It is apparent from Chart 2 that the Hennepin County Department of Court Services is organized on a broader plane than is the Ramsey

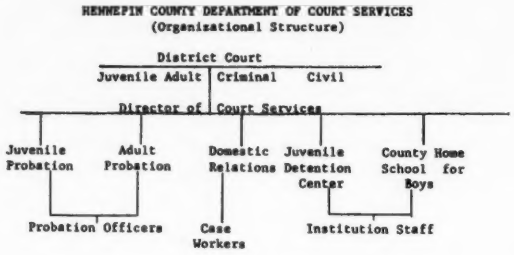

Chart 2

County Probation Office. Hennepin County includes institutional management in its court service agency as well as various probation and counseling services, whereas Ramsey County provides only probation and counseling services. On the other hand, Ramsey County has the advantage of a unified agency for all of the courts, whereas Hennepin County has not succeeded in effecting this kind of unification.

As to specific psychiatric and psychological services, Hennepin County has an arrangement which in some ways is similar to Ramsey County and in other ways different. The clinical staff, so called, of the Hennepin County Department of Court Services includes two full time psychologists and one psychiatrist who spends one-half day a week as court consultant. The usual route of referrals to the clinical staff is from the deputy probation officers, the domestic relations case workers and the staff of the juvenile detention center through their supervisors to the full time psychologists. The staff psychologist performs an evaluation which routinely includes an interview, some kind of personality test and most often a test of intelligence. The psychologist may extend his evaluation to include tests for brain damage and more complete personality testing with the Rorschach (ink blot test) and the T.A.T. (Thematic Apperception Test). There is a slight difference when the person referred is a juvenile. In this group a larger proportion of the total number of offenders who appear in court are referred for psychological testing, and the types of tests are fitted to the age of the offender. If, when he is finished with his evaluation, the psychologist believes that there is need for further consultation, he will refer the case to the psychiatrist.

One of the main differences between the Hennepin County and the Ramsey County psychiatric services is the nature of the offender who is being studied. In Ramsey County, the psychiatrist is consultant to a Municipal Court. This means that the offenders he sees have been accused of misdemeanors and further, he sees only adults. In Hennepin County, on the other hand, the psychiatric service is to the District Court; this means that the consultant sees people accused of felonies, and further, he sees both adults and children.

We turn next to a more detailed description of the function of the psychiatrist as consultant to the court. In one sense, the ultimate aim of the consultants in both Ramsey and Hennepin County is to help the court make wiser and more informed decisions as to the disposition and management of the people who come before the court. The differences between Hennepin County and Ramsey County are primarily in the specific manner of referral and the type of individual seen. The types of problems presented to the psychiatrist and the types of questions he is asked do not differ significantly between the two counties. For this reason, the authors felt justified in drawing primarily in this section from the first hand experience of one of them (Dr. Garetz).

A further elaboration of the psychiatrist's role as consultant to the court may be accomplished by considering the subject in two ways (1) A consideration of the function of the psychiatrist in terms of when, in the temporal sequence of events, the consultation may occur; (2) a consideration of the specific kinds of questions and problems which may be put to the psychiatric consultant.

Chart 3 depicts the sequence of events that occurs when an individual comes to the attention of the court.

The psychiatrist is most frequently asked to act as consultant during the pre-sentence period. At this time the individual has been convicted and the case has been referred to the court service agency for further evaluation to help determine disposition. A member of the staff (deputy probation officer) does a thorough study of the offender's social history, including family history, work record and record of previous court appearances. If, after having made such a study, the staff member feels that psychiatric consultation will be of benefit, a referral is made. The psychiatrist may see the individual in person or he may review all the records with the staff member without actually

seeing the offender. The psychiatrist then writes a report to the court which includes an evaluation of the person's psychiatric status and whatever specific recommendations are appropriate.

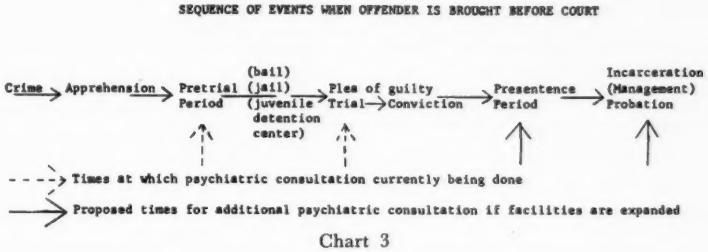

Chart 3

Psychiatric consultation is also frequently requested during the period designated as "management" in Chart 3. The offender (in the criminal cases) or the client (in the case of domestic relation case work) has at some time in the past been assigned by the court to Probation or to Domestic Relations. The staff member responsible for carrying out the probation supervision or domestic case work may ask for specific help in the management of the individual. In addition, referral may be made prior to the release of an individual from incarceration. In this latter case, the offender has already served all or part of a jail sentence and the psychiatrist is asked to see him for help in answering certain questions about the release of the offender.

Occasionally, the psychiatric consultant is asked to see an offender during the pre-trial period to determine whether or not the person is mentally capable of understanding the charge against him, or whether he is able to conduct an adequate defense.

The psychiatrist may also be consulted during the trial. Here he might be asked to testify as to the legal sanity of the offender who has entered a plea of innocence for reasons of insanity. At the present time the consultants to the Hennepin County and Ramsey County court services do not function in this manner.

The second approach to a description of the psychiatrist's function is in terms of the kinds of questions and problems presented to him. First, however, it is necessary to clarify some definitions and state some basic ideas.

Most psychiatrists agree that any individual who commits a serious anti-social act is ill. He is certainly ill in a social sense and is probably to be considered psychiatrically ill if the term is used in its broadest sense. However, the term "psychiatrically ill" is more often used in a restricted sense to mean illness for which psychiatrists have a specific diagnostic label. For example, an individual who commits pre-meditated murder may be considered ill in the broad sense even though a psychiatrist who examines him does not give him a psychiatric diagnosis. For this same person to be considered psychiatrically ill in the narrow sense, he would have to be describable in terms of some specific diagnostic category.

This brings us to another point which needs clarification. Reference will be made in the next section to several major categories of psychiatric diagnoses. The following definitions, although by no means exact or complete, will be adequate for our purposes. *Character and personality disorders* refer to people whose illness has become a way of life and is an integral part of their personality structure. These people are more likely to *act* in an abnormal way than to think or feel in an abnormal way. One important subgroup of the character disorders is the sociopath, an individual whose predominant problem is acting in an anti-social or dysocial manner. *Psychotic diagnoses* refer to people in whom the main characteristic is a loss of contact with reality. *Neurotic diagnoses* refer to people who have certain specific symptoms or combinations of symptoms (such as anxiety, phobias, compulsions, etc.). *Chronic brain syndromes* refer to people who show impaired intellectual functioning as a result of disease process or injury sustained during life. Mental retardation refers to impairment of intellectual functioning present from birth.

With the above definitions as background, the following figures are presented to show the distribution of diagnostic types seen in 100 individuals referred to the psychiatic consultant of the St. Paul Municipal Court. Twenty-five per cent were diagnosed sociopaths; 50 per cent were diagnosed character disorders other than sociopath; 25 per

cent were given various other diagnoses. Of this last 25 per cent, one-half were psychotic, one-fourth neurotic and one-fourth chronic brain syndrome or mentally retarded. It must be emphasized that the 100 cases summarized in the data are all people who were referred for psychiatric examination. This represents roughly 3 per cent of the total criminal calendar for Municipal Court. No diagnostic information is available for the 97 per cent who were not referred.

Returning now to the discussion of the kinds of problems and questions asked of the psychiatrist, the following frequently come up:

1. Is the offender a danger to himself or to society? To answer this question the consultant must evaluate the degree of depression, the presence and degree of psychosis, the previous behavior of the individual, and the amount of control the person has over his behavior at the time of the evaluation. If the psychiatrist is impressed with the potential danger of the offender, then he may recommend hospitalization, both for purposes of treatment and for the protection of society, or imprisonment in the case where there is no available psychiatric treatment.

2. A frequent question arising in domestic relations cases is "which spouse should gain custody of the children in a divorce action?" And a similar question is, "should one party in a divorce action be allowed visiting privileges?" The consultant here must evaluate the stability and responsibility of the parents and the likely effect, both positive and negative, on the children, of contact with either of the parents.

3. A large number of questions are asked regarding probation. These arise during the presentence period. The psychiatrist may be asked to evaluate whether or not the offender is a "good probation risk." He may be able to make specific recommendations as to whether probation supervision should be "loose" or "tight"; or he may be able to point out what particular role the probation officer should assume in his supervision with various offenders. He may further help determine some special contingencies of probation as with the alcoholic who must attend A.A. as part of his probation.

4. Certain problems arise during the management period (Chart 3). The psychiatrist may be asked to help determine whether continuation of probation is wise for someone who has not responded to probation supervision. Here he may be able to help the probation officer change his approach to the offender in such a way that the situation will improve; or he may be able to help the probation officer see that probation was perhaps an unwise disposition to begin with and that it should be rescinded.

5. Occasionally the psychiatrist is asked to see an offender who has served part of a jail sentence and determine if the individual is now ready for probation supervision.

The answers to a whole series of questions are an extremely important contribution of the psychiatric consultant. This involves recommendations for specific psychiatric treatment beyond probation supervision. The psychiatrist may recommend that the individual be referred to a psychiatric clinic for psychotherapy, to a social agency for case work counseling, to a hospital for some specific treatment such as electroshock therapy, or to a private physician for evaluation and treatment of some particular physical ailment.

Recommendations for Expansion and Improvement of Existing Psychiatric Services

Before going ahead with recommendations, it is important to point out that both the Ramsey County Probation Office and the Hennepin County Department of Court Services have done a commendable job in providing the psychiatric services that they now have. The whole area of court psychiatry is one which has tended to be neglected in the past both by psychiatrists and by the courts. Current psychiatric consultation to the courts is of high quality and the present services are certainly a step in the right direction.

However, there appear to be a number of definite limitations in the existing services. Certainly the amount of service available is less than what is needed. Cases which should be presented to the psychiatric consultant are probably not presented because of his time limitation. The question arises as to whether or not a full-time psychiatric consultant to the court is a desirable goal. Generally, psychiatrists doing court work feel that it is better to have a psychiatrist consult on a part-time basis. This would mean that to meet the needs of the court for psychiatric consultation, it would be necessary to have the psychiatrist spend more than one-half day a week doing court work or to have several psychiatrists instead of one. The reason usually given for this point of view is that it would

be difficult for the psychiatrist to maintain a high level of interest in his work if all he did was evaluate offenders.

However, this leads to another set of recommendations. It would be possible for a psychiatrist to work full time in such a setting if the organization of the psychiatric services was in the form of a court clinic. By court clinic, we mean a structure in which all of the necessary psychiatric and psychological services to the court would be provided by a more or less self-contained clinic. (An outline of a possible structure for a court clinic is given in Chart 4). The ideas for this model court clinic come from the experience of the authors and from examination of other court services, particularly the court clinic for the Court of Special Sessions in New York City.

The director, a full-time psychiatrist, would coordinate the activities of all other members of the clinical staff. In addition, he would be available to give advice on specific problems and would act as a liaison between the clinical staff and the court.

The psychologist would have several functions. He would perform psychological testings and interpret their results. This could be a routine battery for all individuals referred to the clinic consisting of the M.M.P.I. and the Shipley Hartford (estimate of intelligences). He would do further testing when indicated. The psychologist would also have an important role in research. Research activities would be planned jointly by the director and the psychologists and carried out by all of the clinical staff. The research assistants would do statistical and clerical jobs.

It is worth expanding a little on the topic of research. One of the harsh realities of court work is that it is extremely difficult to modify the antisocial behavior of a large proportion of offenders. Further, crime, delinquency and the like are massive social problems. It seems evident that, as important as it is to provide service to the court, it is equally important to be ever searching for ways of better handling the offender and of preventing people from becoming criminals. Research is necessary to insure progress in this area. The court clinic is an ideal place for such research.

Returning to the staff of the court clinic, we next consider the function of the social worker. This staff member would collect information about the offenders which would help in the evaluation. He would also do case work counselling with certain selected offenders.

One of the functions of the part-time psychiatric consultant would be to supervise the social worker doing case work counselling. Another set of duties would be those currently performed by the psychi-

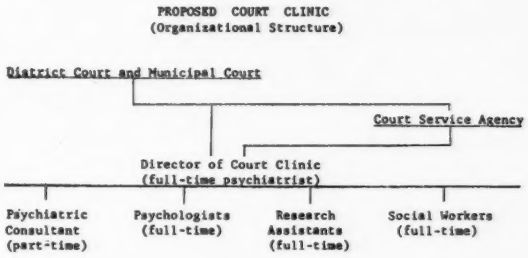

Chart 4

atric consultant. A final important function of the new part-time consultant would be prescribing medications to selected offenders who need such medication as part of their total management by the court clinic.

In addition to all of the activities outlined above, the court clinic could potentially serve the court in two areas which in the current existing court services are being neglected. Namely, evaluations in the pre-trial period and evaluations and testimony during the trial. If this were the case, a long step would be taken to eliminate the battle of the experts on the witness stand.

Such a model court clinic presents many difficulties. The greatest difficulty is in getting funds to support such a clinic. Another equally important problem is getting trained people interested in working in such a setting. However, in spite of the problems, such a clinic is well within realistic aspirations. Both Ramsey County and Hennepin County are moving in the right direction. The ultimate goal of achieving a court clinic that will meet the needs of the community will require the sustained effort and interest of people from both the legal and the medical professions. It is hoped that this paper will play a part in stimulating such interest and effort.

Acknowledgments

The authors wish to express their appreciation to the judges of Hennepin and Ramsey Counties, the Ramsey County Probation Office and the Hennepin County Department of Court Services for help in preparing this paper.

Injuries of the Brain Caused by Penetration of the Orbit (Pitchforks, Sled Runners, Arrows, Etc.)

Among the hazards to which active children are exposed are severe brain injuries caused by low-velocity missiles penetrating the orbit. Five such cases are reported. The prognosis should be guarded, because extensive and permanent incapacity may follow what appears to be a relatively minor injury.

INJURY to intracranial structures inflicted by objects which penetrate transorbitally is unusual in peacetime. Orbital cranial wounds, secondary to high-velocity missiles, are common in time of war, a subject which has been reviewed by several authors.[1,2] In contrast to the injuries from high-velocity wartime missiles, the injuries produced by low-velocity objects present a unique clinical problem.

In the last five years five cases of intracranial injury secondary to transorbital penetration by low-velocity missiles have been recorded at the Mayo Clinic. The occurrence of three such injuries within the last few months prompted us to review the literature on this subject and to present reports of the cases in question.

Anatomic Aspects

The important anatomic features to be considered in this type of injury have been discussed by McClure and Gardner.[3] Some knowledge of the anatomy of the intra-orbital contents and adjacent intracranial structures is necessary to an understanding of the clinical syndromes secondary to this type of injury and to the management of the victims.

The orbital cavities are roughly pyramidal in shape, the base of the pyramid being represented by the orbital rim. The orbit is formed by the frontal, ethmoid and lacrimal processes and the zygomatic portion of the temporal bone and the greater wing of the sphenoid bone. At the apex of the orbit is the optic foramen through which pass the optic nerve and the ophthalmic artery. Lateral to the optic foramen are the superior and inferior orbital fissures. Passing through the superior orbital fissure are the superior and inferior divisions of the oculomotor nerve, the trochlear nerve, the abducens nerve, the nasociliary nerve, the frontal nerve and the ophthalmic vein. The globe of the eye is movable, and is surrounded by fibrofatty tissue, the extra-ocular muscles, nerves and blood vessels.[4]

MATTHEW H. BULLUCK, M.D.
GEORGE S. BAKER, M.D.
JOHN W. HENDERSON, M.D.
Rochester, Minnesota

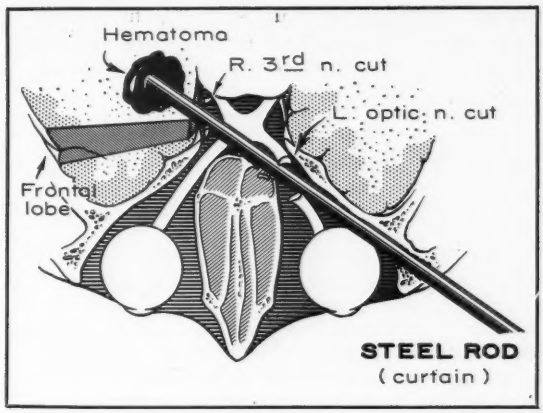

Fig. 1. Course of the foreign body through the orbit in Case 1.

From the Section of Neurologic Surgery and the Section of Ophthalmology, Mayo Clinic and Mayo Foundation, a part of the Graduate School of the University of Minnesota, Rochester, Minnesota.

Rupture of the globe by large blunt objects such as stones, golf balls, tennis balls and the like frequently occurs, but because the globe is movable and may be displaced by low-velocity blunt objects, it often escapes injury. A long, rigid missile will tend to be deflected by the walls of the orbit to the region of the apex, where the nerves and vessels are concentrated. The bony orbit, except for the rim and lateral borders, is thin, and therefore may be penetrated easily at any of the vulnerable points.

Resting on the roof of the orbit is the inferior portion of the frontal lobe of the brain. This anatomic relationship is especially advantageous to the neurologic surgeon in the performance of transorbital prefrontal lobotomy. In the middle cranial fossa, behind the greater wing of the sphenoid process, are the internal carotid artery and its branches, located in close proximity to the cavernous sinus, the pituitary gland and the hypothalamus.

The many complications and the various clinical findings associated with all penetrating wounds about the orbit are understandable when the anatomy of this region is carefully considered.

Review of the Literature

The first comprehensive review of injuries of the type under consideration was made in 1930 by Birch-Hirschfield,[5] who reported on 172 cases of stab wounds of the orbit, including three cases of his own. Of these, 125 cases involved lesions of the optic nerve. Twenty patients died, eleven of meningitis, six from injury to the internal carotid artery, and three from tetanus. McClure and Gardner[3] in 1949 reviewed the literature and presented four cases. These authors were impressed by the fact that the eyeball frequently escapes injury in such incidents. They had the impression that intracranial damage should be expected in all cases of stab wounds about the orbit. Kjer[6] reported on fifteen cases of orbital and transorbital stab wounds. He noted the important fact that three of his nine patients with intracranial injury did not exhibit symptoms of intracranial damage

immediately after the injury. Three of his patients died of causes secondary to the injury. These deaths were the results of tetanus, cerebral edema and encephalitis.

Aside from the above-mentioned reviews, many reports of isolated cases have been published.

Report of Cases

Case 1.—A 7½-year-old girl was admitted to the Mayo Clinic with a history of unconsciousness of three hours' duration which followed injury below the left eye inflicted with a piece of steel about the size of a curtain rod. The child had been injured when a small boy threw a steel rod into a tree in an effort to dislodge his kite. At the time, the patient had been looking up at the kite and had received a penetrating injury in the left maxillary region when the rod fell earthward (Fig. 1). The rod was immediately withdrawn by the patient's mother and the child was taken to a local physician, who referred her to the clinic. The actual depth of penetration was not known.

At admission the patient was comatose. The blood pressure was 118 systolic, and 52 diastolic, in millimeters of mercury; the pulse rate was 96 beats per minute and the temperature was 102.4° F. There was a puncture wound in the left cheek beneath the eye. Both pupils were dilated and fixed, and the left eye was closed by edema and ecchymosis. The optic fundi were normal. Neurologic examination disclosed left hemiplegia; the Babinski response was elicited bilaterally. General physical examination revealed no other abnormalities. Roentgenograms of the skull clearly showed a fracture involving the left antrum. Results of routine laboratory tests were within normal limits.

On the day the patient was admitted, left transfrontal craniotomy and right temporal burr-hole exploration were performed. A marked degree of cerebral edema was noted. The left frontal lobe was resected and damage to the left optic nerve was seen. Fracture of the roof of the orbit was not found. Because of extreme swelling of the brain, the bone flap was left out for purposes of decompression, and tracheotomy was performed postoperatively. Antibiotic agents and prophylaxis against tetanus were employed.

The child remained in coma and showed no evidence of neurologic improvement. Approximately a month after admission she was dismissed to receive nursing care at a hospital near her home. Over a five-month period the patient gradually improved. When she returned for reexamination six months after the injury, she exhibited expressive aphasia and was unable to walk by herself because of left hemiplegia. Examination of the eyes at this time showed divergent strabismus, with almost complete paralysis of the ocular movements. Ptosis of the right lid was seen. The left optic disk was affected by pallor of grade 3 and the right disk exhibited minimal pallor. At this time physiotherapy was instituted and lengthening of the Achilles tendon on the left was performed.

Nine months after the injury the patient was readmitted for repair of the cranial defect secondary to the transfrontal craniotomy. During the operation, a cystic area in the left frontal lobe was encountered. A defect in the wall of the left lateral ventricle was repaired with an ivalon graft. Repair of the cranial defect was delayed because of this lesion. She returned three months later, a year after the original accident, and cranioplasty with acrylic material was done. The postoperative course was uneventful.

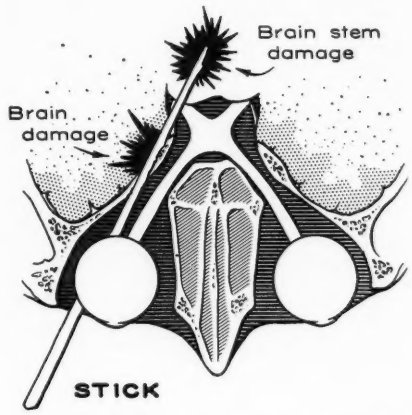

Fig. 2. Course of the foreign body through the orbit in Case 2.

The patient returned six months later for correction of the ptosis of the right lid. When she was last seen three years after the injury, examination of the eyes revealed little movement of the left eye and a fixed right eye with slight ptosis. Examination of the optic fundi showed dilated, fixed pupils. The right optic disk was affected by grade 2 pallor, but the fundus otherwise was normal. Grade 4 pallor was noted in the left optic disk.

When this patient was last heard from, nine months after the foregoing examination, she was able to be up and about and was attending a school for the blind. The aphasia had abated to a point at which she had only slight hesitancy in speech.

Case 2.—A 7-year-old boy was struck beneath the right eye with a stick while playing with friends. He walked to his home and suffered no immediate ill effects from the injury. After arriving home, however, he very rapidly became incoherent and drowsy. He was immediately taken to his family physician who sutured the wound of entry and transferred him to the clinic, after administering antibiotic agents and tetanus toxoid. At the time of admission the child was comatose, and exhibited periods of extreme restlessness.

The blood pressure was 152 systolic and 52 diastolic, in millimeters of mercury; the pulse rate was 80 per minute and the temperature was 105° F. Ecchymotic swelling involved the upper lid of the right eye, and there was a sutured laceration of the inner aspect of the upper lid. This laceration appeared to involve the upper canaliculus of the lacrimal apparatus. The pupils were of equal size and reacted to light. The ophthalmologist felt that there had been no damage to the right globe. Results of neurologic examination otherwise were nega-

tive and roentgenograms of the skull showed no fracture.

Bifrontal craniotomy was performed on the day of the patient's admission. A marked degree of swelling of the brain was noted, and fracture of the roof of the right orbit, with laceration of the dura and brain, was found (Fig. 2). The damaged areas were debrided, and a portion of the right frontal lobe was removed for purposes of decompression.

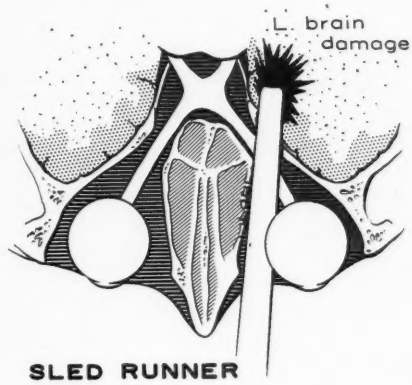

Fig. 3. Course of the foreign body through the orbit in Case 3.

Postoperatively, the patient failed to regain consciousness. The temperature persisted at 105° F. and tremors of the right upper extremity and episodes of decerebrate rigidity developed. On the day after the operation, tracheotomy was performed. The next day the patient died.

Postmortem examination demonstrated purulent meningitis, abscess of the left frontal lobe and empyema of the right orbit.

Case 3.—A 9-year-old boy was transferred to the clinic after hospitalization for 10 days in another city. While he was out sledding with friends, the patient overtook a sled in front of him which for unknown reasons suddenly stopped. A sled runner inflicted an injury to the left eye. The boy was immediately taken to a local hospital, where the wound of entry was debrided and sutured. He received tetanus antitoxin and antibiotic agents. He did not lose consciousness at the time of the injury, and he complained only of neck pain and stiffness. But since irritability, drowsiness and fever developed, he was transferred to the clinic for further study.

He was found to be an alert, irritable boy with marked chemosis and ecchymosis of the soft tissues of the left orbit. The left globe appeared to be intact; the boy said he was able to see with it. The globe was fixed. Examination of the optic fundus on this side was impossible because of extreme corneal edema. The pupil was dilated and fixed. An extreme degree of irritability similarly precluded examination of the visual fields. Neurologic examination at this time showed no deficit, except for a stiff neck and elicitation of Kernig's sign. Results of routine laboratory studies were within normal limits, and roentgenograms of the skull disclosed no evidence of fracture. Roentgenograms of the orbital aspects likewise revealed no definite fracture.

The next day the child became more irritable and hyperactive. Progressive proptosis of the left eyeball was noted, and Babinski's sign was demonstrated on the right side. Electroencephalography performed at this time recorded a grade 1 localization of delta waves in the left sylvian region, associated with grade 2 generalized dysrhythmia. Evidence of increasing cerebral irritation persisted. Two days after admission of the patient left transfrontal craniotomy was performed.

An intracerebral hematoma was evacuated from the left frontal lobe. Debridement of a large penetration through the orbital plate was necessary; there were multiple fractures extending into the ethmoidal sinuses (Fig. 3). The left optic nerve appeared to be intact. The contents of the orbit were explored, but no evidence of increased intra-orbital pressure was found. The periorbita was left open for purposes of decompression.

Postoperatively, the child responded promptly to the intracranial decompression, but on the fourth day diabetes insipidus developed which was controlled by the use of vasopressin (Pitressin). Chemosis and proptosis of the left eye persisted, and for these reasons, two weeks after craniotomy, complete blepharorrhaphy was performed on the left side. General improvement continued and the child was dismissed from the hospital a month after the operation.

The patient was re-examined seven months later, at which time it was noted that the diabetes insipidus had disappeared entirely. The boy was in good condition. He could perceive light in the left eye, but it was thought advisable not to open the eyelid until the orbital bone should have had more time to recalcify.

Case 4.—A 10-year-old boy was admitted to the clinic about three hours after injury to the right orbit inflicted by the tine of a pitchfork. He was not unconscious after the injury, and gross damage had not been noted by his family physician, who referred him to the clinic after administering tetanus toxoid.

The child was found to be awake, alert and co-operative. The blood pressure was 122 systolic and 72 diastolic, in millimeters of mercury; the pulse rate was 88 beats per minute and the temperature was 100° F. per rectum. A general physical examination disclosed no abnormalities. The right eye was ecchymotic and the lids were closed. There was a small slit in the skin at the tip of the lateral canthus and a large conjunctival hemorrhage. Proptosis of 4 to 5 cm. was noted. The globe was fixed. Grade 4 ptosis of the upper lid and iridoplegia also were present. Corneal sensation was diminished. Funduscopic examination of both eyes disclosed no abnormality. Vision in the left eye was normal, and some degree of vision remained in the right eye. Neurologic examination disclosed no abnormalities. Roentgenograms of the skull revealed no fracture, but roentgenograms made in special orbital views demonstrated a fracture medial to the superior orbital fissure. The electroencephalogram recorded dysrhythmia of grade 2, generalized, and maximal in the right anterior cerebrum. A delta-wave focus

of grade 2 was generalized but was maximal on the right.

The administration of antibiotic agents was started and the child was observed. The next day the neck became stiff and Kernig's sign was elicited, but otherwise the child's condition was unchanged. Examination of the eyes three days after admission of the patient showed some abatement of the ptosis, and the child could read to the extent of 14/21 with a +3.00 lens in the right eye. The fundus remained normal. Lumbar puncture done four days after admission of the patient disclosed blood in the cerebrospinal fluid, grade 3, and the initial pressure of the fluid was 43 cm. by water manometer. Culture of specimens of the cerebrospinal fluid gave negative results. Repeated spinal paracentesis failed to reveal evidence of meningitis, but the amount of blood in the cerebrospinal fluid gradually lessened. The boy was dismissed seventeen days after his admission, with no abatement of the ophthalmoplegia.

The patient returned a month after dismissal, complaining of sudden loss of vision in the right eye three days previously. The next day, in the course of a neurologic examination, the patient suddenly clasped his hands to his forehead and was attacked by a generalized seizure. After this he complained of severe headache.

Results of a physical examination at this time were not remarkable. The neurologic examination disclosed nothing abnormal, and examination of the eyes showed that the ocular condition was unchanged (complete ophthalmoplegia, blindness on the right). An electroencephalogram showed delta waves of grade 1 on the right, frontosylvian, and dysrhythmia of grade 2, generalized, and maximal in the right hemisphere. Lumbar puncture showed the initial pressure of the cerebrospinal fluid to be 40 cm. of water and the fluid to be grossly bloody. Culture of a specimen of cerebrospinal fluid gave negative results.

Antibiotic agents were administered. The temperature was 103° F. on the second day after admission and the patient experienced a convulsive seizure involving the left upper extremity during the day. Ventricular studies showed evidence of subdural collection of blood. Right frontal craniotomy was performed and an intracerebral hematoma was evacuated (Fig. 4). A wound tract into the parietal region was debrided. Because of marked edema, the bone flap was left out. The patient rallied slowly postoperatively but remained blind. Gradually the right ophthalmoplegia abated and the patient was dismissed twenty-six days after admission.

The patient then returned home, where he gradually improved and was up and about. One evening at the dinner table he vomited, and severe headache developed. Within a few seconds he became comatose. His parents brought him to the clinic immediately.

At the time he was admitted a bulging, tense decompressive site in the right frontal region was seen; the pupils were dilated and fixed and Babinski's reflex was elicited bilaterally. The general physical examination provided no remarkable information. The patient was immediately taken to the operating room, where the previously made skin flap was reflected with the aid of local anesthesia. A portion of the right frontal lobe was resected; the right lateral ventricle was found to be filled with blood. The blood could be seen through the foramen of Monro, which was enlarged. Clotted and liquid blood was removed from the third ventricle. After evacuation of blood from the ventricular system the

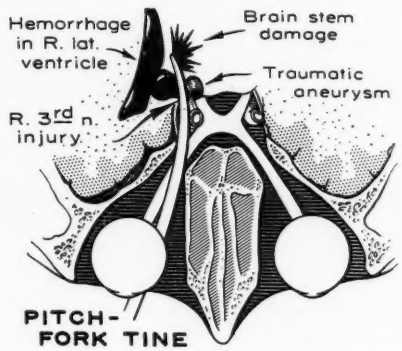

Fig. 4. Course of the foreign body through the orbit in Case 4.

chiasm was inspected. The right optic nerve was small, hard and gray, and was displaced anteriorly by a pulsating blue mass beneath it. This mass was judged to be a post-traumatic aneurysm (Fig. 4), but the condition of the child precluded further definitive treatment at that time. The mass was surrounded by cotton, hemostasis was ensured and the wound was closed without drainage. Tracheotomy was performed immediately postoperatively.

The child did not regain consciousness postoperatively, and six months after the operation was living but had not returned to consciousness.

Case 5.—A 9-year-old boy was admitted to the clinic because of an injury sustained when he had fallen while carrying an arrow in his hand. The point of the arrow struck him near the inner canthus of the right lower eyelid (Fig. 5). He was not unconscious, but left hemiplegia immediately developed. Shortly after the injury he vomited, and his guardians noted that he was very drowsy.

General physical examination of the patient in the hospital produced no significant information. The blood pressure was 110 systolic and 80 diastolic, in millimeters of mercury; the pulse rate was 80 per minute and the rectal temperature was 99° F. Examination of the eyes revealed no injury to the globe, and the extraocular muscles functioned normally. Vision was good. There was some downward displacement of the right globe.

Neurologic examination revealed a drowsy but easily aroused child. Hemiplegia of grade 3 was present on the left, with facial weakness of a central type. Babinski's sign was elicited on that side. Roentgenograms of the skull showed nothing but a fracture through the roof of the right orbit medially, and a minute elevated fragment of the floor of the anterior fossa. Results of routine laboratory examinations were within normal limits.

A prophylactic injection of tetanus toxoid was given

and penicillin and streptomycin were administered. The patient was observed closely at the hospital. Two days after the patient's admission, lumbar puncture yielded xanthochromic cerebrospinal fluid under initial pressure of 30 cm. of water. The fluid contained 5461 erythrocytes and 171 lymphocytes per cubic millimeter, and the

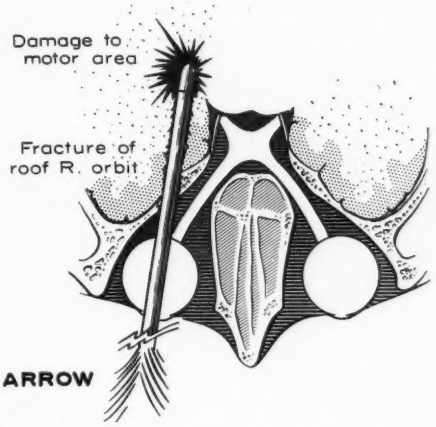

Fig. 5. Course of the foreign body through the orbit in Case 5.

value for protein was 133 mg. per 100 cc. Smears and results of culture were of no significance.

The patient gradually improved, and physiotherapy was instituted. He was dismissed from the hospital three weeks after the injury, and was advised to continue physiotherapy as an outpatient.

This patient was last examined three months after the injury. At that time, he exhibited mild spastic left hemiparesis which required the use of a cane for walking. The patient had returned to school and was doing well otherwise. He made no complaints referable to the right eye.

Comment

It was previously noted that the injuries under consideration were inflicted by missiles of low velocity. It is also apparent, from the data in our reports of cases, that almost all such injuries are secondary to penetration of the bony orbit by long, thin objects. Aside from the objects concerned in this report, some of the instruments responsible for injury in other cases have been broken twigs, a keyhole saw, scythe point, iron bar, fencing foil and ice pick.

The injuries obviously are compound fractures of the skull, and demand that immediate precautions against intracranial or intra-orbital infection and prophylaxis against tetanus infection be carried out. Freeman[7] has reported a series of 628 transorbital leukotomies covering the years from 1946 to 1954, with only seven deaths (1 per cent) attributable to the operation. It is therefore obvious that even though penetrating orbital wounds may be associated with serious intracranial injury, such is not always the case when the injury is perforation of the superior orbital plate.

Summary and Conclusions

Five reports of transorbital injury to the brain have been presented. The salient anatomic and pathologic features of injuries in this area have been demonstrated.

It is obvious that injuries to the brain inflicted by penetration of the orbit constitute a very serious and particularly debilitating problem. Many times a roentgenogram of the skull does not reveal a small fracture through the orbit; when this is true the physician may be misled into a sense of false security because the injury, although present, was not perceived. Nonetheless, in the early phase of any instance of this type of trauma, steps should be taken to ensure the patient against infection. A period of neurologic observation usually is advisable because of the possible sequelae of what appears to be only a minor injury. Sometimes four to six weeks will pass before a prognosis of the visual consequences of such an injury can be given. Any definitive treatment of the visual system had best be deferred until the other, more serious, cerebral complications have been mastered. Very likely, because of the relatively violent physical activity involved in such injuries, most of the victims will be boys. Four of our patients were boys; one was a girl who chanced to be on the scene of somewhat violent, or at least dangerous, activity on the part of boys.

Fractures among Children

II. Some Practical Principles of Treatment of Common Fractures

DONALD S. MILLER, M.D., Ph.D.
Chicago, Illinois

Dr. Miller is Professor and Chairman of the Department of Orthopedics and Traumatology, Chicago, Medical School; Professor of Orthopedics, Cook County Graduate School of Medicine; Chairman, Department of Orthopedics, Mt. Sinai Hospital of Chicago; Attending Orthopedic Surgeon, Cook County Hospital, Chicago, and Oak Park Hospital, Oak Park, Illinois.

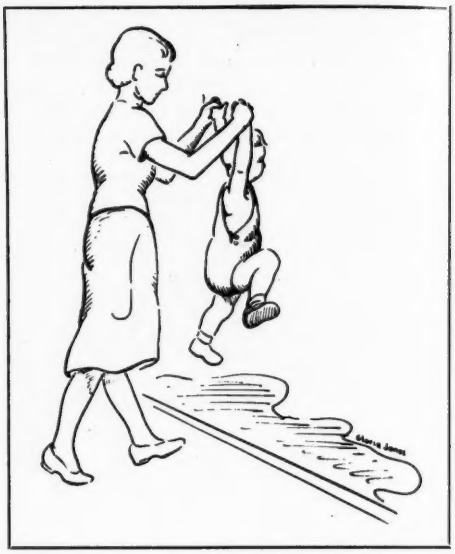

Fig. 10. Usual way in which elbow injuries are incurred. Tear of orbicular ligament or dislocation of head of radius.

Part I, Parental Assault as Causative Agent, appeared in the September issue.

THERE are two categories of fractures among children that are more prevalent than those caused by assault and neglect: (1) the common larger group of simple fractures incurred at play or during the normal activities of childhood and (2) a smaller more serious group of complex fractures from motor accidents.

It is well to be mindful that although reformation of deformities with fractures does occur early in children, nevertheless every precaution is necessary to prevent angulation and rotation of the long bones, especially at the usual sites: the forearm near the wrist, the humerous, the femur, and the tibia. When the fracture is near the joint, epiphyseal injury may be associated. When it is, reduction may be done under general anesthesia provided the stomach is empty even if this means a delay of several hours. Notwithstanding the high degree of self-correction among children through epiphyseal growth, repeated follow-up roentgenographic studies are indicated in order to safeguard against excessive loss of length.

Most fractures of the forearm, including the wrist, are of the simple cortical green stick type or the torus type. They have minimal angulation, are not displaced, and require only simple measures of temporary immobilization. Ace bandaging or an extremely lightweight cast are generally suitable but they must not be tight. Only exceptionally are these fractures seriously displaced, overriding or angulated. Fractures of the upper third of the forearm require more supination of the forearm than do those of the middle third or the lower third which require more pronation. It is necessary to take into account the direction of pull and strain of the muscles in and around the fractured sites in order to follow the correct direction in anatomic positioning.

One of the commonest but most difficult fractures to treat is that of the lower sixth portion of the forearm in which there is dorsal displacement of the distal short fragments. An overriding deformity requires some technical skill in correcting (Figs. 8 and 9). The general plan of treatment is

the application of a well padded forearm cast, preferably extending above the elbow, which is worn for six to eight weeks. The usual way in which injuries to the elbow are incurred is by sudden hyperextension of the upper extremities (Fig. 10). Although the usual supracondylar fracture of the elbow results in good alignment, the occasional one (Fig. 11) may require an osteotomy of the humerus for correction.

Fig. 8. Case of boy, aged seven years. Both bone forearm fracture (lower sixth) treated by hyperextension, proper levering of bone, and application of circular cast.

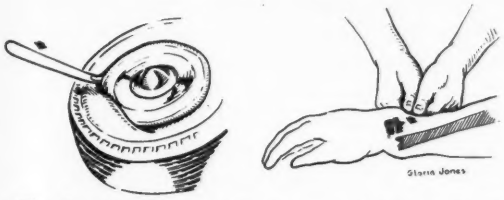

Fig. 9. Method of reducing lower sixth both bone fracture of wrist.

Another type of fracture, less common but more serious and sometimes disastrous, is the Monteggia fracture. This upper sixth portion of the ulna with the head of the radius displaced calls for reduction of the fragments by hyperextension and traction in order to achieve integrity of the elbow joint. Extension of the elbow followed by careful flexion and firm pressure over the head of the radius are essential. The surgeon's thumb acts as a lever to bring the fracture over the fractured site. It is, however, seldom opened for replacement of this

bone. The patient's forearm is pronated before application of a lightweight padded cast.

The secondary scarring, fibrosis, and serious calcification observed in adults do not as a rule happen to children. Pressure must not be increased by tight cases or bandages on the arterial inflow or venous return, for this may bring about neurovascular-muscular complications leading to the dire consequence of Volkmann's ischemic contracture (Fig. 12). The physician must also be watchful for any spicule of bone which can cut into an artery to cause a false dissecting aneurysm or an arteriovenous aneurysm. Casts should be well padded and replaced if necessary in several days. Roentgenographic follow-up studies are indicated to ascertain any displacement.

Fig. 11. Typical supracondylar (elbow a, a_1) fracture, treated conventionally by extension and flexion of the elbow. Osteotomy necessary to correct cubitus varus deformity (b, b_1).

Fractures of the clavicle are treated by immobilization of the involved shoulder for two to six weeks, depending on how severe the fracture is, how much displacement there is, and how much associated soft tissue involvement. For the simple cortical mildly deformed fracture, adhesive tape retention (unless the skin is sensitive to adhesive tape) or a sling is sufficient. Because it is difficult to keep such a bandage on an active child, some children may require lightweight spica casts including both sternoclavicular joints, applied comfortably, with the shoulders immobilized properly. A spica cast seems to serve better than the figure-of-eight bandage. This reduces the swelling and relieves pain. Although pseudo-arthrosis of the clavicle is a cause of mildly painful deformity, it is an uncommon finding. A 20° angulation is an arbitrary gauge for reduction in correcting the fractured site by manipulation with or without general anesthesia.

Fractures of the femur among infants are generally associated with swelling and local hematoma (Fig. 13). When the patient is under three or four years of age, such fractures are best treated by the conventional Bryant's traction, provided extreme care is exercised in the application of the moleskin and bandages, and provided peripheral circulation is scrupulously watched. Both extremities should be carefully padded, and moleskin tape or foam rubber strips applied without constriction. Again, tight Ace bandages are contraindicated. This is worth repetition. Its importance cannot be too forcefully inculcated in the attending physician's mind. The physician, nurse, mother, or whoever is in charge, must watch closely for circulatory changes by observing the color of the extremities. The leg opposite the one injured must be watched just as closely, because sometimes its circulation is affected. When it is, traction must be removed at once. Irreparable harm is likely if these provisions are not met: contractions of the foot, wasting from fibrosis of the calf muscles, scarring of the knee and ankle joints—all are possible but can be prevented by attention to the circulation. Precaution against

soft tissue injury associated with fractures is especially imperative to prevent gangrene (Fig. 14). With normal progress, from four to six weeks' traction may be sufficient. Wearing of a spica cast

Fig. 12. Ischemic fibrosis of both legs, following fracture of the left femur. Treated by Bryant's traction method.

may replace traction unless the callus, as observed roentgenographically, is firm.

For older children, from six to twelve years of age, the conventional traction by a Thomas splint or Russell traction is advisable. The shaft of the femur need not be completely reduced. Side-to-side bone contact is adequate for correction; but rotation and angulation must be prevented. Duration of traction is longer than for younger children and more weight is necessary. The principle of proper alignment to avoid rotation and angulation must be adhered to for the lower extremity as for the upper. Regulation of traction and re-application of bandages or moleskin must be carried through regularly and carefully.

A special group of fractures is represented by compression injuries of the foot (Figs. 15 and 16) and of the hand. Compression states of the tissues may necessitate amputations at Chopart's or Lisfranc's joints. Because of serious hemorrhages in these areas and pressure on the lymphatic vessels, obstruction of lymphatic drainage, local deep scarring and superficial tissue necrosis may ensue. Injuries to the foot are more hazardous than to the hand because of obstruction of circulation and thrombosis in the digital vessels with or without ultimate gangrene of the soft tissues.

Certain assault injuries with associated soft tissue interposition may need plating (Fig. 17). Unfortunately in the case shown in Figure 17, a complication followed: pressure necrosis of the heel from a footboard during traction. Osteomyelitis of the calcaneous is shown in the inllustration (Fig. 18).

Complicated or complex fractures in and about joints are serious; they are incurred mostly during motor accidents and usually require direct surgical approach for correction. Treatment must be skillful. Even so, they frequently result in some degree of joint immobility, shortening or deformity. In addition to the Monteggia fracture already mentioned, isolated condylar fractures in and about the elbow joint or in and about the knee joint require particular attention.

Fractures of the outer condyle through the capitellum require open reduction and fixation with

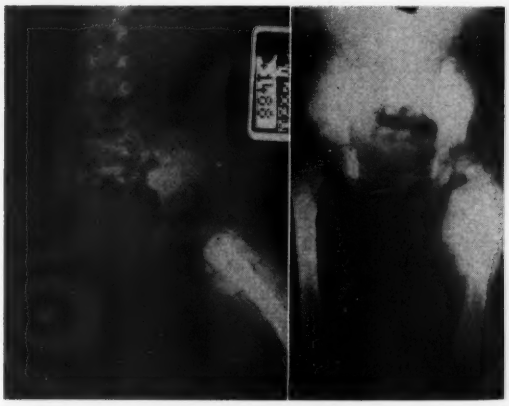

Fig. 13. Fractured femur, shaft and neck. Note calcification, not infrequent from severe hematoma.

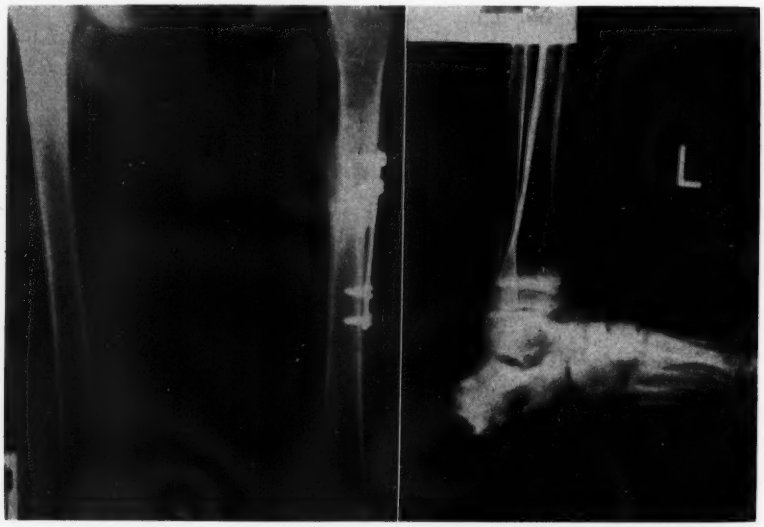
pins or screws (Fig. 19). Closed reduction does not resolve the problem in most of these instances. Hyperextension injuries of the elbow joint, causing displacement of the head of the radius, can be reduced at times under general anesthesia by careful gentle pressure while the arm is extended after first flexing the joint, and by applying pressure throughout this maneuver to the head of the radius.

The most serious injuries are the ones that need immediate attention: fractures through the femoral epiphysis with or without pieces of diaphysis. In such a case pin fixation may be necessary (Figs. 20 and 21). On the other hand, gentle firm traction, manipulation in extension and flexion may reduce the displaced distal short fragment without the necessity of surgical correction. If a

pin or screw is necessary, it should be inserted so as to avoid the growing epiphysis. If not treated properly, serious interference with function of joints and permanent crippling may eventuate



fractures with separation, the rare pelvic fracture with symphysis pubis separation—these are examples of the types of cases among children that probably will require open reduction. Other situ-

(Figs. 22 and 23). If conservative attempts at reduction fail, open reduction must be resorted to as in the elbow case shown in Fig. 24.

ations in which open reduction may have to be resorted to are: when the neck of the femur has been fractured (Figs. 25 and 26); when fragments

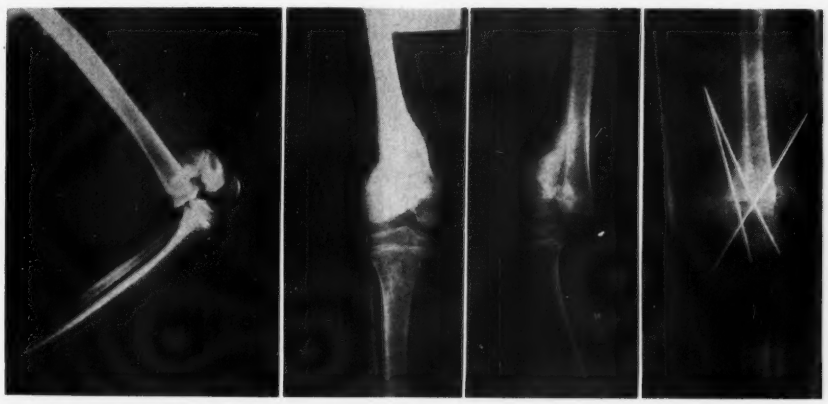
(Turn to Page 1423)

(Continued from Page 1418)

must be reduced in and about the knee joint or for fracture of a single condyle of the femur when the fragments have been displaced (although most fractures of the latter type, including epiphyseal displacements and metaphyseal fractures, can be reduced on the fracture table under steady traction, after which a spica cast must be worn from eight to twelve weeks).

Summary and Conclusions

Fractures among children have been discussed from two points of view: (1) the importance of history-taking in conjunction with taking into account all physical signs of possible violence and neglect in order to establish the etiologic agent, and (2) the application of some working principles of treatment for some of the common fractures and some of the serious fractures incurred at play and especially in motor accidents.



The first part of this presentation is a plea for more widespread and intensive social, as well as medical responsibility for preventing further injuries suggestive of adult assaults in cases that come to the physician's attention. In order to alleviate the situation, the only logical constructive corollary to recognition of the cause of injury, is probing elicitation of the history both to establish the diagnosis and for the social and personal welfare of the child. Significant medical reports touching this subject are briefly incorporated. Four illustrative cases of parental assault are presented—primarily from the sociologic aspect. Two additional illustrations without reports represent parental neglect and assault.

Regarding the second part of this paper, the intention was to present a few practical principles, which are applicable to everyday treatment, not to present an exhaustive technical review of all types of fractures among children.

1. A paramount need to keep in mind is the vascular supply of infants and small children which may be so disturbed in the presence of fracture of a lower extremity as to produce aseptic necrosis and irregularity of growth from epiphyseal arrest. Neglect of compression fractures of the feet may lead to gangrene and even to the necessity for amputation.

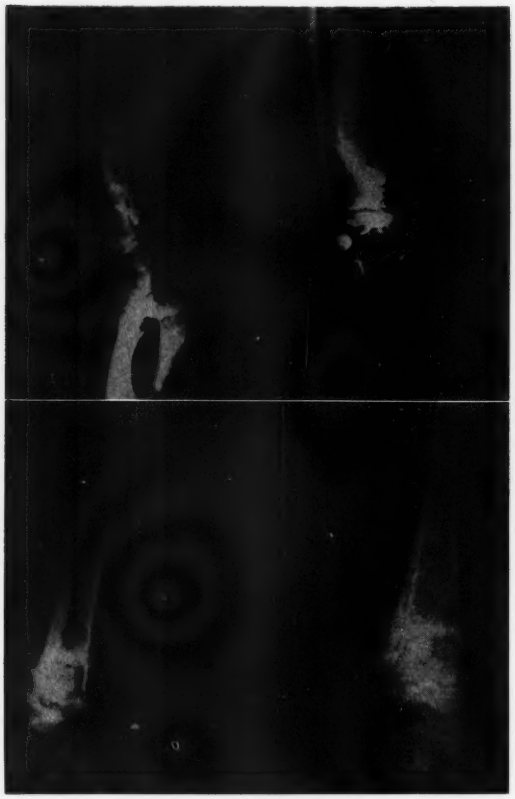


Fig. 19. Fracture of capitellum. Requires open reduction and replacement with screw or pins.

Figs. 20 and 21. Epiphyseal separation with a portion of diaphysis. Closed reduction failed; open reduction with pin fixation necessary.

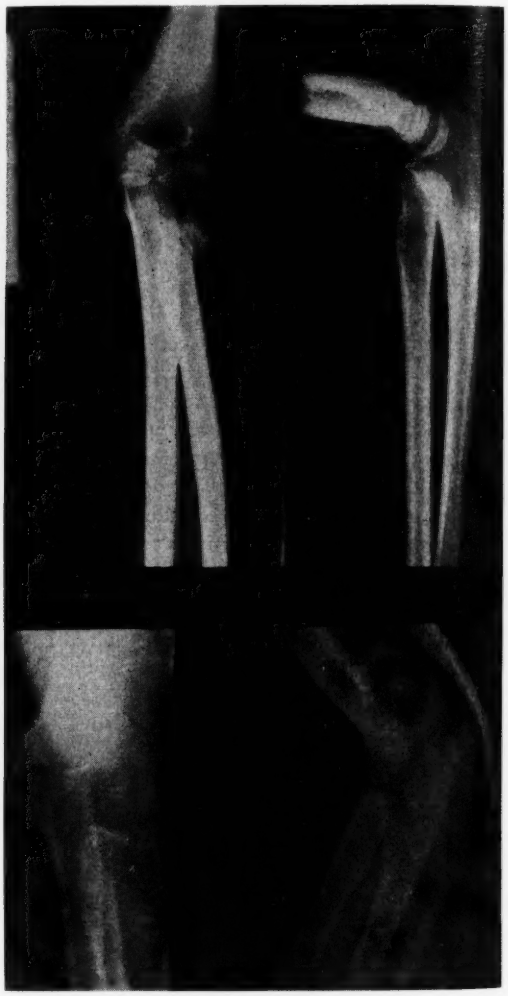
2. Open reduction is performed only under exceptional conditions, such as olecranon fractures with separation; patellar fractures with separation; the rare pelvic fracture with symphysis pubis

Figs. 22 and 23. What not to do: Application of screw plate in a youth, aged fourteen years. Fig. 22 *(above)*. Plate inserted near wrist. Fig. 23 *(below)*. Epiphyseal separation of lower portion of femur. Wiring seen *in situ*. This surgical procedure to be avoided.

separation; when the neck of the femur has been fractured; when fragments must be reduced in and about the knee joint or for fracture of a single condyle of the femur when the fragments have been displaced and cannot be reduced by manipulation or traction. Plating of the child fracture is usually contraindicated.

3. Washing and irrigating for débridement do not mean removing and destroying.

4. In the developing epiphyses of children, given time, after the initial reduction by the physician, self-correction may be anticipated; overmanipulation invites complications. It is the clinical condition of the child and his joint that should be treated, not the roentgenographic appearance of that joint. The roentgenograms are taken to follow the course of angulated or rotated fractures



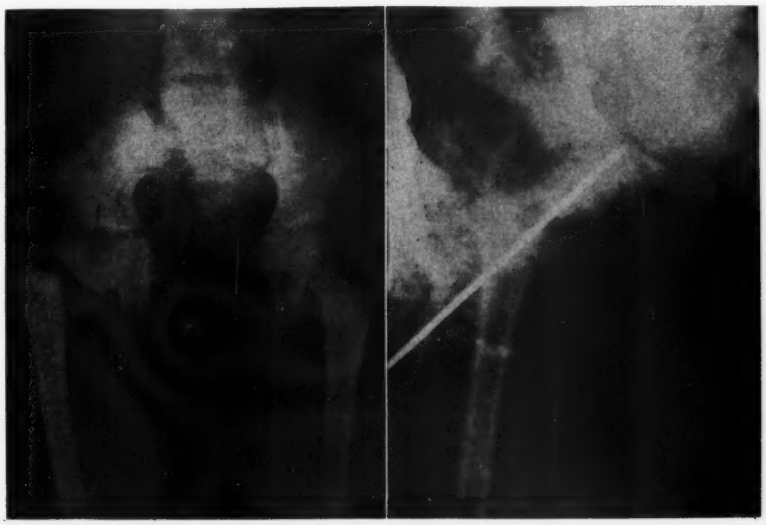


Fig. 24. Fracture dislocation of head of radius. Open reduction necessary to correct displacement of head of radius.

and those fractures that have produced shortening—these must be reduced and may not be left to time and natural repair.

5. The child who is old enough to understand should be told about the fracture and reassured about what is to be done, including reassurance about preoperative medication by injection. By gentle approach, the child will understand the prerequisites and will cooperate.

6. Orthopedic examination is not complete without review and care of the vascular and neurologic systems nor is it complete without painstaking and probing history-taking, particularly in the presence of multiple injuries suggesting parental assault, including bruises and hematomas—besides fractures.

Figs. 25 and 26. Trans-cervical fracture of neck of femur in mongoloid child, aged seven years. Neglect injury (not reported in text). Treated by pin fixation (a_1).

7. Hidden or occult fractures must not be overlooked; they may be disclosed by later rather than by the immediate bilateral roentgenograms. These often substantiate the supposition of parental assault by showing healed fractures in addition to revealing fractures not immediately apparent.

8. Preparation of the emergent patient must not be done in haste to correct the fracture when an anesthetic is necessary. It is far better to delay reduction if the stomach is full; otherwise, regurgitation, lung abscess, sepsis, and death may be consequent.

9. Salient points to remember in the treatment of common fractures are these: (a) avoid rotation and angulation; (b) correct alignment; (c) avoid tight bandages and pressure; (d) be watchful of the circulation; to that end, leave the toes exposed when applying a cast in order to observe the color; (e) be reminded that surgical intervention is not necessary unless the fragments show sequestration by the primary injury or because of the myodynamics; for example, of the olecranon or of the condyles of the elbow or knee.

10. Because orthopedic problems are often emergencies, surely for the welfare of the patient but practically for self-protection against malpractice suits, a thorough and detailed history should be carefully filed in the hospital records.

Diabetic Acidosis

Have you seen a patient in coma lately? This article discusses the recent practical applications of mechanisms concerned in diabetic acidosis which must always be considered in the diagnosis in patients with coma. The significant signs for differential diagnosis and an outline of systematic treatment are conveniently illustrated in the figures.

WITH the advent of improved surgical and medical care, antibiotics and an increasing awareness on the part of both doctor and patient of the need for early treatment of diabetic complications, the number of cases of diabetic acidosis and coma has decreased markedly. When a disease is not seen frequently, the details of its treatment tend to be forgotten. For this reason, it is felt that it will be worthwhile to review the current concepts of the pathologic physiology and therapy of diabetic acidosis and coma.

Diabetic acidosis and coma is a medical emergency of major degree and recovery depends upon its early recognition and aggressive treatment. It is due to a decreased ability of the body to utilize glucose. When the utilization of glucose falls below a certain level, there is an increase in the metabolism of fat. In situations in which the general rate of metabolism is increased, such as pregnancy, infection and surgery, increased metabolism of fat occurs at a higher level of glucose utilization than when the metabolic state is normal. It is, therefore, much easier for diabetic acidosis to occur in those conditions. As a result of the increased fat metabolism, organic acids called ketone or acetone bodies accumulate faster than the body is able to complete their oxidation. In the early stages, the kidneys, and to a lesser extent the lungs, are able to excrete the excess acetone bodies of the blood. Eventually the acetone bodies are produced at a rate which exceeds the body's ability to dispose of them. Diabetic acidosis is, then, a chemical intoxication coupled with secondary effects of water and electrolyte imbalance. Hyperglycuria produces its marked diuretic effect; each gram of glucose lost in the urine carries with it approximately 20 c.c. of water. Large amounts of base are needed to neutralize the acetone bodies being excreted in the urine. The readily available sodium ion and smaller but important amounts of potassium are used by the body for this purpose. As sodium is excreted in the urine, the CO_2 that was combined with it as HCO_3 is freed and excreted by the lungs through increased depth and rapidity of respiration. This ultimately results in lowered plasma CO_2. Large amounts of chloride are lost as salt through the urine in the polyuria that results from the glycosuria. These changes result in the dehydration and electrolyte imbalance that characterizes the acidotic state. If they continue uninterrupted, falling blood pressure, vascular collapse and eventually renal failure occur. Changes in the tubules characteristic of lower nephron nephrosis may occur. Once this pathologic lesion has occurred, treatment with large amounts of fluid is extremely hazardous.

TABLE I. DIAGNOSIS

Plasma Co_2	Stage	Symptoms & Signs	Recognition
23 mEq.	Mild acidosis	Vary from NONE to; polyuria, polydypsia, acetone breath. Increased glycosuria and ketonuria.	Test urine for sugar and ketone bodies. Blood sugar and CO_2 changes.
15 mEq.	Severe	Lack of appetite, nausea, vomiting, abd. pain.	Symptoms plus laboratory findings.
9 mEq.		—DYSPNEA—	
4 mEq.	Pre-coma to coma	Kussmaul breathing; stupor Circulatory collapse; death	Symptoms plus laboratory findings.

HERBERT W. JOHNSON, M.D.
Saint Paul, Minnesota

Symptoms and Signs

It is simplest to divide diabetic acidosis into a mild and a severe stage from the standpoint of both diagnosis and treatment. A significant degree of acidosis may occur without symptoms.

Mild Acidosis—Recognition in this relatively symptom-free stage of acidosis depends largely on testing of the urine for glycosuria and ketone bodies and upon chemical analysis of the blood. There may be mild polyuria and polydypsia coupled with moderate dehydration. The plasma CO_2 is usually above 15 MEq. When recognized as being in this early stage of acidosis, the diabetic can be easily and simply restored to normalcy by simple hydration and regulation of insulin dosage.

Severe Acidosis.—When the plasma CO_2 falls below 13 to 15 MEq., unmistakable signs and symptoms begin to appear. Frequently the stage of severe acidosis is ushered in by digestive disturbances such as anorexia, nausea and vomiting. Pain often accompanies the nausea and vomiting. The pain is most commonly in the abdomen and may be colicky. It is usually accompanied by leukocytosis and low grade fever. A guarded or rigid abdomen may be present and cause confusion in diagnosis with appendicitis, peritonitis, gall bladder or ureteral colic. The pain may originate in or radiate to the chest and when accompanied by Kussmal respiration, appear sufficiently like pneumonia to cause confusion.

Kussmal breathing ushers in the true precoma phase of acidosis. It occurs when the CO_2 reaches a level of about 9 MEq. It is usually followed shortly by drowsiness and, as the CO_2 level of the plasma continues to fall, by coma. Kussmal respiration represents an extreme danger sign and demands aggressive treatment.

As the plasma CO_2 continues to fall and reaches a level of 4 to 5 MEq., general collapse results. Blood pressure falls, a weak thready pulse occurs, respiration becomes more and more shallow, urine output decreases and death occurs.

Differential Diagnosis

The known diabetic receiving insulin who is seen in an unconscious state may present a difficult differentiation between diabetic coma and insulin reaction. The giving of additional insulin to a patient already in hypoglycemia, or the withholding of insulin from a patient in diabetic coma, may lead to a fatal outcome. Diabetic coma comes on gradually over a period of days or hours whereas an insulin reaction is manifest in a much shorter interval. It must be remembered, however, that

reactions due to protamine zinc insulin may be very gradual in onset. The following signs usually

TABLE II. DIFFERENTIAL DIAGNOSIS

	Diabetic Coma	Insulin Reaction
1. Onset	Slow	Sudden
2. Thirst	+	−
3. Hunger	−	+
4. Vomiting	Common	Seldom
5. Pain in abd.	−	+
6. Skin	Dry—florid	Moist—pale
7. Eyeballs	Soft	Normal
8. Respiration	Air—hunger	Normal
9. Glycosuria	+	Absent (check 2nd spec.)
10. Ketone bodies	+	−!

suffice to differentiate between the two.

When faced with the problem of unconsciousness in a diabetic patient under conditions in which laboratory studies are impossible to obtain, one is always justified in giving a small amount of concentrated glucose solution intravenously in order to help rule out an insulin reaction.

The similarity between the acute abdomen and diabetic acidosis has already been mentioned.

A cerebrovascular accident may present a picture similar to diabetic acidosis and create an especially difficult differential diagnosis in a known diabetic. Strong evidence in favor of a vascular accident, either in a diabetic or a non-diabetic, is the presence of neurologic abnormality such as asymmetrical changes in the reflexes, localized muscular weakness or evidence of cranial nerve involvement.

An alcoholic in coma may occasionally present a problem in differential diagnosis and without an adequate history, laboratory studies may be essential in making the diagnosis.

Uremia may be associated with severe dehydration and ketonuria but rarely glycosuria. The CO_2 combining power is frequently reduced, but the blood sugar level is not elevated. Since diabetics in late stages of the disease may develop uremia, the coexistence of the two conditions must be considered.

Treatment

Diabetic acidosis and coma must be considered as an emergency of the first order. A source of infection must be searched for since it is often a precipitating factor. As soon as the diagnosis has been established, large doses of regular (crystalline) insulin should be given. There should be no hesitancy in giving enough insulin to achieve the desired result. In general the initial dose of insulin can be gauged as follows. If the blood sugar is over 600 mgm. per cent, 100 units of regular insulin may be given intravenously and up to an additional 100 units of regular insulin should be given subcutaneously depending upon the severity of the acidosis. If the blood sugar is between 400 and 600 mgm. per cent, 50 to 75 units of regular insulin can be given intravenously and 50 to 75 units subcutaneously. With a blood sugar of 300 to 400 mgm. per cent, 25 units of regular insulin may be given intravenously and 25 to 50 units subcutaneously. Forty units of regular insulin subcutaneously will usually be adequate if the blood sugar is below 300 mgm. per cent provided that severe acidosis is not present. It should be remembered that any given dose of insulin will be less effective in the presence of severe acidosis.

TABLE III. TREATMENT

Fasting Blood Sugar Levels	Initial Insulin Dosage Given as Units of Crystalline (Regular) Insulin
1. Over 600 mgm %	1. 100u. I.V. plus .100u. subq. if patient is in severe acidosis.
2. 400 to 600 mgm %	2. 50 to 75u. I.V. plus 50 to 75u. subq.
3. 300 to 400 mgm %	3. 25u. I.V. plus 25 to 50u. subq.
4. Below 300 mgm %	4. 40u. subq.

In one to two hours re-evaluate the patient and give insulin accordingly. In severe acidosis may need 100 to 200u. every hour.

After administration of the initial insulin and other measures to be mentioned later, the patient must be kept under close observation. Antibiotics should be administered if needed. A diabetic coma sheet showing the blood sugar and other chemistries, insulin given, fluids given, hourly urine sugar tests and urine output should be kept. Much confusion in treatment will be avoided if this is done. Intravenous fluids should be started and a blood sample drawn for determination of CO_2,Cl and urea. A catheter should be inserted and the stomach lavaged if necessary. It is well to get an electrocardiogram for comparison with later tracings since the question of hypopotassemia will arise.

Thereafter, hourly urine sugars should be done and the dosage of insulin adjusted accordingly. Thirty units of regular insulin may be given for a 4 plus sugar, 25 units for 3 plus, 20 units for 2 plus, and 10 units for a 1 plus sugar. Larger doses from 100 to 200 units of regular insulin may be needed per hour in the presence of severe acidosis. The exact dose must, of course, be individualized. Blood sugar, CO_2 and Cl should be

done every three to four hours until the patient is out of danger.

I do not favor the use of any insulin except regular (crystalline) insulin during the first 24 to 48 hours of therapy since insulin with delayed action is too slow to intervene actively in the early treatment and may predispose the patient to severe hypoglycemic reactions during the next twenty-four to thirty-six hours.

Fluid Therapy

The need for proper fluid replacement in the diabetic in acidosis is as great as the need for insulin. It must be remembered that there are several coexistent problems.

Dehydration.—The adult acidotic patient will require between 3000 and 8000 c.c. of fluid in the first twenty-four hours of therapy. The solution should be given as rapidly as the circulatory state of the patient will permit.

Acidosis.—The readily available base of the body has been excreted in the urine in an attempt to neutralize the ketone bodies. The basic need then is for sodium. Most patients can be treated adequately with isotonic saline if the renal function is adequate. The state of renal function should be born in mind since the ratio of sodium to chloride in the plasma is 3 to 2 and not 1 to 1 as it is in isotonic saline. With an adequately functioning renal mechanism, the needed sodium will be retained and the excess chloride excreted. Since this mechanism cannot always be relied upon in the elderly patient or in the diabetic with arteriosclerosis, it may be necessary to supply needed base in the form of molar sodium lactate (two ampules of 40 c.c. each containing 40 MEq. of sodium lactate may be added to a liter of isotonic saline). However, in severe acidosis, the body is relatively unresponsive to insulin and may be unable to catabolize the lactate at a rapid enough rate to make the sodium available as rapidly as needed. In this situation, 500 c.c. of 5 per cent sodium bicarbonate solution intravenously may be lifesaving.

Potassium depletion.—There is marked withdrawal of K^+ from the serum as improvement in the acidosis occurs. The increased utilization of glucose and repletion of intracellular potassium may cause severe hypopotassemia. This may occur as early as four hours after the beginning of therapy. The earliest evidences of decreased serum potassium are found in lowered and inverted T waves in the electrocardiogram. It is well to repeat leads 1 and 2 of the electrocardiogram at four, eight, twelve and twenty-four hours after therapy has been started. Marked muscular weakness is a later symptom and the situation should be noted on the electrocardiogram before this occurs. When potassium is needed, 40 MEq. of potassium phosphate may be given per hour. However, before K^+ is administered, the patient's renal status must be judged by urinalysis, BUN and urine output, since serious potassium toxicity may occur if renal insufficiency is present. In this situation, potassium should be administered with great caution if at all.

TABLE IV. TREATMENT—FLUIDS

1. 1500 to 2000 cc. normal saline I.V. stat. 3000 to 8000 cc. may be needed in 24 hours.
2. Precautions as to circulatory state and ability of the kidney to handle the fluids given.
3. May need 5% $NaHCO_3$ if in severe acidosis.
4. Potassium—determine need by E.K.G. or laboratory test. When needed may give 40mEq. of potassium phosphate per hour. Watch patients' renal status carefully.
5. Order blood sugar, CO_2, Cl, Urea, Catheter, Gavage.

Whether or not to use I.V. glucose solutions is I believe an individual matter which can be decided only after observing how rapidly the blood sugar is being reduced. Early and injudicious use of I.V. glucose often confuses the laboratory and clinical picture and makes it difficult to determine subsequent insulin dosage. I personally do not advocate the use of intravenous glucose until the acidosis is under control and the blood sugar near normal.

After Care

When the urine is free of acetone and the glycosuria is 2 plus or less, the acute phase of the illness may be considered over. During the next twenty-four hours the patient should be on a liquid to soft diet and insulin dosage determined by the amount of glycosuria. It is usually possible to re-establish the standard diabetic program within forty-eight hours.

Summary

Diabetic acidosis and coma, their differential diagnosis and treatment have been reviewed. Early and aggressive treatment may be lifesaving in this medical emergency.

MM

Ocular Palsy in Temporal Arteritis

Medical Progress

Part II

C. MILLER FISHER, M.D.
Boston, Massachusetts

WHILE preparing this report on oculomotor disturbances, the author found that the literature contained no comprehensive account of the more general central nervous system manifestations of temporal arteritis which, when added to the visual and ocular signs, might serve to complete the neurologic part of the clinical picture.

Therefore, a review of all the reported cases of temporal arteritis with cerebral complications was undertaken; this, however, appeared to be of limited value when confined to a single form of arteritis. It was then decided to expand the review to include the neurologic features of each of the several arteritides (periarteritis nodosa, granulomatous angiitis, *et cetera*) the whole to be prefaced by a brief outline or classification of the various forms of arteritis. The aim has been to demonstrate the relationship, if any, of temporal arteritis to the other arteritides and at the same time to point out the ways in which it differs from them clinically and pathologically.

The cranial arteritides, whose etiology is more or less understood, have been purposely omitted from the tabulation below, for example, meningovascular syphilis and arteritis secondary to pyogenic and tuberculous meningitis. Schistosomiasis,[26] histoplasmosis,[27] mucor mycosis, torula and other fungi may produce a granulomatous meningitis in which the cerebral blood vessels become involved. Typhus, malaria and trichinosis can also evoke a cerebral arteritis. Nematode infestation has not been reported to involve cranial vessels, although

Part III, the final section of this paper, will follow in a future issue.

incriminated in the etiology of angiitis in other parts of body. Cerebral sarcoidosis will be discussed under the neurologic manifestations of granulomatous angiitis.

The Arteritides—A Classification and Outline

The cause of each of the arteritides remains obscure, although they are commonly regarded as the manifestation of an allergic process. It would, of course, be most important to find a common thread of etiology running through the various types but, on the grounds of clinical and pathologic features, the formulation of a unitary concept is not warranted at present. The following list of the arteritides, although no doubt creating some artificial divisions, may serve to show temporal arteritis in some semblance of its proper perspective within the general field of arteritis.

1. *Periarteritis nodosa* (classical periarteritis) is a focal necrotizing process involving medium-sized and small muscular-type arteries of many viscera. The lesions are related to bifurcations and are of various ages. An important distinguishing feature of this type is its tendency to spare the pulmonary vascular tree; moreover there are no lesions in the splenic arterioles or in non-vascular collagenous tissue. The inflammatory infiltration usually does not contain giant cells. The lesions may be visible only microscopically and for that reason the term "nodosa" is not wholly appropriate. Asthma and eosinophilia do not occur clinically.[28]

2. *Allergic granulomatous angiitis with asthma and eosinophilia* (Churg and Strauss)[29] (granulomatous angiitis) consists of widespread necrotizing vascular lesions of the type seen in periarteritis nodosa, and, in this variant, the lungs are characteristically involved. A typical tissue alteration is found in the walls of affected vessels and in the non-vascular collagen system, consisting of a severe fibrinoid change, granulomatous proliferation of epithelioid and giant cells and, at times, necrosis of eosinophilic exudate. The clinical syndrome includes severe asthma, fever, eosinophilia and vascular embarrassment in various organs. This variety is to be distinguished from Group 1 by the presence of giant cells, the involvement of the pulmonary vasculature, the presence of extravascular lesions and the clinical occurrence of asthma and eosinophilia; it differs from Group 3 in the presence of giant cells and the occurrence of asthma and hypereosinophilia.

3. *Hypersensitivity angiitis* (Zeek)[28] is characterized by an acute fibrinoid necrosis of small vessels (small arteries, arterioles and venules) without a predilection for localization at bifurcations. The inflammation may involve the pulmonary vessels and splenic trabeculae, and small foci of necrosis may be found in non-vascular collagen. Giant cells are not seen. Lesions are rare in the intestine. The lesions are microscopic as a rule, tend to be of the same age and granulation tissue is not found around the involved vessels. This type is particularly related to drug and serum reactions.

4. *Wegener's granulomatosis,*[30] a rare disease closely allied to periarteritis nodosa, is characterized especially by necrotizing granulomatous lesions of the upper air passages and lungs. In addition, a generalized necrotizing vasculitis of arteries and veins is more or less widely disseminated, the lungs almost always being involved. These lesions show the classic changes of periarteritis nodosa. A glomerulitis is regularly found, as well as disseminated visceral granulomata, splenic trabeculitis, and massive multiple necroses in the spleen associated with an extensive central arteritis. The clinical picture consists of chronic suppurative sinusitis, ulcerative lesions of the mucosa of the mouth and larynx, cough and dyspnea, otitis media, arthritis and evidence of severe renal damage and failure. It is possible that Wegener's granulomatosis is merely a special form of granulomatous angiitis in which lesions of the upper respiratory tract are unusually prominent. In none of the reported cases (some thirty in all) have intracranial lesions been described.

5. *Unclassified Periarteritis,* as a group, provides a temporary location for the not uncommon cases that cannot be easily arranged within the confines of the first four groups. Usually the atypical features appear to be minor; sometimes giant cells are present when not anticipated, or vice versa; or asthma and/or eosinophilia is missing when the remainder of the picture calls for its presence. It is not unlikely that as knowledge accumulates, regrouping will become necessary.

Rose and Spencer,[31] (1957) finding difficulty in fitting their 111 cases into the above groups, simply classified them into two groups, chiefly according

to whether or not the lungs were involved. The group with involvement of the lung was different from the group without involvement of the lung in the following respects: a respiratory illness preceded the polyarteritis, a blood eosinophilia of 1500 per cu. mm. or more was present and nasal or middle ear granulomas occurred; pathologically, the differences included the occurrence of pulmonary arteritis, necrotizing pulmonary lesions and a granulomatous polyarteritis; the necrotizing or granulomatous lesions were often not demonstrably related to arteries; numerous eosinophils were contained in the arteritic lesions and giant cells were found in the exudate.

6. *Temporal arteritis* (cranial arteritis). Although it is now appreciated that in temporal arteritis many other large arteries of the body are involved—internal carotid, external carotid, common carotid, innominate, subclavian, aortic arch, pulmonary, coronary, thoracic and lumbar aorta, splenic, celiac, renal, mesenteric, iliac, and femoral —the present terminology might well be retained with advantage for the time being because of precedence and custom and because it connotes the approximate site of the most important *clinical* features of the illness, namely headache and blindness. The fundamental lesion is a mildly destructive inflammatory process involving the arteries just listed; lymphocytes, plasma cells, macrophages and polymorphonuclear leukocytes are found throughout the thickened vascular wall but especially in the media and giant cells are characteristically present. Subintimal proliferation of connective tissue narrows the lumen and thrombosis is occasionally added. Vascular nodules and aneurysms are usually not found. Many external cranial vessels other than the temporal and occipital arteries are affected. Allergy and hypersensitivity play no overt part in the etiology of the disease. Almost all patients are elderly. The disease differs from periarteritis nodosa in that the latter involves only small vessels and scarcely ever the temporal arteries, and in this regard cases which would form a bridging link between these two forms of arteritis are extremely rare. On the other hand, cases in elderly persons have been reported in which the aorta and its branches showed a giant cell arteritis when the temporal arteries were apparently spared, suggesting a relationship with idiopathic arteritis of the aortic arch and its branches (Group 7). The term "giant-cell arteritis" has been suggested as more suitable than temporal arteritis but not all cases coming to autopsy have shown giant cells in the vascular inflammation.

7. *Idiopathic arteritis of the aortic arch and its branches* (Takayasu's disease,[32] aortic-arch syndrome, pulseless disease). Although the arteritic lesions in this condition are more widespread than the name indicates, the term has the merit of focusing attention on the site of the most striking clinical effects, namely, the aortic arch and the carotid and subclavian arteries. The disease, a relatively rare entity, is characterized by a mildly destructive chronic inflammation of the stated vessels, the lesions showing macrophages and lymphocytes, and usually giant cells as well. The lumen of the arteries becomes occluded by subintimal connective tissue proliferation, or by organizing thrombus. The thoracic aorta, coronary ostia, and axillary vessels may also be involved. Several authors have concluded that tuberculosis or syphilis has been responsible in their patients and these diseases must always be excluded.

Giant cell inflammation of the aorta and its large branches forms such a striking and integral feature of both Takayasu's disease and temporal arteritis that one might anticipate that a close relationship existed between the two. However, there are equally prominent dissimiliarities: the former affects the elderly, while the latter almost always occurs in women under the age of thirty-five; temporal arteritis has never been reported to produce the aortic arch syndrome which is the principal feature of Takayasu's disease; idiopathic arteritis of the aortic arch and its branches has never been shown to involve the temporal artery; and, whereas the visceral and lower limb arteries have not been the site of arteritis in Takayasu's disease, they have usually been involved in the cases of temporal arteritis studied pathologically. Possibly the two forms of arteritis are closely related, one affecting the young and the other the elderly, a "juvenile" and "senile" arteritis, with *age* accounting for the pathologic and clinical differences.

8. *Rheumatic arteritis* is an acute inflammation of the small arteries, usually of heart and lung, occurring in fulminant rheumatic fever and carditis. Usually the patient is young and the clinical picture is predominantly cardiopulmonary.

9. *Thromboangiitis obliterans* (Buerger's disease). With the advent of further knowledge of

the behavior of atherosclerosis in the aorta and lower limbs, the frequency with which Buerger's disease is diagnosed has fallen correspondingly. A recent review of the literature[33] shows that an actual arteritis (in the usual sense of the term) has never been demonstrated in thromboangiitis obliterans and, therefore, the existence of a specific disease entity, thromboangiitis obliterans remains to be demonstrated. In none of the reported cases of *cerebral* thromboangiitis obliterans has inflammation of the cerebral arteries been found. In several instances, brain infarction has resulted from (or at least been associated with) unrecognized occlusion of the internal carotid artery. The "white vessels" over the area of softening appear to result from stagnation or stasis thrombosis with subsequent organization of the clot. When carotid angiitis is found in the vessels in the neck, temporal arteritis or Takayasu's disease should be considered. The diagnosis of cerebral thromboangiitis obliterans should probably not be made until its clinical, pathologic and etiologic aspects are clarified. Neither temporal arteritis nor idiopathic arteritis of the aortic arch and its branches has been reported to involve the lower limb arteries to a degree sufficient to produce ischemic manifestations but giant-cell arteritis of the femoral artery has been found in the amputated lower limb of a patient suspected of having a more generalized arteritis.[34]

Localized Carotid Arteritis

From time to time, a localized form of carotid arteritis is attributed to inflammatory involvement of the vessel as it passes through the cavernous sinus. For example, Kissel and co-workers[35] described the case of a man, aged thirty-two, who suddenly developed a right hemiplegia and aphasia three weeks after a "grippe-like" febrile illness. Death occurred two days later and at autopsy the left internal carotid artery and its terminal branches were distended and occluded by recent thrombus. Microscopically, the walls of the internal carotid artery (especially the segment within the cavernous sinus) were disorganized, and the elastic lamina was destroyed. The adventitia showed an infiltration of round cells and the authors concluded that the primary lesion was an arteritis originating in the cavernous sinus which caused thrombosis to extend distally and proximally along the internal carotid artery. The pathologic description is brief and the photographs are not clear and one might hesitate to accept the author's interpretation of the illness. Tolosa's case[36] was most unusual. A man, aged forty-seven, for one month had left orbital pain associated with involvement of the third, fourth, fifth and sixth nerves. An arteriogram showed narrowing at the carotid siphon for which surgical exploration was carried out, followed by death. The internal carotid artery within the cavernous sinus showed a cuff of granulation tissue which resulted in narrowing of the lumen without occlusion.

Cope and Jones[37] reported a case in which a left hemiplegia developed about five weeks after right ophthalmic herpes zoster. After discussing the only three previously reported cases of a similar nature, the authors inclined to the view that the hemiplegia was due to the virus invading the nearby pyramidal tract from the trigeminal ganglion. The possibility should be considered in these cases that carotid arteritis had developed secondary to the ganglionitis, resulting in carotid thrombosis or embolism.

Neurologic Manifestations of Temporal Arteritis

(Excluding visual and oculomotor disturbances)

Unfortunately, in many of the reported cases, the neurologic information is so brief that a clear picture of the patient's condition is precluded. Detailed neuropathologic reports are few, and often incomplete, insofar as they fail to draw a satisfactory clinico-pathologic correlation or explain the mechanism by which the brain damage arose. The group of pathologically-studied cases will be summarized first, and second, the cases in which only the clinical findings were available. In the clinical description of each case, only the neurologic data will be presented and it should be remembered that the patient usually showed the typical picture of temporal arteritis as well as the manifestations of nervous system involvement. Because visual disturbances resulting from involvement of the optic nerve have been reviewed on several occasions by other authors, they have largely been omitted here.

In Gilmour's[23] (1941) Case 2, the patient developed a flaccid left hemiplegia eight days before death. The internal carotid stems (from the clinoid process to the bifurcation) were greatly thickened. The walls showed a diffuse inflammatory infiltration with monocytes and giant cells, and

the lumens were occluded by thrombus. The state of the other major branches of the circle of Willis was not mentioned. The temporal arteries were not examined, but clinically the patient had severe pain in the left side of the head.

In Gilmour's Case 3, the patient complained of pain in the neck and temples, vertigo, tinnitus, and later the left arm became weak. The cerebrospinal fluid contained 360 mg. of protein and 650 white cells per cu. mm., chiefly lymphocytes. The walls of the internal carotid arteries in the region of the clinoid processes were greatly thickened and the lumens were occluded by thrombus. Microscopically, the changes were the same as in Case 2. The temporal arteries were not examined. There was a cerebral infarct and, in addition, numerous areas of hemorrhage throughout pons and midbrain. It might be assumed that in this case tentorial herniation had complicated the cerebral infarction.

Cooke et al[6] described two patients with cerebral manifestations. Patient 3 had been temporarily irrational and disoriented at the height of her illness, and at autopsy there were cerebral softenings and many of the smaller vessels contained antemortem thrombi, either embolic or thrombotic. The walls of the cerebral arteries were free of inflammation. Patient 6 developed severe giddiness, nausea and vomiting ten days after admission. Three days later, it was noted that the patient was totally deaf in the left ear and partially deaf in the right. For the next seven days she was irrational and incontinent of bladder and bowel. Her condition then improved and hearing returned so that she could hear the normal voice at 2 feet in either ear. Orientation was temporarily regained but two weeks later the patient died in coma (not further described). In the brain, tiny softenings were common in the subcortical white matter and the related vessels showed thrombosis. Some of the thrombi contained many polymorphonuclear leukocytes but there was no evidence of any inflammatory reaction around the vessels. The nature of the cerebrovascular disease was not fully explained.

Cardell and Hanley's[11] patient had typical temporal arteritis. The later part of his illness was marked by right frontal headache, vertigo, dysphagia and dysarthria, weakness of the right facial muscles, nystagmus, and right palatal palsy. At autopsy, there was giant cell arteritis of both internal carotid arteries in the region of the origin of the ophthalmic artery but the lumen of the vessels was patent. There was no inflammation of any of the other major cerebral vessels and the cause of the neurologic symptoms was not found.

Ritama's[24] (1951) case was one of a woman, aged sixty-three, who after ten years of deforming arthritis developed dyspnea on effort, dizziness and headache. One week after admission to the hospital an "apoplectiform fit" occurred. The patient vomited, speech became slurred and the left hand was helpless. These symptoms cleared in twenty-four hours. A Babinski sign was present bilaterally. The blood pressure was as high as 200/120. Having been somnolent and disoriented for some days, the patient died seven weeks after admission. Pathologic examination showed a giant cell arteritis involving both internal carotids, the common carotids, the thoracic aorta, the coronary arteries and the "cranial arteries" of different size. The temporal arteries were not examined but the most proximal part of one external carotid artery was affected. The left internal carotid artery was surrounded by abundant soft granulation tissue in the region of the carotid canal. "The brain tissue revealed numerous ischemic necroses particularly involving the cortex. The left posterior inferior cerebellar artery was thrombosed. The hypophysis was disintegrating." The surface of the aorta near the aortic valve cusps was covered with a thin fibrinous thrombus. The pathologic findings justify accepting this case as temporal arteritis in the absence of an examination of the temporal arteries. The carotid arteries were not occluded by thrombus and the cause of the cerebral infarctions was not stated. Cerebral embolism was possible in view of the presence of intimal thrombus near the aortic cusps. Hypertensive atherosclerotic encephalomalacia also might have been a factor although the predominantly cortical location of the softenings would be against this interpretation.

In Case 3 of Meneely and Bigelow[38] (1953), the patient had episodes of sudden loss of consciousness and falling without convulsions. Examination disclosed right wrist drop, slight atrophy of the left foot, and mild right facial weakness. A left carotid arteriogram showed failure of the vascular tree to fill. The patient lapsed into coma and died. Pathologic study showed advanced atherosclerosis of both internal carotid arteries, and, in addition, the changes of granulomatous arteritis with foreign-body giant-cell reaction. The thrombi in both of these vessels had virtually obliterated the already-narrowed lumen and there was wide-

spread encephalomalacia. Several of the small intracerebral vessels showed changes suggestive, but not typical of a granuloma.

In Case 13 of Heptinstall et al.[15] a man, aged sixty-six, was admitted for fatigue, anorexia and temporal headache with more recent drowsiness and weakness. He died in coma three weeks after admission. The blood pressure was 260/140. At autopsy there was an infarct of the right lobe of the cerebellum and occlusion of the right vertebral artery. The temporal and facial arteries also had thickened walls and narrowed lumens. Characteristic arteritic changes were found microscopically in the right and left facial, right vertebral, right occipital and left external carotid arteries as well as in the temporal arteries. In their Case 14, the patient, aged sixty, had sacral pain, pain across the shoulders, loss of weight, tiredness and left-sided headache. During the next three months he had severe pain in both temples with blurring of vision and occasional diplopia. Soon afterwards he became blind in both eyes, then disoriented and developed first a left hemiparesis, then a right hemiplegia with subsequent death in coma. The brain showed extensive softening of both occipital lobes and both vertebral arteries were thrombosed where they entered the skull and thrombus was also present in the posterior cerebral arteries. Microscopically, the following arteries were affected by giant-cell arteritis: aorta, right and left temporals, right internal carotid, right external carotid, right and left common carotids, right and left vertebrals with intravascular thrombosis, right and left ophthalmics, hepatic, right popliteal and right subclavian. The inflammatory changes were frequent in the intima while the media showed fewer lesions. These two cases are of special interest because they are the only reported examples of arteritic involvement of the basilar-vertebral system, the lesions presumably lying intracranially.

McMillan's case[39] (1950) was a man, aged fifty-eight, who died of broncho-pneumonia eight days after the onset of a left hemiparesis. At autopsy, the right cerebral hemisphere was swollen and the right internal carotid and middle cerebral arteries contained thrombus. There was a giant cell arteritis of the aorta and left common iliac artery. Apparently the carotid vessels in the region of the thrombus did not show inflammatory changes and, therefore, the exact cause of the thrombosis could not be stated. The temporal arteries were not examined pathologically and there was no clinical evidence that they were affected; the case is therefore included only because of the typical aortic and iliac lesions. It is conceivable and even likely that the disease "temporal arteritis" occurs without actual involvement of the temporal arteries.

The next four cases illustrate the existence of arteritic lesions in the carotid (and other) vessels without cerebral signs. Barnard's[40] (1935) case was of a man, aged sixty-three, with the typical signs of temporal arteritis. At autopsy, there was a diffuse giant cell arteritis of the cervical portion of the internal carotid arteries and their intracranial portion in the cavernous sinus, and of both coronary arteries. The lumen in each instance was greatly narrowed by subintimal connective tissue proliferation. The intracerebral arteries were not affected. The aorta was not examined. There was a small (1 cm.) hemorrhage in the lenticular nucleus of the brain which had, apparently, not evoked clinical manifestations. The author interpreted the pathologic changes as those of tuberculous arteritis.

In Sproul's[41] (1942) case there was good clinical evidence of temporal arteritis (not pathologically verified) and, at autopsy, histologic study revealed arteritis with giant cells involving the carotid, innominate, subclavian, pulmonary, celiac, mesenteric, renal and iliac arteries.

In Greenfield's[17] case, although there were no neurologic complaints, the internal carotid arteries showed extensive medial destruction with replacement by a granulomatous thickening containing giant cells. On both middle cerebral arteries in the fissure of Sylvius, several small rounded or lentiform granulomas, one of which contained a giant cell, and numerous small foci of lymphocytic infiltrations were present in the *adventitia*. The media and intima showed no infiltrations. The anterior cerebral and anterior choloidal arteries were similarly involved but to a lesser degree. The temporal arteries were not examined. Among the many large vessels involved in Fragenheim's[34] Case 1, the common, internal and external carotids were included, but the patient had no abnormal neurologic signs. This case was unusual in that the giant-cell inflammatory process extended to the small bronchial arteries, the intraglandular thyroid arteries and the small vessels of the skeletal musculature, forming a link between temporal arteritis and granulomatous angiitis.

As already pointed out, in the majority of these cases, a good clinico-pathologic correlation cannot

be achieved. Not only is the clinical picture sometimes not explained by the pathologic findings but also, at times, the vascular abnormality cannot be correlated with the parenchymal lesion. Embolus is not always distinguished from thrombus. The arteritis evokes symptoms by causing vascular occlusion and cerebral infarction, large or small. The vessels become obstructed partly by thrombus formation, chiefly by subintimal thickening. The carotid or basilar-vertebral system may be involved but giant cell inflammatory lesions of arteries lying within the dura appear to be uncommon, the only three examples being those described by Greenfield, Heptinstall et al., and possibly Meneely and Bigelow.

In some fifteen additional cases of temporal arteritis studied only clinically, neurologic symptoms and signs have been recorded; however, the description is sometimes vague or ambiguous, making interpretation impossible. Bain's[42] (1938) patient became disoriented about two weeks after the onset of his illness; recovery was complete. In the case cited by Sprague and MacKenzie[43] (1940) it was reported, "The patient's mental processes, ordinarily quite alert, became very sluggish and some of his friends wondered if he had sustained a slight cerebro-vascular accident." The patient did not recover his quickness of thought and action.

Schafer and Sanders'[44] (1942) patient, at the height of his illness, was delirious and had slurred speech. The patient reported by Post and Sanders[45] (1943) deteriorated mentally six years after having temporal arteritis but no evidence was provided to indicate that the two conditions were related. At the onset of her illness, Curtis'[46] (1946) patient was seized with a whirling sensation accompanied by pain in the back of her head. The illness progressed to the full-blown picture of temporal arteritis and bilateral blindness occurred. Three months from the onset of the disease, the patient developed a left hemiplegia and died five days later. An autopsy was not performed.

In Case 2 of Cohen and Harrison[47] (1948) abduction of the right shoulder was limited and the right deltoid muscle was wasted. Robertson's[48] (1948) Case 1 was that of a man who, four months after the acute phase of temporal arteritis, underwent a surgical operation and postoperatively became confused for several days, but a relationship with the arteritis is by no means certain. In Case 4, a man aged sixty-seven, suspected of temporal arteritis (not biopsy-proved) developed a complete right twelfth cranial nerve palsy. Dick's[8] patient was confused and drowsy but no further details were provided. Cloake[49] (1951) briefly referred to a patient of his who developed signs of myelitis with severe, but rapidly improving, paraplegia and corresponding sensory disturbance.

In Case 1 of Kendall[14] the patient, aged seventy-eight, was at times mildly confused and delirious. In his Case 3, the patient complained of giddiness, nausea and ringing tinnitus and on examination nystagmus and nerve deafness were found. The possibility of a co-incidental Ménières syndrome should be considered here. In Case 7 of Heptinstall et al.[15] the patient was still complaining of headache and dizziness one year after the acute stage of her illness. Meadows[19] briefly referred to a patient who died from carotid artery occlusion and hemiplegia soon after the onset of blindness. Two of his patients had evidence of dementia probably not related to the arteritis.

Recently, the first case of temporal arteritis with cerebral symptoms encountered at the Massachusetts General Hospital was seen in consultation with Dr. W. H. Timberlake.

Case 5.—The patient, aged seventy-six, had severe occipital headache for about three weeks beginning in late October 1957. For several weeks previously there had been malaise, anorexia and loss of weight. The headache which at no time extended anterior to the ears, stopped about November 19 and six days later the patient became totally blind in the left eye, overnight. Three days after this, vision in the right eye was noted to be poor. On examination, there was no vision in the left eye and an extensive lower temporal field defect in the right. The temporal arteries were pulseless but not enlarged, firm or tender. Biopsy of the left superficial temporal artery showed a typical giant-cell arteritis. On Meticorten therapy the patient felt better generally but vision did not improve. Meticorten was discontinued after about five weeks (January 7, 1958) and the patient's course was uneventful until February 27 when his wife reported that the right hand had been transiently limp twice in one day. The patient claimed that on three occasions in the previous four days there had been brief spells in which the right hand shook. On examination, the patient was disoriented for time and place, did not recognize his physician, made a few mistakes in naming objects, was quite unable to do simple arithmetic and had a Babinski sign on the right side. Meticorten was restarted and during the following five weeks despite large doses (up to 150 mg. each day) the patient's course was punctuated by episodes whose nature was not established with certainty: On March 5, he told his wife that his right arm had been weak in the morning; March 8, according to the wife, a slight attack in which legs buckled under him; on same day

while sitting in lounge, weakness of right arm and leg noted and patient babbled incoherent answers for three minutes; March 11, momentary spell of confusion and weakness of the right hand which also shook; March 12, patient "fell stiff" on floor, eyes rolled up, no shaking; electroencephalogram markedly abnormal on left side, anticoagulants started and continued for six days; March 17, brief dizzy spell; March 22, weakness of left leg on walking to bathroom; March 23, right arm flexed rhythmically for several minutes; March 27, right leg collapsed and patient fell, did not become confused, arm not affected; March 29, difficulty finding words. From February 27 to March 27, the patient was more or less disoriented, slightly dysphasic and the visual field defect was found to vary considerably. Neurologic examination was otherwise normal and the patient's course was always afebrile. The carotid pulsations were of normal force. The patient later claimed he "passed out" in his spells. He was discharged April 6 on anticonvulsant medication. There were no further spells but five days later occlusion of the left femoral artery occurred and the foot became gangrenous. The patient remained confused and his condition gradually deteriorated, death taking place eight weeks after discharge from the hospital. A postmortem examination was not made and the role, if any, of atherosclerosis on the production of the complications was never determined.

Comment.—Many of the features of the patient's attacks suggested epileptic seizures but since it was reliably reported that sometimes paralysis of limbs had occurred without any preceding convulsive activity, transient ischemic attacks were also a good possibility. If the vascular occlusion of the lower extremity was caused by arteritis, it represents a most rare event. In Fragenheim's[34] Case 2, the patient developed gangrene of one lower extremity and femoral arteritis was found in the amputated specimen, but there was little or no evidence of a generalized arteritis.

From these assembled reports it would appear that involvement of the central nervous system in temporal arteritis is not uncommon. Delirium and confusion are mentioned most often but whether these symptoms are produced by involvement of the brain by the arteritis or are merely the "nonspecific" effect of a systemic disorder in elderly patients is not clear. Hemiplegia as a result of carotid occlusion is the next most frequent finding, followed closely by signs of involvement of the brain stem or eighth nerve viz. tinnitus, dizziness and deafness, manifestations of temporal arteritis which deserve more attention than they have heretofore received. Generally speaking, it is evident that a more accurate and detailed account of the neurologic manifestations of temporal arteritis is needed.

Malignant Melanomatous Complex Ovarian Teratoma with Small-Bowel Obstruction

NORMAN H. BAKER, M.D.
MALCOLM B. DOCKERTY, M.D.
Rochester, Minnesota

From the Section of Surgical Pathology and the Section of Surgery, Mayo Clinic and Mayo Foundation, a part of the Graduate School of the University of Minnesota, Rochester, Minnesota.

This case report tells the story of a malignant ovarian teratoma containing melanomatous elements that caused obstruction of the small intestine in an elderly woman. Only half a dozen such lesions have been recorded in medical history.

INTESTINAL obstruction associated with teratocarcinoma of the ovary is a rare clinical entity. The presence of such obstruction was not recorded in an extensive review of the literature by Peterson.[1]

Our report concerns an elderly woman who had a teratocarcinoma of the ovary complicated by obstruction of the small intestine.

Report of Case

A seventy-six-year-old woman was admitted to the hospital in February, 1959. Seven days previously, she had begun to experience cramping lower abdominal pain. This pain increased in severity and was associated with

nausea and vomiting that began forty-eight hours before admission.

The patient had been operated on in 1920 for obstruction of the small intestine caused by adhesions; at this time, 16 cm. of ileum had been removed and continuity had been re-established by end-to-end anastomosis.

On examination, she appeared to be reasonably comfortable and not in acute distress. The abdomen was moderately distended and revealed a lower midline and right lower quadrant scar. The intestinal sounds were present and slightly high-pitched. Peristaltic rushes were not heard. Pelvic examination disclosed a cystic mass about 8 cm. in diameter in the right adnexal region. This was believed to be ovarian in origin. Rectal examination was noncontributory.

A Levin tube was passed for continuous gastric suction, and fluids were given intravenously. She continued to pass small amounts of gas per rectum, and it was thought that she had partial intestinal obstruction.

Hematologic studies gave normal results except for a mild leukocytosis, the count being 11,800 cells per cubic millimeter of blood. The following values in milliequivalents per liter of serum or plasma were obtained: sodium, 109; chloride, 90; potassium, 3.7; carbon dioxide-combining power, 26. The blood urea measured 18 mg. per 100 ml.

Roentgenologic examination showed slight gaseous distention of the colon and probably of some loops of terminal ileum, with evidence of fluid levels.

Proctoscopy disclosed beginning sacculation and two diverticula at the 13-cm. level. At 15 cm., the intestinal lumen was greatly narrowed by sacculation and the wall was fixed, making it impossible to pass the instrument any higher. There was no evidence of a neoplasm, and the mucosa was intact throughout.

The patient received a modified preoperative preparation of the intestine, using neomycin given through the Levin tube, which was clamped after each dose. Enemas were given until the returns were clear. On the fourth day following admission, a secondary lower midline abdominal incision was made, with excision of the old scar. Many adhesions were found when the abdomen was opened. The small intestine was greatly dilated as the result of a loop that was obstructed in the cul-de-sac in relationship to the cystic mass that had been noted clinically. This obstruction was released by blunt dissection. The mass was ovarian and was extremely necrotic as well as cystic. The tumor was considered

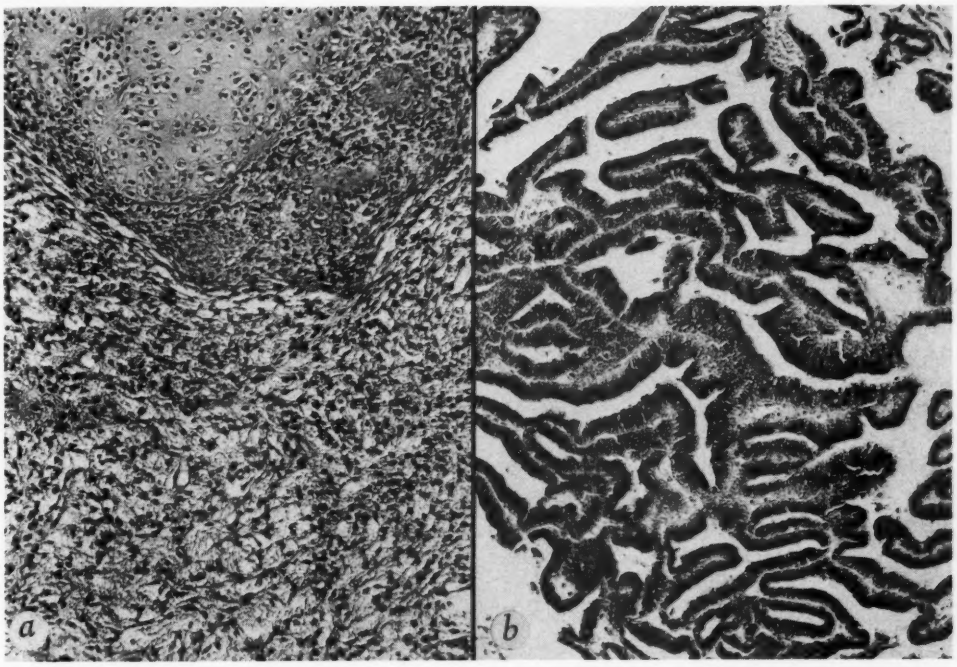

Fig. 1. *a*. Islands of cartilage, as shown here, represent the only benign components of this teratomatous tumor. This particular island lies in a spindle cell sarcomatous matrix. *b*. Low-grade papillary adenocarcinoma comprised the bulk of the tumor. Here, the pattern appears in pure form (both, hematoxylin and eosin; x150).

to be malignant, and the right ovary and adnexa were removed for diagnosis. Histopathologic study disclosed a hemorrhagic, necrotic, grade 4 malignant teratoma. The remaining ovary and the uterus then were removed in the usual fashion. Gross tumor was present on the loop of small intestine that had been obstructed. With the hope of palliation, this segment was removed and an end-to-end anastomosis was made. There was a remaining mass that was retroperitoneal and fixed to the sacrum. Because of the type of tumor and because the procedure would not be curative, this presacral mass was not disturbed.

The patient did well following the operation. During her hospital convalescence, a basal cell epithelioma was removed from her left cheek. She was dismissed with instructions to return in three months to be reevaluated for the possibility of roentgen therapy.

Pathologic Aspects

The gross pathologic material consisted of the uterus, both tubes, both ovaries and a 25-cm. segment of small intestine. Almost completely replacing the right ovary was a predominantly solid, friable, hemorrhagic, necrotic tumor weighing 75 gm. and measuring 8 cm. in diameter. No capsule worthy of the name was present. Over one aspect measuring 4 by 4 cm. was a meaty raw surface representing the zone of attachment to the removed segment of small intestine.

The cut surfaces were remarkable in that they displayed sizable zones in which the color was coal black. The remainder of the tumor was dark tan except for reddish patches of hemorrhage and yellowish zones of necrosis. All portions were extremely friable, and the central core of the tumor was excavated to form a cyst with ragged walls that measured 2.5 cm. in its greatest dimension.

The segment of small intestine was angulated and partially obstructed as a result of adherence to the ovarian tumor. Over its serosal surface, a zone measuring 4 by 4 cm. was deeply invaded by adherent malignant tissue. The atrophic uterus was not remarkable except for the presence of several malignant implants on its posterior surface. The uterine cavity was somewhat distended as a consequence of a small hydrometra, which apparently resulted from the presence of endocervical adhesions. The left ovary was atrophic. The fallopian tubes were normal except for several small tumor implants near the fimbriated end on the right.

Microscopically, the presence of several islands of cellular but benign cartilaginous tissue represented the only benign component in the right ovarian neoplasm (Fig. 1*a*). Chief among the malignant "ingredients" was adenocarcinoma, which varied in its degree of differentiation from grade 1 papillary adenocarcinoma (Fig. 1*b*) to solid sheets of undifferentiated cells (Fig. 2). It was impossible to ascribe a tissue or tissues of origin to this adenocarcinomatous moiety, since normal entodermal elements were not identified within the tumor.

In other broad zones, the neoplastic elements were spindle-shaped, sometimes being in a myxomatous matrix (Fig. 3*a*). Mitotic figures were fairly numerous. In the absence of identifiable cross striations, osteoid material or vascular spaces, it was not possible to designate this sarcomatous portion of the tumor more accurately than to state that it was of the spindle cell type. Admixture of the glandular and spindle cell elements at times produced a picture somewhat reminiscent of embryonal renal adenosarcoma, or Wilms's tumor (Fig. 3*b*).

The third main constituent of the malignant cellular mixture consisted of broad sheets of malignant epithelial cells containing heavy deposits of dark pigment (Fig. 4). The melanoblastic identity of these elements was established by the use of special techniques, including stains for iron. The uterine, tubal and intestinal involvement appeared to result from the processes of direct extension and peritoneal sedimentation. The endocervical obstruction was on an inflammatory basis.

Comment

The incidence of malignant transformation in teratomas varies widely depending on the tissue or organ from which the teratoma takes origin. Thus, ovarian teratomas are benign (dermoids) in perhaps 98 per cent of cases, whereas their testicular counterparts are malignant in a similar incidence. The majority, perhaps 75 per cent, of presacral, retroperitoneal and mediastinal teratomas are benign. However, the midline teratoma of the pineal gland is usually a malignant neoplasm.

Malignant changes originating within a teratoma may take on one of two forms. The first is anaplasia, which is confined to one of its constituent tissues, such as the squamous cell carcinoma that arises from the ectoderm of an ovarian dermoid. In a review of 222 malignant ovarian teratomas, Peterson[1] found that epidermoid carcinoma accounted for 88 per cent of the group, with adenocarcinomas and carcinoids making up the bulk

of the remainder. However, Peterson's analysis concerned itself chiefly with cystic ovarian teratomas that contained benign elements.

The second type of malignant change occurring in these neoplasms is what Willis[2] aptly described as "total malignancy." A complication of the more solid or embryonal or complex teratomas as contrasted with the more simple dermoids, this change features malignant neoplasia of several constituent tissue types, and its origin is from immature embryonic elements rather than from the mature tissue observed in the afore-mentioned category. Testicular teratomas are almost always of this mixed malignant category, and the intermingling in them of choriocarcinomatous, adenocarcinomatous and sarcomatous tissue occasions no surprise.

Thus, the tumor in our patient is an example of "total malignancy" in an embryonal teratoma, with only a small island of embryonic cartilage exhibiting any semblance of orderly growth and maturity. We have observed less than a dozen examples of such lesions in a study of more than 4000 cystic and solid ovarian neoplasms, which included more than 500 "dermoids." This tumor represented our first encounter with a primary ovarian teratoma containing malignant melanomatous elements. Otken[3] likewise attested to the rarity of primary ovarian melanoma, citing only seven comparable cases, some of them poorly documented. Peterson referred to a case that was mentioned in a personal communication from Teilum.[4] Other isolated examples may have eluded us in our review, but it would appear that the condition is indeed rare.

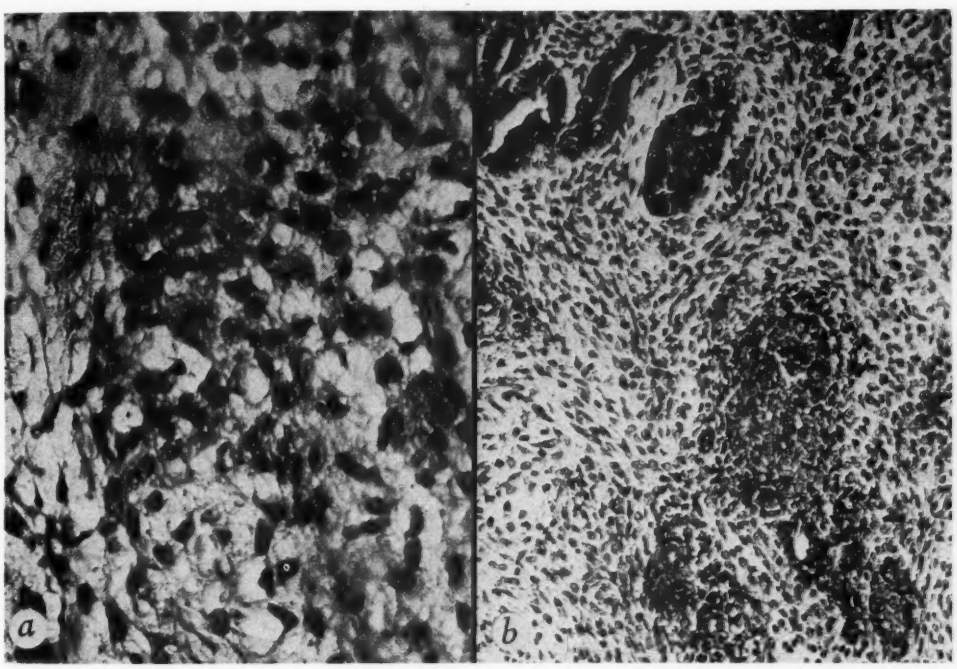

Fig. 3. *a*. Sarcomatous component featuring plump spindle cells in a somewhat myxomatous matrix (hematoxylin and eosin; x375). *b*. The intimate mixture of glandular and sarcomatous elements is reminiscent of renal adenomyosarcoma, or Wilms's tumor (hematoxylin and eosin; x175).

In our case, a careful search for blemishes on the skin and mucous membranes ruled out the possibility of metastasis from a melanoma in an extraovarian location. Likewise, in the teratoma itself, cutaneous structures were not identified. Accordingly, one must conclude that the melanomatous component derived from rather primitive neuroectoderm. An origin via the "retinal anlage" mechanism was considered but this concept was abandoned, since the teratomatous mixture with adenocarcinoma and sarcoma bore no resemblance

to the neuroblastomalike lesions reported by Hayes and Foote[5] and by others.[6-8]

As regards prognosis, it would appear from the literature that, even without the added handicap of the melanomatous moiety, surgical treatment offers little hope for cure in patients who have solid ovarian malignant teratomas. The vast majority of such patients exhibit metastasis at laparotomy. According to Peterson, the presence of adenocarcinoma or sarcoma in one of these neoplasms carries an unusually hopeless outlook. This is perhaps in keeping with the observation that solid malignant teratomas are much more aggressive than are their cystic "opposite numbers."

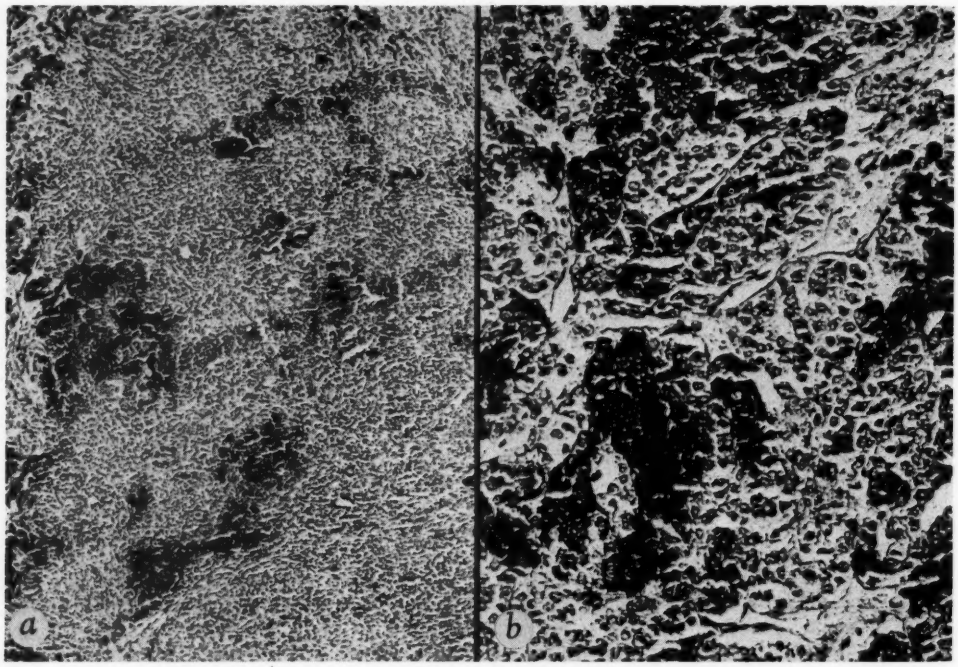

Fig. 4. *a.* Melanoblastic aspects of the tumor, showing irregular disposition of melanin (dark zones) within certain clusters of tumor cells (hematoxylin and eosin; x60). *b.* Clusters of pigmented and nonpigmented malignant melanoblasts arranged in alveolar grouping. Individual tumor cells are epithelial-like (hematoxylin and eosin; x200).

Summary

A case is presented of a seventy-six-year-old woman who had a malignant solid teratoma of the ovary in which the neoplastic mixture consisted predominantly of adenocarcinoma, sarcoma and malignant melanoma. Probably not more than half a dozen similar tumors have been recorded in the literature.

What's New in Congestive Heart Failure?

HENRY I. RUSSEK, M.D.
Staten Island, New York

Dr. Russek is Consultant in Cardiovascular Research U. S. Public Health Service Hospital, Staten Island 1, New York.

A GENERATION ago physicians prescribed rest, digitalis, diuretic therapy and dietary measures in the treatment of congestive heart failure. Today, although the general approach to the problem of management remains relatively unchanged, refinements in therapy, advances in our understanding of fluid and electrolyte disturbances, and agents permitting more vigorous treatment have increased our therapeutic effectiveness. The cardinal error in cardiac failure is the apparent inability of homeostatic mechanisms to distinguish between real fluid loss by the organism and a mere fluid shift engendered by weakness of the cardiac pump. With the onset of congestive failure, there is a diminution in cardiac output and a decrease in intracranial blood flow as a result of the hypovolemia. An intracranial volume center responds to this stimulus by initiating widespread vascular spasm (in which the renal circulation participates) and by adrenal cortical stimulation with the release of aldosterone. From the therapeutic viewpoint, the abnormal retention of sodium is the most important electrolyte disturbance in congestive heart failure. Although potent diuretic agents now available effectively block the reabsorption of sodium and water in the renal tubules, digitalis and decreased physical activity still remain the mainstay of therapy. Through the increased efficiency of myocardial function, as a result of digitalis therapy, a dramatic diuresis frequently occurs from improvement in intracranial blood flow and consequent re-adjustment of renal and adrenal cortical alterations. To date no fundamental differences have been found among the digitalis glycosides in their effect on the heart. Differences do exist, however, in clinical effect between one glycoside and another and may be due to variations in rapidity and degree of absorption, serum binding power, potency, duration of action, toxic cumulation and dissipation. Consequently, opinions differ as to the relative merits of digoxin, digitoxin, acetyl-digitoxin, and gitalin respectively for routine clinical administration.

Studies undertaken to determine the therapeutic differences in various glycosides administered by the parenteral route have shown that the best glycosides for severe tachycardia are cedilanid and digoxin, whereas the best drug for rapidity of effect was ouabain followed by digitoxin. Digitoxin and acetyl-digitoxin were equally effective in reducing cardiac size and were superior to ouabain for that purpose. Acetyl-digitoxin, cedilanid, and digoxin produced the greatest clinical improvement with the least electrocardiographic changes indicating

that there is no correlation between clinical digitalization and electrocardiographic response. There is some evidence to suggest that in patients with severe electrocardiographic changes due to myocardial damage, acetyl-digitoxin or digoxin should be preferred to digitoxin. This is based on the observation that long-lasting digitalization with digitoxin causes degenerative changes of the myocardium, while that with acetyl-digitoxin, digoxin, or cedilanid is not followed by similar changes. The minimal toxicity was found with cedilanid followed by acetyl-digitoxin and digitoxin. Contrary to expectation, digoxin was found more toxic than the other drugs tested. Nevertheless, when uncertainty exists as to recent digitalis intake, digoxin may be safer than other preparations because of its rapid dissipation. If severe toxic manifestations are feared, then cedilanid should be preferred. The rate of excretion for these drugs was as follows: ouabain was most rapidly dissipated followed by cedilanid, digoxin, gitalin, acetyl-digitoxin, and digitoxin. From all of these observations, digitoxin and acetyl-digitoxin appear to be the glycosides of choice. Digitoxin would be preferred for a short range course and acetyl-digitoxin for a long range course. Digitoxin was the only drug that could be given by the intramuscular route without causing excessive pain. Digitoxin, having a lower rate of elimination, gives a more constant level of digitalization. On the other hand, even though less toxic in a short term treatment, digitoxin may be more damaging to the myocardium on a long term basis because of electrocardiographic changes and arrhythmias, so that acetyl-digitoxin or digoxin might be preferred. Gitalin occupied an intermediary position and was considered as equivalent to a complete extract of digitalis with all its advantages and disadvantages.

It is generally agreed that the determinant of good therapy is the physician's knowledge of the application of any one of these preparations rather than the particular merits of the agent employed. The treatment of digitalis intoxication or toxicity consists primarily of stopping the digitalis until all evidence of overdosage has disappeared, the restriction of the patient's activities and the giving of potassium salts. Potassium may be administered in doses of 5 to 7.5 grams of potassium chloride in divided oral doses, and this dosage should be reduced or stopped after the therapeutic result has been achieved.

Diuretic agents are a valuable addition to our therapeutic armamentarium through their ability to block the reabsorption of sodium and water in the renal tubules. In practice, physicians frequently prescribe, in an arbitrary and haphazard manner, diets and drugs that strongly influence water and electrolyte balance. Such empirical procedures must continue until we can measure the state of intracellular water and electrolytes. In general, there are four groups of diuretics in common use today.

The mercurial diuretics, when given parenterally, are the most potent agents available. They have minimal side effects and produce a persistent diuresis and natriuresis. Parenterally administered mercurials are quite effective in the acute phase of treatment and are efficient for maintaining the edema free state.

Since the development of potent orally administered diuretic agents, however, interest has shifted from parenterally administered drugs. The organic chemist has provided the clinician with several diuretic agents which are both potent and relatively free of untoward pharmacological actions. The benzothiadiazine derivatives, notably chlorothiazide and hydrochlorothiazide, have proven to be the most effective oral diuretics at the present time. They produce an effective loss of sodium, chloride, bicarbonate, and potassium. *In vitro* studies reveal a definite carbonic anydrase inhibiting factor which, however, does not explain the diuretic response seen in clinical application. Refinement of the activity of chlorothiazide has been obtained by altering the basic structure of this drug. Hydrochlorothiazide and trifluoromethylthiazide have been developed and differ from chlorothiazide in certain features. The dose of hydrochlorothiazide necessary to produce an equivalent sodium loss is approximately one-tenth of that of chlorothiazide. Chlorothiazide has had the drawback of causing a great loss of potassium from the body and thereby inducing undesirable symptoms. To date, hydrochlorothiazide does not appear to have this effect. However, these drugs are not without other harmful effects: excessive potassium loss in the case of diuril and salt depletion with all of them. Chlorothiazide should not be given in full dosage, 2 gm. per day, for more than three or four consecutive days unless (1) potassium chloride supplements are used, and (2) plasma electrolytes are carefully followed. Potassium chloride therapy may be hazardous in edematous hyponatremic subjects and should be begun cautiously

with oral doses of 2 to 4 gm. daily. The safest therapeutic regimen appears to be the administration of chlorothiazide for three or four days followed by a three or four day rest period in order to allow K and chloride balance to return to normal. When more intensive diuresis is desired, a carbonic anhydrase inhibitor may be alternated with chlorothiazide. Carbonic anhydrase inhibitors, such as Diamox, produce hyperchloremic acidosis and thus may compensate for the hypochloremic alkalosis due to chlorothiazide or mercurial agents. Since all three agents can produce a negative K balance, potassium chloride supplements may still be necessary.

Carbonic anhydrase inhibitors such as Diamox have served as efficient diuretic agents in the mild to moderate states of edema with a low incidence of side effects. Their action is inhibition of the carbonic anhydrase in the renal tubular epithelium with resultant depression of hydrogen transport and hydrogen sodium exchange. These agents lose their diuretic effect in three to four days and therefor cannot be used continuously.

The xanthine diuretics, such as aminophylline, are still in common usage but their potency is poor when compared to the mercurials. However, the combination of the xanthine diuretic with one of the other groups of diuretics, frequently potentiates diuresis. Mictine and rolicton have proved to be effective oral diuretics, but their efficiency is limited to the mild to moderate states of edema and must be used intermittently to maintain maximum response.

Potent oral diuretics have made it possible to liberalize the cardiac patient's diet with respect to salt intake. This makes food more palatable thereby somewhat lessening the possibility that malnutrition will develop. Most patients with congestive heart failure show satisfactory improvement when treated with digitalis, diuretics, restriction of salt intake, and limitation of activity; their symptoms improve, and the edema is carried away by an increase in urinary volume. However, many such patients begin after a time to exhibit loss of responsiveness to diuretics and finally develop edema that seems to be intractable. The modifications in treatment necessary to restore responsiveness to diuretic drugs requires an understanding of the factors responsible for the development of intractable edema. There are many possible factors, and most of them fortunately may be recognized after careful physical examination or relatively simple laboratory tests. Among possible factors are inadequate digitalization, extremely low renal blood flow due to intrinsic renal disease or terminal congestive cardiac failure, complicating infections, masked hyperthyroidism, anemia, cardiac arrhythmias, chloride depletion, sodium depletion, low plasma-albumin levels, thiamine deficiency and other complicating states.

Repeated mercurial diuresis at short intervals may induce excretion of chloride in excess of sodium as compared to their relative concentrations in the plasma. The resulting serum electrolyte pattern may be described as hypochloremic alkalosis with hypokalemia. It may be avoided if ammonium chloride prior to or during the mercurial diuresis provides chloride to replace that lost in the urine. If diuresis is very profuse, several days should elapse between mercurial injections so that the disproportionate chloride loss is adjusted by dietary intake and renal excretion. Hypochloremic alkalosis, due to mercurial diuresis, may itself be responsible for unresponsiveness to diuretics. The treatment of hypochloremic alkalosis consists of the administration of chloride cautiously in the form of dilute hydrochloric acid or ammonium chloride (6 to 9 gm. daily), if there is significant hypokalemia, potassium should also be administered.

Repeated mercurial diuresis may result in a marked excretion of chlorides, sodium, and water. When water, and to a lesser extent chlorides, are replaced by oral intake of these substances but sodium intake is stringently restricted, a serum electrolyte pattern characterized by hyponatremia may result. Schroeder related a clinical picture to this electrolyte pattern and termed it the "low salt syndrome." This was characterized by hyponatremia, azotemia and refractory heart failure. It has become increasingly apparent that hyponatremia may result from a variety of mechanisms.

In the majority of cases of hyponatremia associated with heart failure, sodium depletion is *not* the responsible mechanism. In these there is no evidence of abnormal sodium loss externally and total body sodium is considerably increased. The hyponatremia results from water dilution of the extracellular sodium. The explanation for this disproportionate retention of water when sodium intake and excretion are minimal is not clear. Associated renal impairment may be an important if not an essential underlying factor. On the other hand, the impairment of water diuresis may be due

to increased secretion of the anti-diuretic hormone (ADH) in advanced heart failure rather than to renal impairment. It appears probable that the occurrence of dilution hyponatremia is itself a manifestation of advanced or intractable heart failure rather than a cause of it. However, at this state of heart failure, extreme restriction of sodium coupled with the administration of mercurial diuretics may further impair the renal excretion of water as well as of sodium instead of inducing diuresis and clinical improvement as they do when heart failure is less severe and still responsive to therapy.

Depletion and dilution hyponatremia may often be distinguished by a careful history of the sequence of development and the exact nature of the symptoms. Evidence should be sought of actual external sodium losses (profuse diuresis, paracentesis, thoracentesis, vomiting, diarrhea or salt-losing nephritis) and signs of dehydration, muscle cramps, weakness and a shock-like state. Treatment of depletion hyponatremia consists of increasing sodium intake by mouth in mild cases. Hypertonic sodium chloride (300 cc. of a 3% or 5% solution) is administered intravenously when the need is more urgent or the patient is unable to take sodium orally.

When hyponatremia is of the dilution type, one should consider carefully other possible causes of the clinical picture than hyponatremia. Overdigitalization should be corrected. Since intractable heart failure is often the reason for the hyponatremia, careful survey of all possible complicating factors or of imperfections in therapy should be made. If the heart failure is alleviated, the hyponatremia may be simultaneously corrected without direct attempts to correct the chemical change. Fluids as well as sodium should be restricted. (Similar to lower nephron nephrosis.) The fluid intake should not exceed the urinary output plus 500 cc. to allow for fluid loss by insensible perspiration. Administration of sodium orally or intravenously is contraindicated. The administration of potassium is rarely followed by a significant diuresis or clinical improvement despite the reported rise in serum sodium.

Various reports indicate that prednisone may dramatically influence refractory cardiac edema with a resultant marked increase in urinary output, restoration of response to mercurial therapy and significant diminution in congestive phenomena. It has been postulated that prednisone, in such instances, may antagonize the antidiuretic hormone of the posterior pituitary gland or reduce the output of the electrolyte-retaining steroid, aldosterone.

Blood pressure reduction alone by ganglion blocking agents has been found to influence favorably hypertensive heart failure in many patients with this disease. The observations seem to warrant the conclusion that in most patients the cardiac overload plays a more important part in the pathogenesis of hypertensive heart failure than an irreversible change in heart muscle. Reduction in blood pressure by ganglion blocking agents should therefore be considered when control of congestive heart failure is unresponsive to other means of therapy.

Recent observations indicate that administration of nitroglycerine sublingually is clinically effective in the relief of respiratory and retrosternal distress of paroxysmal nocturnal dyspnea. Studies in our laboratory have shown that nitroglycerine causes venous pooling in the lower extremities and splanchnic area with diminished venous return to the heart. Catheterization of the right side of the heart has demonstrated that nitroglycerine produces a prompt reduction in the pulmonary artery hypertension associated with failure of the left ventricle. Nitroglycerine therefore appears to have an important place in the management of patients with pulmonary artery hypertension and paroxysmal dyspnea associated with failure of the left ventricle.

Conclusion

The fundamental electrolyte disturbance in heart failure is the abnormal retention of sodium and the dramatic improvement in the outlook of patients with heart failure in recent years has been due to correction of this abnormality by a more effective use of very low sodium diets and mercurial diuretics. New potent oral diuretics when used alone or in combination with a mercurial may promote the mobilization of edema fluid when other measures have failed. These agents appear to be at least as potent as the organic mercurial itself and by their proper use congestive heart failure may be managed in many cases with a free salt intake or at least a liberalization of dietary measures. With proper understanding of blood electrolyte patterns in heart failure and with reasonable caution, it is possible to avoid serious electrolyte disturbances without surrendering the advantages of these agents fully utilized for maximum therapeutic effect.

Penicillin and the "Fleming Myth"

On Reading "The Life of Sir Alexander Fleming" by Andre Maurois

WESLEY W. SPINK, M.D.
Minneapolis, Minnesota

From the Department of Medicine, University of Minnesota Hospitals and Medical School, Minneapolis.

WHEN the Oxford team under Sir Howard Florey successfully treated with penicillin groups of experimentally-infected animals on May 25, 1940, a considerable impetus was given to the creation of the "Fleming Myth." The penicillin, extracted after arduous labor from the mold *penicillium notatum,* appeared to be nontoxic and highly efficient against lethal infections. The perfect "magic bullet" of Ehrlich seemed to be at hand. Would the acclaim and honor have come to Fleming during his lifetime without the efforts of the Oxford group? Possibly, but I doubt it. In this biography, André Maurois has presented a brilliant and lucid account of the circumstances that led to the discovery of penicillin, and of the struggles that were made in order to produce sufficient penicillin for use in patients. The author has also tried to penetrate the outer surface of this rather shy, reserved and inarticulate Scotsman. He presents him as a scientist possessed with an undeviating purpose, who was endowed with good health, and a brilliant and penetrating intellect.

It is given to some men, including warriors, statesmen, politicians and scientists, to have a myth built around them during their lifetime. This happened to Alexander Fleming. After the therapeutic virtue of penicillin had been substantiated, a "Fleming Myth" quickly arose. As he traveled about the world he was treated in some areas as a conquering hero, and in other places with saintly reverence. Maurois brings this out vividly in describing his trips to Spain, Greece and to India. Fleming was quite cognizant of this myth. Indeed, he kept a scrapbook of clippings, and he used to amuse himself, his friends, and his family in chuckling over some of the statements made about him. Through it all, Fleming never lost his sense of humor or his deep feeling of humility. I have the impression that he traveled about, not so much to be honored, but because he loved people, and he was curious about how other people lived and worked. He had had little opportunity or money as a research man to do much traveling. Furthermore, he was a loyal British subject, and a good ambassador.

Fleming is honored and known today for his discovery of penicillin. He shared in the Nobel Prize for this effort. However, Fleming himself did not consider this his greatest achievement. He made such a statement after a moment of reflection, on a visit to Minneapolis. He derived a greater sense of achievement from his discovery of lysozyme, a nontoxic, antibacterial substance found in human tears. This material, plus the simple techniques that he used in the laboratory for studying it, prepared him for the subsequent discovery and investigation of penicillin.

The essential background of Fleming's monumental achievement was his determined search for an antiseptic that was destructive for bacteria but harmless for the tissues and body fluids. He had witnessed the shortcomings of all antibacterial agents during World War I in the treatment of war wounds. He crystallized this objective early in his career when he was in the Inoculation Department of St. Mary's Hospital in London with Sir Almroth Wright as his Chief. He arrived at St. Mary's Medical School because of his love of athletics and because he had already established himself as a brilliant student. Unlike American medical schools, the medical schools in Britain, especially in London, emphasize athletic competition. Roger Bannister, the first human being to run a mile under four minutes, attended St. Mary's. Fleming was born into a large family on a remote Scotch farm. This isolated background probably accounted for his shyness, his reserve, and for his great love of nature, which may in turn have directed him into a biological science and medicine.

No biography of Fleming would be complete without more than a passing reference to his Chief, Sir Almroth Wright. Fleming joined Wright in 1906, after completing his studies in medical school.

Years later he was to succeed Wright as the Director of the expanded Wright-Fleming Institute at St. Mary's, retiring to the laboratory in 1955. Fleming's entire scientific life revolved about St. Mary's. Wright was the antithesis of Fleming. (For a vivid and detailed portrayal of this unusual man the reader should consult Leonard Colebrook's biography of Wright.[1]) André Maurois devotes considerable attention to him as a man and as a scientist. Of Irish origin, he was dynamic, voluble, brilliant and given to dogmatism. He cherished comradeship with accomplished people in all walks of life, including his close friend, George Bernard Shaw. He ruled the laboratory with an iron will. Fleming got along well with this genius because of his shyness, because Wright recognized his extraordinary ability, and because Fleming respected his Chief and spoke out very seldom.

When Fleming joined the team at St. Mary's the prevention and treatment of infectious diseases along modern lines were in their infancy. Wright was obsessed with the idea that the future was much brighter for immunotherapy than for chemotherapy, a position which he maintained even after the introduction of the sulfonamides. He was a firm advocate of the value of typhoid vaccine, which he had introduced, for the prevention of typhoid fever. In fact, he left the Army Medical Service and started his long career at St. Mary's because the military authorities did not look with enthusiasm upon his attempts to immunize army personnel against typhoid fever with a vaccine. He created many simple and classical techniques for measuring immune responses, such as the agglutination reaction for typhoid fever and Malta fever. He also originated the opsonic index for quantitating antibacterial immunity, a method in which the phagocytic efficiency of leukocytes for bacteria is determined. Fleming fell heir to the thinking and techniques of this great man. One of the outstanding scientific attributes of Fleming was the facility with which he employed simple procedures for quantitating the antibacterial efficiency of various chemicals.

While putting these thoughts together, I had occasion to chat with a distinguished internist in Minneapolis, Dr. Henry Ulrich, who is Emeritus Clinical Professor of Medicine of the University of Minnesota Medical School and still active in the practice of medicine at eighty-three years of age. A graduate of Johns Hopkins Medical School, he worked in the Inoculation Department of St. Mary's in 1907 and 1908. He went there to learn serology under Sir Almroth Wright, and occupied a bench in the laboratory next to Fleming. Dr. Ulrich spoke with glowing enthusiasm about the brilliance of Wright and his serologic procedures, including the opsonic index. Wright demanded absolute honesty in research, and his first question in evaluating the report of an investigator in the scientific literature was, "Is he honest?" Dr. Ulrich remembered Fleming as quietly going about his chores for Wright.

Fleming's first significant scientific contribution was reported in 1921, fifteen years after he had joined Wright. It was the discovery of lysozyme. He had observed that nasal mucus destroyed bacterial colonies on the surface of an agar plate. Human tears and egg-white were also found to be a source of this antibacterial agent. While studying lysozyme, Fleming developed a simple, but effective technique for measuring its antibacterial activity, which was to be employed later for penicillin. This consisted of making a gutter in the agar contained in a Petri dish, impregnating agar with lysozyme and placing it in the gutter, and then streaking different bacterial cultures at right angles to the gutter. As the lysozyme diffused from the gutter through the agar, susceptible bacteria failed to grow in its vicinity. Unfortunately, lysozyme was active against only less virulent bacterial strains. He presented his results on lysozyme before his Medical Research Club in London and "the reception accorded to the paper was cold beyond belief." But he was not deterred. He developed another simple technique for quantitating the antiseptic value of different substances. This was the slide-cell technique in which two glass slides are placed on top of each other separated "by five strips of Vaselined paper, placed at regular intervals at right-angles to the longest axis of the slides." Thus, there were four little spaces into which defibrinated blood mixed with bacteria could be placed, and the ends of the slides sealed. After a suitable period of incubation, the multiplying bacteria could be studied under the microscope and also the phagocytic activity of the leukocytes could be observed. The effect of antiseptics on leukocytes could also be noted.

Fleming relentlessly pursued his idea of finding an antiseptic that would destroy microbes, and yet not harm the cells of the body. As Maurois states, "In most of the great scientific discoveries there has been one part deliberate research and one

part luck. Pasteur, a man of unusual firmness of purpose who sought the truth with a combination of pure reason and experiment, was sometimes helped by chance." Pasteur was Fleming's great hero. All the world knows about Fleming's chance observation. Staphylococci had been planted on the surface of an agar plate. The plate became contaminated by a mold, and in the vicinity of the mold the cocci were lysed. Possessed with the experience of lysozyme he quickly saw the possibilities of the activity of this mold. He grew the undefined mold, made an extract, and found that it was highly active against pathogenic bacteria, and nontoxic when injected into animals. He published his classic paper on penicillin in 1929, at the age of forty-eight.

The recognition of penicillin was a great discovery and Fleming appreciated its potentialities in human disease, but he soon found out that he was faced with considerable difficulty in trying to obtain enough of the material for adequate studies in animals. He was not a chemist. He was a lone research worker and not surrounded by a team. He sought help from one of England's foremost chemists, Professor Harold Raistrick. But penicillin was an elusive and unstable substance and Raistrick and his associates were unsuccessful in extracting penicillin. But chance favored another prepared mind. Professor Howard Florey at Oxford suggested to a brilliant chemist with him, Dr. E. B. Chain, that he study lysozyme. Chain was intrigued by this substance and while searching through the literature on similar antibacterial substances, he came upon Fleming's paper on penicillin. Under the competent leadership of Florey, the chemical mystery of penicillin was pursued by Chain and his associates. The Rockefeller Foundation agreed to subsidize this study with a grant of $5,000. As a result, the Oxford team successfully isolated enough penicillin for some decisive animal experiments, which were published in 1940. It was a happy day in the life of Fleming when he read this report in the *Lancet*. He was now approaching his sixtieth birthday and it appeared that his goal had been reached.

Although the Oxford team had produced sufficient penicillin for evaluation in the laboratory, the large-scale production necessary for human purposes would require participation of the chemical industry. But England by this time had been plunged into World War II. Professor Florey then journeyed to the United States for help, and a fortunate chain reaction of accomplishments leading to large-scale production of penicillin resulted. He sought out Charles Thom, the mycologist who had identified *penicillium notatum,* and who was Chief of the Mycological Section of the Northern Regional Research Laboratory at Peoria, Illinois. In turn, he met Dr. Coghill, Chief of the Division of Fermentation at Peoria. Corn steep liquor was suggested in the fermentation of the penicillium culture and this was successfully used. Florey's old friend, Dr. A. N. Richards, had just been appointed President of the Committee of Medical Research of the National Research Council, and seeing the potentialities of penicillin in an all out war effort, Dr. Richards interested the Government of the United States in the production of penicillin. Finally, American industry became involved in the effort and by 1942 and 1943 penicillin had become available for the Armed Services. During this visit of Professor Florey to the United States, he stopped off to see Dr. O. H. Wangensteen at the University of Minnesota. Dr. Wangensteen invited a few of us to have dinner with Professor Florey, and during the course of the evening this mild-mannered Professor from Oxford unfolded the almost unbelievable story of penicillin.

By 1943 honor after honor was heaped upon Fleming. The "Fleming Myth" had started. He was knighted by his King, elected to the Royal Society, and shared with Florey and Chain in the Nobel Prize. He was to begin his travels about the earth acquiring further honor and fame. In between trips he was to be found at St. Mary's. Sir Almroth Wright had died in 1947, Fleming having become the Principal of the Institute in 1946. But one further event of major interest did occur in the life of Fleming, mixed with pathos and with romance. His wife Sareen, to whom he had been devoted for thirty-four years, died in 1949. This left Sir Alexander a very lonely man. In 1946 an intelligent Greek woman scientist, Dr. Amalia Coutsouris-Voureka, joined the Institute at St. Mary's. She was devoted to Sir Alexander, and after the death of Lady Fleming he often emerged from his loneliness in the presence of this lady. In the spring of 1953, they were married and they were to share many happy months together at home and abroad. The concluding chapter of this biography by Maurois is headed "Too Short a Happiness." On the morning of March 11, 1955, at the age of seventy-four years, Sir Alexander Fleming quietly slipped out of this world as a result of a heart attack. England hon-

ored him once again with burial in the crypt of St. Paul's Cathedral "close to the towering tombs of Wellington and Nelson."

Those individuals engaged in writing biography often have different purposes in mind. One writer tries to get at the inner man. Another author endeavors to depict the impact of an individual's work upon society. Still another writes a popular and semi-fictional biography. A biographer writing about a contemporary has the advantage over one trying to reach back over the ages and still be accurate. Unfortunately, although recently deceased, Fleming was already enshrouded in myth. Maurois has written a good biography. For me, the most exciting pages are those dealing with Wright and the early days of Fleming at St. Mary's, those describing his studies on lysozyme, and those leading up to the discovery of penicillin. The subsequent story of his travels and honors are an anti-climax, and the details of his second romance a bit superfluous.

However, we still lack a clear-cut picture of the inner man of Fleming. I had occasion to meet him several times. Professor Robert Cruickshank, Sir Alexander's successor at St. Mary's and now Professor of Microbiology at Edinburgh University, invited me to speak in 1951 at the International Congress of Clinical Pathology. I lectured at the London School of Hygiene and Tropical Medicine with Sir Alexander in the Chair. This was my first meeting with him. He asked my wife and me to dine with him at the Atheneum Club, calling for us at our hotel personally in his small English car. After that, the three of us spent the evening at the Senate House of the University of London attending a reception given by the Vice-Chancellor. Sir Alexander was the perfect host, generous and very friendly. He confided to us that he was a very lonely person since the death of his wife. My wife and I saw him again under totally different circumstances. He came to Minneapolis in the spring of 1953 with his second wife, and we entertained them in our home. He was lively and full of fun, taking a great interest in our two children. Maurois has described his love of children and how he enjoyed playing with them. After dinner he took my six-year-old son on his lap while we talked at length about penicillin. All during the conversation my son, Billy, said nothing, but at the conclusion of the discussion, he looked at Sir Alexander and said, "And now about this penicillin, I don't like the cherry taste!" Fleming laughed with delight. It is of interest to me that having met him after he had achieved fame, I found him to be a likable person, but I really didn't learn too much about science in talking with him. Perhaps he felt that his working days were behind him. Furthermore, he had been away from the laboratory bench for a long time.

Fleming now belongs to the ages, because there is little doubt in my mind that the "Fleming Myth" will persist and probably grow. One is tempted to conclude by questioning the greatness of his contribution to science. Some of his contemporaries and his own friends consider that Sir Almroth Wright was far more brilliant and original. In fact, Sir Howard Florey,[2] speaking thirteen years after he had shared the Nobel Prize with Fleming, stated "No new scientific ideas were involved in the discovery of penicillin." Sir Howard is a little severe with him.

For me, the greatness of Sir Alexander Fleming resides in two different spheres. First, Fleming was obsessed with an idea that he shared with Sir Almroth Wright. The effective antiseptic for wounds must be destructive for microbes without harming the tissues of the host. This may have been an old idea, but with this in mind he developed simple techniques for studying various antimicrobial agents. Above all, *he discovered penicillin.* Second, in this day of scientific inquiry there is a strong tendency for large sums of money to find their way into "team research." Fleming's scientific life was the opposite of this trend. He represented the individual investigator expanding his own ideas in his own way. Chain, who also shared in the Nobel Prize with Fleming and Florey is quoted by Maurois as follows: "The work of a team is important for the development of an idea already formulated, but I do not believe that a team has ever produced a new idea." Thus, the genius of Fleming, and the basis of the "Fleming Myth" are reflected in the picture of him in his small laboratory, grasping the significance of a mold that had fluttered through the air, settled on his plate of bacteria, and destroyed the staphylococcal colonies. Chance had favored the prepared mind.

COUGH REMEDIES: OLD AND NEW

Cough sedatives and expectorants have been in use for many years. Even so, treatment of cough in present-day practice leaves a great deal to be desired. Efficiency in this regard is much more than stereotype administration of time-honored drugs. It can be attained only through clear understanding of the physiology of cough, pharmacologic principles that apply to the respiratory system, and by their competent application to the individual problem.

Two types of cough are recognized: (1) productive cough; (2) unproductive cough. The terms are self-explanatory. Unproductive cough is useless and may entail adverse consequences because of the stress and strain it exerts upon the lung, heart, blood circulation, and the entire organism. Unproductive cough may originate from diseases of the paranasal sinuses, nasal obstruction, laryngeal tumor, pressure upon the trachea and bronchi by enlarged thymus, substernal goiter, enlarged lymph nodes, aneurysm or anomalous large blood vessels, mediastinal inflammation and neoplasm, large pulmonary cysts, benign and malignant tumors of the lung, bronchial granuloma and stricture. In addition to a long array of other conditions, one should underscore the causal role of pulmonary fibrosis, allergic and non-allergic bronchospasm, and pseudohypertrophic emphysema (hypertrophic, obstructive emphysema). In some of the inflammatory conditions of the bronchi (due to infections, allergens, noxious dusts, gases or tobacco smoke), there is considerable congestion and swelling of the mucosa, while formation of exudate is practically nil. This results in unproductive cough. The latter, moreover, is noted in pleurisy and in instances of reflex irritation of the vagus nerve from pathologic changes in the chest wall, diaphragm and extrathoracic structures.

Unproductive cough is harmful; therefore, it should be stopped. Slight cough may be allayed by lozenges medicated with volatile oils (menthol, thymol, eucalyptol), by swallowing a teaspoonful of honey, sweetened water, fruit juice or ice chips. Volatile oils increase mucosal secretions in the respiratory tract. Also, lozenges that contain a mild local anesthetic, such as ethyl aminobenzoate (Benzocaine) and others, are of benefit. Scratchy irritation and tickling sensation in the throat which precedes cough may be due to pharyngitis or laryngitis or to a reflex which is transmitted from the pulmonary plexus through the inferior and superior laryngeal nerves. Too, slight cough may be controlled volitionally or by teaching the patient to take a deep breath slowly, then exhale quickly and forcefully with the glottis open.

When unproductive cough becomes troublesome, hard, strenuous or exhausting, it should be suppressed with so-called cough sedatives. I have found dihydrocodeinone bitartrate superior to all other drugs in this category. It is available under proprietary names, such as Bi-Co-Tussin, Codone, Dicodid, Hycodan, Mercodinone, Paracodin, Rapacodin, Stodcodan, and in combination with other drugs. Next in efficacy are two alkaloids of opium: codeine and noscapine (narcotine, narcosine). Their dose is the same because, milligram for milligram, they are of equal therapeutic potency. It is worthwhile to remember that the analgesic action of codeine is better than that of noscapine. On the other hand, noscapine like papaverin, although an opium derivative, is not habit-forming. Rarely may it be expedient to prescribe pantopon or dilaudid.

A word of warning concerning morphine. It affects the respiratory system adversely in that it depresses the respiratory center, inhibits bronchial secretions, causes bronchospasm and thus interferes with bronchial peristalsis and bronchocatharsis. For this reason, its use as a cough remedy should be limited to patients with pain due to inoperable tumors of the lung and mediastinum or to aortic aneursysm. Also, it is permissible for patients with cardiac decompensation, excessive cough and dyspnea. Recent years have brought significant progress in this field, with the introduction of synthetic cough sedatives. These include benzonatate (Tessalon), carbetapentane citrate (Toclase), caramiphen ethanedisulphonate (Toryn) and dxtromethorphan hydrobromide (Romilar, Methorate).

Some years ago, I advocated the term "tussive

insufficiency" for designating excessive, oftentimes annoying, strenuous cough which is not capable of evacuating inflammatory exudate, transudate, extravasated blood or foreign bodies from the lung. Prompt and efficient relief of this symptom is mandatory. Auscultation of the chest is indispensable for ascertaining the presence of exudate in the bronchi and alveoli. To be proficient, one's auditory perception must accommodate to listening through the stethoscope as one's eyes accommodate to darkness before fluoroscopy.

Ammonium chloride, potassium iodide, creosotes, guaiacols, terpin hydrate, ipecac and senega are known for their capability in liquefying heavy, thick, tenacious, highly viscous mucopurulent bronchopulmonary exudate. It is useless to prescribe ammonium chloride in enteric-coated tablets. Small doses of potassium iodide are better than large doses. The potassium content of the latter may cause bronchospasm and, consequently, interfere with bronchial peristalsis and broncho-catharsis. Excessive viscosity of pulmonary exudate can be reduced by detergents, namely by the inhalation of an aqueous solution of superinone (Alevaire) and of Tergemist. Similar purpose is served by mucolytic agents, such as crystalline trypsin (Tryptar) given in solution by inhalation, or lyophilized trypsin (Parenzyme) by intramuscular injection; aerosolized pancreatic dornase (Dornavac). A combination of streptokinase and streptodornase (Varidase) in buccal tablets is also useful in this respect. I should like to point out that one of the best expectorants is inhalation of 5 per cent carbon dioxide and 95 per cent oxygen. The gas mixture is available in tanks. It is given through a face mask, with a flow rate of 5 liters per minute, for fifteen minutes three times daily for days, weeks or months, as circumstances require.

Assuming that heavy exudate in the lower air passageways has been successfully liquefied, its evacuation is substantially aided by bronchospasmolytic drugs, such as isopropylepinephrine (Isuprel, Aludrine, Norisodrine), 2.5 per cent solution of racemic epinephrine hydrochloride (Vaponephrin), phenylephrine hydrochloride (Neosynephrine hydrochloride), ephedrine and similar preparations, aminophylline, some of the anticholinergic drugs and corticosteroids.

Important adjuncts in the correction of tussive insufficiency are intermittent positive pressure breathing, exsufflation with negative pressure and portable cough machines. Particularly the latter can be used to advantage in cases with pronounced impairment of the respiratory muscles (poliomyelitis, Parkinson's disease, trauma).

In patients with pseudohypertrophic emphysema, tussive failure may be relieved by elevating the diaphragm from its abnormally low position and, consequently, restoring its function in the cough mechanism. I have been using artificial pneumoperitoneum for this purpose with gratifying results since 1930.

No matter what drug or method is prescribed for the amelioration of tussive insufficiency the following rules should be observed.

1. Hydration of the respiratory tract by increased fluid intake, "steam" inhalation or humidification of the atmosphere.
2. Postural drainage of the lung whenever necessary.
3. Weight reduction in obesity.
4. Stopping smoking.
5. Appropriate, prompt treatment of the underlying causative disease.

ANDREW L. BANYAI, M.D.

SOCIAL SERVICE

Hospital and Community Participation

All social workers at the University Hospitals are confronted with problems similar to those of the patients we are presenting today. A "Donald Matson"* of any age from any county in the state may be occupying a bed right now on Pediatrics, Neurology, Psychiatry or any one of the other medical services. This patient was chosen because his situation was a good illustration of "Community Agency Participation in Medical Care" in a variety of areas, and since this patient remained in Minneapolis, we were able to keep in touch with him for a longer period of time.

From Mr. Cremers' article, it is apparent that the social agencies in the community had done considerable planning prior to the patient's transfer from the local hospital to University Hospitals. Working in as large and as complex an institution as the University Hospitals, we often overlook this factor. Todd County is one of the twenty-three counties of the state operating on a township system of relief. This means that the township in which the person has legal residence is responsible

*The name "Donald Matson," as used throughout this editorial, is fictitious.

for providing financial assistance other than University Hospital care which is provided from county and state funds. A township is a small area six miles square, so the amount of money available for relief purposes is always limited. In counties operating on a county system, the county welfare board would have had funds, and would have provided for many of the things Donald required. As pointed out in Mr. Cremers' paper, ten out of eighteen organizations and agencies of Todd County were used for the rehabilitation of Donald Matson. Three of these remained active throughout the two-year period, maintaining interest and support. The hospital added six more social agencies to this number, actually using four. The hospital chart contains a file of eleven letters from social agencies, fourteen letters to social agencies, four physician's reports and four medical report forms. The number of individual and group conferences could not be estimated.

Briefly reviewing what happened prior to admission to the University Hospitals, Donald had suffered a fracture of the spine in an automobile accident and he had been hospitalized in a local hospital for about five months, with one unsuccessful attempt at discharge home for one week. According to the report, the attempt was unsuccessful because "in the week that he was home he was not out of his wheel chair. His parents were afraid that they would hurt him and, as the mother explained, 'we had no bed for him.'" The community hoped that in addition to medical care he could be taught to care for himself and that some consideration would be given to a vocational program. It was assumed that the patient would finish high school upon his return home, and a suggestion of a job in the local printing establishment was offered as a possible vocational placement.

The medical report presented by Dr. Sandler shows that on Donald's arrival at University Hospitals he was found to be paralyzed from the waist down; he had a large sacral decubitus, an incompletely healed fracture of the right tibia and fibula, a urinary tract infection, and urinary and fecal incontinence.

When I first saw this seventeen-year-old boy, he was lying on his side in bed listening to a ball game on the radio. His conversation about the players indicated that he was an ardent, well-informed baseball fan. He was a good-looking, dark-eyed, curly-haired boy of medium build. He was friendly, and spoke freely about his accident, the attention he had received in the community, and about his family. He showed me some kodak pictures he had in his billfold and letters he had received. The subject of school was brought up, and he said that his accident had happened about six weeks before the end of the year and he thought he was "passed." He thought he should find out and accepted the suggestion that I write to the school so that we might continue the school program in the hospital.

The school report was disappointing. He scored D and F in all subjects except industrial arts in which he got C's. His behavior traits as recorded by his teachers showed that in initiative and industry he needed constant prodding, he lacked ability in judgment and common-sense and his reliability was inaccurate. He was well liked in senior high school but was tolerated in junior high school. There was nothing to indicate that he had been "passed."

During the following months between surgical and medical procedures, the patient was given a number of psychological tests. The Minnesota Multiphasic Personality Inventory indicated that he was somewhat tense, irritable, and pessimistic and that one might anticipate such signs of psychological distress as easy fatiguability, feelings of inferiority, inadequancy, and depression. The Wechsler-Bellevue Intelligence Scale gave a full scale I.Q. of 107, a verbal scale of 101 and performance scale of 111. A summary of the tests showed him to have average learning ability, masculine interests with poor achievement in academic areas.

Representatives from the State Division of Vocational Rehabilitation were invited to the hospital to discuss Donald's future vocational program. At this time, it was felt that the most feasible occupational goal would be a linotype operator. This occupation was selected because there was a job available in the community, it was a sedentary occupation well suited for a paraplegic, and it would not require extensive education and training. His deficiencies in grammar and spelling coud be overcome by remedial work in prevocational classes. Although the patient appeared to be somewhat indifferent to the training program, he seemed quite willing to accept the occupation of a linotype operator, probably because of the mechanical nature of the job. The plan was agreed upon, and the vocational

rehabilitation counselor was to contact the local publishing company to make certain a job would be available to him. The patient was started on prevocational classes. At this point, the patient's decubitus was healing satisfactorily, his braces had been delivered and a special wheel chair had been ordered and payment approved by the local community.

A visit to the hospital at this time by the chief of police, who was also the village recorder gave additional social information. The chief of police had been in to see the patient a few times and he felt he was doing very well. He recommended keeping the patient at University Hospitals until he had reached his maximum benefit because he would get no help at home. He said that the father, who is a janitor at the printing company and somewhat dull, had never been able to do very well for the family; the mother is a poor housekeeper, but she had never had much to do with, and the home was about as bad as some of the "out-buildings" on his farm. He said that the patient's twin brother is very wild and a complete failure in school. He had been involved with the law. He praised the fourteen-year-old sister and the younger boys, aged eleven and nine years. He was interested in the vocational plan, but was doubtful that there would be a job in the local print shop because the typesetters had to do their own lifting and carrying.

The patient's progress in prevocational training was average for the first month and then he gradually began to deteriorate. Counselling interviews and interviews by the doctors and social worker were not effective in motivating him. He became more negative, pessimistic, uncooperative, and apathetic. He finally frankly admitted that he was not interested in vocational training and when he was ready to leave the hospital he "just wanted to go home and be a mink trapper."

Another conference of the medical staff, the vocational counselor, the social worker, representatives from the State Division of Vocational Rehabilitation, and from the State Division of Employment Service was held to review the original vocational plan and explore other possibilities. The alternatives suggested were (1) that the patient return to his local community, complete his two years of high school and then consider a vocation, (2) that an attempt be made at direct job placement in an unskilled job where he could be trained on the job. The state vocational counselor was to visit the local community to see what the physical arrangements were at the school, and the state employment worker agreed to try to find a suitable job. In addition, a referral was made to the Minnesota Jewish Vocational Service for help in job placement in Minneapolis.

The patient rejected the idea of returning to school and said he would be truant more than he would attend. He accepted the idea of job placement in Minneapolis, saying that he could get his twin brother or one of his friends to come to live with him. The staff decided to start the patient on a work evaluation program in prevocational training to determine the patient's endurance in a work situation, the length of time he could stand before he became fatigued, and what adaptations would be needed for job performance.

When Donald had completed his medical treatment, he was transferred to a boarding home to continue his prevocational evaluation on an outpatient basis. He went to live in one of the boarding homes used by the hospital, but soon these facilities were found to be inadequate to meet his hygienic needs. He developed an infection, was rehospitalized and at discharge was placed in a nursing home, the expense for both placements authorized by the village council. At this point, the patient was able to walk with long leg braces and crutches on a level surface, and he was able to get up and down stairs with railings. He lacked the body control and confidence to swing on and off street cars or buses or up and down curbs.

The vocational counselor of the Department of Physical Medicine secured a job for him as a contact lens technician for a Minneapolis Optical Company with training on the job at company expense. Donald and a friend, a poliomyelitis victim in a wheel chair and a former hospital patient, found a hotel apartment suitable for their physical needs where they could do their own cooking and laundry by themselves without assistance.

In assisting Donald to make the transition successfully from the security of the protected hospital environment, where he had lived for almost two years, to the insecurity of independent living, several things had to be taken into consideration: (1) supervision in the maintenance of physical health, (2) helping him to perform satisfactorily on the job and to handle his anxieties about meeting new people, (3) helping him to adjust to a new way of living as a severely handicapped person,

(4) assisting him to learn to take care of himself from every standpoint, (5) helping him to secure financial assistance. The doctor, the vocational counselor, and the social worker each contributed in his particular area, with many areas overlapping.

Adjustment to a new way of living, facilitating medical care, and obtaining financial assistance are primarily the concern of the social worker. As a first concrete step, the services of a student dietitian were secured to help Donald and his roommate with food and housekeeping problems.

Assisting with the financial matters was a difficult problem in that the apartment rent had to be paid in advance and the costs of living, including taxi-fare to and from work, met on a current basis. An Aid-to-Disabled grant had been applied for in advance from Todd County and a tenative budget submitted showing the deficit between the cost of living and Donald's earnings. However, no definite action could be taken until the regular board meeting, although verbal committment had been made. This left a gap of about two weeks during which Donald had to finance himself which he could do only by borrowing. His anxieties mounted and he became greatly discouraged. It was necessary to give him much support and encouragement to continue to remain in the city and at his job. In order to provide more adequately, the Todd County Welfare Board requested the Hennepin County Welfare Board to supervise Donald's financial needs and to provide the services that agency could offer to him.

This presentation has been focused primarily on the inter-relationship of the hospital and the community agencies in carrying through a rehabilitation plan for one patient. There is much that could be said about the work of the hospital team with this patient and his social problems in the rehabilitation process.

Much explanation of the staff plan, the prognosis for the patient with and without complete rehabilitation, and the value of timely help was necessary to obtain the assistance from the agencies when it was needed. Although the community agencies wanted rehabilitation for Donald, the expense was hard to accept, particularly the amount needed from the township to supplement his salary.

Donald had a relatively low estimate of himself and his abilities and had little encouragement and help from home. He was a young person, a school boy, who had carried little personal responsibility. He required much help in developing confidence in himself and assuming responsibility for his own planning.

He was easily discouraged with the many obstacles to his progress. Continued support from all members of the rehabilitation team was given to help him carry through in the most difficult and challenging phase of his life.

It is to be anticipated that Donald will continue to have medical problems and problems of growth and adjustment for which the hospital as the medical agency must assume leadership if the goal of restoring to maximum capacity, physically, psychologically, and economically is to be reached.

We have presented the case of Donald Matson to illustrate the need for the assistance of community organization and agencies in the completion of medical treatment plans for people.

CLAIRE E. CENSKY

CANCER OF THE LUNG

Primary cancer of the lung has increased so rapidly that it has now assumed epidemic proportions. Despite the raging controversies in the press, newspapers and scientific journals, the cause of bronchogenic carcinoma still remains unknown. Factors that may be of some importance in the cause of bronchogenic carcinoma are still matters of dispute and no single or multiple factors have been documented as being the cause of primary carcinoma of the lung. This type of carcinoma has no specific or characteristic symptoms. In fact, when symptoms appear, the lesion is often inoperable. Despite early diagnosis and early surgical treatment, the disease still remains difficult to cure or to control. It is well established that most patients with bronchogenic carcinoma are seen by the surgeon too late for any curative procedure to be performed and only palliation may be offered. This unfortunate event is the failure to be constantly cognizant that carcinoma of the lung will, does and can mimic many other intrapulmonary lesions. It can mimic anything from the solitary nodule to tuberculosis. One should be constantly aware of any pulmonary lesion, allowing that it may represent carcinoma. If the lesion fails to follow the clinical course suggested by the original diagnosis, one should institute immediately procedures that would establish the diagnosis as

to whether or not the lesion is malignant. Delay in instituting diagnostic procedures results in the lesion becoming inoperable. It may be stated that any chest lesion is a carcinoma until it is proven otherwise. The constant high index of suspicion that malignancy exists in any lesion in the chest will lead to the early diagnosis of the malignant lesion. In those lesions in which diagnosis cannot be resolved within a short period of time, exploratory thoracotomy is indicated to establish the diagnosis. It should be recognized that there is morbidity with exploratory thoracotomy, but it carries a low mortality rate. It should hold the same position in obscure diseases of the chest as does an exploration in obscure diseases of the abdomen.

In the event that the patient has a solitary nodule or coin lesion, there is only one way to establish the diagnosis and that is by histological study of the removed lesion. It has been well stated that a lump in the lung, like a lump in the breast, is diagnosed only by the pathologist, and the early diagnosis of such a cancer will best be done by remembering its great power of mimicry.

J.F.B.

AMA TO HOLD THIRTEENTH CLINICAL MEETING IN DALLAS

The American Medical Association's thirteenth clinical meeting December 1-4 in Dallas, Texas, will draw some 3,500 physicians, mainly from the southern and southwestern states.

Planned in co-operation with Dallas physicians, the meeting is designed to help the family physician meet his daily practice problems.

Dr. Everett C. Fox, Dallas, is general chairman of the meeting, while Dr. C. D. Bussey, Dallas, is program chairman.

Among the subjects to be discussed on the scientific program are soft tissue injury; whiplash injuries of the neck; diabetes; heart murmurs in children; new laboratory procedures; new resuscitation techniques; premarital and marital counseling, and the problem child.

Dr. Hubertus Strughold, professor of space medicine at the School of Aviation Medicine, Randolph Air Force Base, Texas, will be principal speaker at the opening scientific session December 1. Dr. Strughold, often called "the father of space medicine," will discuss the role of medicine in the space age.

The winner of the AMA's Distinguished Service Award at the Atlantic City meeting—Dr. Michael E. DeBakey—will participate in a symposium on the surgical considerations of cerebrovascular insufficiency Tuesday afternoon, December 1. Dr. DeBakey, chairman of the department of surgery at Baylor University College of Medicine, Houston, was given the award for his outstanding contributions to medicine in the field of vascular surgery.

The scientific program, including lectures, symposiums, medical motion pictures, color television, and nearly one hundred scientific exhibits, will be held in Dallas Memorial Auditorium. Industrial exhibits will number 251.

The auditorium will also house the "world's largest health fair," sponsored by the Dallas County Medical Society in conjunction with the AMA. The fair will run from November 27 to December 7 and will be open to the public.

The fair will feature 150 educational exhibits, prepared by the AMA, allied health groups and voluntary health organizations. They will be manned by members of the Dallas society.

Another special feature of the AMA meeting will be a national conference on the medical aspects of sports, to be Monday, November 30—the day before the AMA meeting opens.

The conference, to be held under the auspices of the AMA's Committee on the Medical Aspects of Sports (formerly the Committee on Injury in Sports) will be open to athletic directors, coaches, and trainers, as well as interested physicians.

The program will cover the general areas of the physiology and pharmacology of exercise, the training and conditioning of the athlete, and the prevention and treatment of injuries.

This is the second time that the AMA has met in Dallas. It held an annual meeting there in 1926. One AMA president has come from Dallas—the late Dr. Edward H. Cary, who was inaugurated in 1932 at the New Orleans meeting.

The AMA House of Delegates, numbering 208, will meet throughout the week at the Adolphus Hotel, meeting headquarters. The first act of the House will be to name the General Practitioner of the Year. The late Dr. Lonnie Coffin, Farmington, Iowa, was the last recipient of the award, given annually to an outstanding American doctor for his medical and civic contributions to his community.

The first recipient of the award was Dr. Archer Chester Sudan, Kremmling, Colorado, who received the award at the first clinical meeting in January 1948 at Cleveland.

The clinical session has been held in St. Louis, Washington, D. C., Los Angeles, Denver, Miami, Boston, Seattle, Philadelphia, and Minneapolis. Physician attendance has ranged from 1,896 at the first Cleveland meeting to 4,427 in Boston.

Eye-catching displays and the activity of glaucoma screening tests attracted large crowds of state fair goers at the Minnesota State Medical Association booth. An estimated 10,000 persons stopped at the booth to receive glaucoma and general health information literature and discuss health problems with attending ophthalmologists and staff personnel.

At the 1959 State Fair

Ophthalmologists Give Glaucoma Screening Tests

A total of 2,950 persons who attended the 1959 Minnesota State Fair received glaucoma screening tests in the Minnesota State Medical Association booth. Activities for this year's project were coordinated by members of the Committee on Ophthalmology; Dr. Robert W. Hollenhorst, Rochester Chairman.

Forty-five possible cases of glaucoma were diagnosed by fifty-seven ophthalmologists, including sixteen residents who co-operated in the project. Fifty-three student nurses from Twin City hospitals and two resident nurses assisted in administering the tests.

The Minnesota State Medical Association booth, a permanent structure, is located at the crossroads in the Education Building on the Minnesota State Fair grounds. The booth was constructed in 1956 at a estimated cost of $1,000.

In 1956, the Committee on Ophthalmology featured a glaucoma display. At that time, state ophthalmologists were present to answer eye care questions asked by the State Fair goers, and glaucoma information literature was distributed.

The following year, the Committee on Conservation of Hearing administered audiometer tests. Sound-proof booths were used and an average of one test every five minutes was given, twelve hours each day for the ten-day event.

Polio shots were given to an estimated 5,000 persons between the ages of twenty-one and forty who attended the 1958 Fair. This project was coordinated by the Committee on General Practice.

The Committee on Public Health Education would like to receive suggestions for a project to be used at the 1960 State Fair.

TONOMETER TESTS were given by participating ophthalmologists who worked in teams of two for a four-hour period. Equipment available at the booth for giving preliminary glaucoma screening tests included tonometers, slit lamps, and chairs. Dr. John L. Bonner, Minneapolis, resident ophthalmologist, is shown giving the eye-pressure test to one of the 2,950 persons who received the tests.

President's Letter

HOW HIGH IS THE COST OF MEDICAL CARE?

The high cost of medical care has been the basis for countless newspaper and magazine articles. The mere mention of "high costs of medical care" will insure readership to an editor. Likewise, the commentator who discusses this subject on radio or television, has a guarantee of a sizeable audience.

Just how high is the cost of medical care? The Bureau of Labor Statistics' figures compared with 1939, show that the twenty year increase for medical care is 106.09 per cent, or one and 99/100 per cent lower than the 108.08 per cent figure for all items. For the same period, food costs rose 149.09 per cent.

What about the cost of non-professional services and commodities? Recently I've found myself paying eighty-five dollars to a television repairman for a new picture tube and installation charges in order to be able to watch the World Series. The Real Estate tax on my home has risen nearly 300 per cent in the past twenty years; the cost of painting the exterior of my house has risen 250 per cent in the past fifteen years.

Everybody knows the cost of a plumber's house call to open a plugged drain. I can't dismiss the $39.50 per year heating service contract. This is exclusive of repair parts. The time spent by a serviceman is less than two hours. Depreciated equipment at the office or the hospital must be replaced. Every physician knows the cost of replacing instruments and examination tables at current prices.

We have been told that in 1933, the man-hours of work needed to pay for a visit to the average doctor's office were four hours and forty-eight minutes. Today it takes only one hour and forty-two minutes of labor to pay for that same visit.

A doctor's house call in 1933 required an average of seven hours and forty minutes wages to pay for that service. Today, the equivalent of two hours and forty-eight minutes is required.

In 1930, the cost of routing a case of pneumonia was $1,000. Today, antibiotics totalling $25 will do the same job.

In 1949, one mg. of vitamin B-12 cost $20. Now its cost is compared to a twenty-five cent bag of jelly beans. A dose of 100,000 units of penicillin cost about $20 in 1943. Since that time, this same wonder drug has decreased in price to approximately seven cents per million units for sterile forms. Today, streptomyocin which cost about $30 per gram in 1945, costs manufacturers eight and one-half cents per gram.

In 1949, there was a price tag of $200 for a gram of cortisone. Today a day's supply of cortisone can be purchased for less than the price of a package of cigarettes.

Many of the diseases which once were "killers" are today's minor illnesses.

Perhaps there is a need for re-evaluation in a generation when Americans are enjoying the greatest economic boom in history. Wages, salaries, dividends, investments and interest rates are ever reaching new plateaus. People are going places and doing things. The upward trend in home-building and remodeling is another evidence of the public's confidence in the economic future of America.

What about the economics of the nation's health? It would appear that we, as the medical profession, have an important public health education job to perform. We must show the public how little good health really costs.

Sincerely,

Benjamin B. Foulston M.D.

George Earl, M.D., Chairman

ADMINISTRATION EXPRESSES STAND ON FORAND BILL

One of the significant results of the recent House Ways and Means Committee Hearings on the Forand Bill was the stating of the administration's position on H.R. 4700. At that time, Secretary of Health, Education and Welfare, Arthur S. Flemming, the first witness at the hearings, made clear the administration's postion, which, until that time, had not been known.

Secretary Flemming summarized the administration's position in these words.

"*We must come to grips* with the problem of providing adequate hospital care for the aged.

"The percentage of aged persons covered by *hospital insurance* written by non-profit groups and insurance companies has increased in a very significant manner in recent years.

"There is every indication that the percentage of aged persons covered by hospital insurance written by non-profit groups and insurance companies *will continue to increase.*

"The enactment of a compulsory hospital insurance law would represent *an irreversible decision* to abandon voluntary insurance for the aged in the hospital field and would probably mark the beginning of the end of voluntary insurance for the aged in the health field generally.

"Instead of abandoning voluntary hospital insurance for the aged in favor of compulsory insurance, every possible effort should be made to determine whether or not a plan can be developed that will *strengthen the voluntary approach* by making adequate protection available to a larger percentage of the aged."

No action is expected on H.R. 4700 during the remainder of this Congressional session.

MD OFFERS FORAND "PRESCRIPTION"

Physicians are devising new ways to help congressmen reach decisions concerning H.R. 4700, reports *MD* (Medical Legislative Digest), published by the Council on Legislative Activities of the American Medical Association.

According to the report, Doctor Charles G. Smith of Arlington, Virginia, sent the following message to members of Congress on his regular printed prescription blanks.

"If you feel a temptation to vote for the Forand Bill, please call me at once (any hour of the day or night) and I'll be glad to come and sit with you until you feel better."

MD points out that one Congressman, Representative Wright (12th District of Texas) not only called it "One of the cleverest things I've seen along this line" but he had also promised to oppose the bill.

KEOGH-SIMPSON HEARINGS END

Senate Finance Committee Hearings on the Keogh-Simpson Bill, H.R. 10, concluded on August 11.

Twelve witnesses testified on the first day of hearings in support of the bill. Senator Moss (D. Utah), the first person to testify, pointed out that it was imperative that the measure should be enacted during the 86th Congress. Support was given to the measure by a representative of the National Live Stock Tax Committee who pointed out that he was disturbed to find that the bill had been criticized as being sponsored only by doctors, lawyers and a small group of businessmen. He could not understand why farmers and ranchers had not been included as sponsors of the bill since they represented one of the largest groups of self-employed and have been on record as approving the bill for some time.

Congressman Keogh, co-sponsor of the bill, was the last witness to appear before the Committee. He argued against a proposed amendment which would force a self-employed individual to set up a plan for his employes in order to take advantage of the self-retirement plan.

NEW DEFINITION OF DISABILITY HEARING ASKED

Senator Estes Kefauver (D., Tenn.) has introduced S. 2459 which would amend the Social Security Act to preserve the insurance right of individuals who, because of disability have lost at least sixty per cent of their earning capacity.

Under present law, disability is defined as the inability of an individual to engage in any substantial gainful activity by reason of any medically determinable physical or mental impairment which

can be expected to result in death or to be long-continued and of indefinite duration. This bill would expand the definition to include an individual who has lost at least sixty per cent of his earning capacity because of a physical or mental impairment.

SENATOR MORSE ATTACKS ORGANIZED MEDICINE

One of organized medicine's severest critics and Senate sponsor of the Forand Bill, has been at it again.

In one of his latest Senate floor speeches, Oregon's Democrat Senator Wayne Morse has challenged the AMA to try to defeat him. In the opening remarks of his speech, Senator Morse named the AMA as the "chief lobbyist" against his bill. He also accused the AMA of using "false propaganda" to defeat the Forand Bill. He branded as "poppycock" any fear that providing medical care to the aged through the social security system would lead to socialized medicine.

Following are the pro-Forand Bill remarks of Senator Morse's speech delivered August 6, 1959.

"Let me say to the doctors of America, I am not worried about any danger of socialism in American medicine, but I will tell the doctors of America what I am worried about. I am worried about undue commercialization in American medicine.

"I care not what the political effects may be on the senior Senator from Oregon as a result of these remarks. If the doctors think they can defeat me, I ask them to come to Oregon and try. They are going to discover that the people are with me.

"Increasing millions of people in America are going to be with those of us who recognize the great moral obligation to the aged of this country as the years go by. We must take away from the doctors of America the right to tax, which they now exercise. They exercise it under the guise that they think they should be allowed the right to impose certain fees upon those who they think are better able to pay higher medical fees, in order to take care of the medical cost to patients the doctors serve who cannot pay such fees.

"That principle being followed by the medical profession in America has no place in America. I deny that the Government should tolerate the kind of medical fee tax policy practiced by the American medical profession. The American medical profession should charge reasonable fees—and I want them to have reasonable fees. They will find that no Member of this body can be counted upon more certainly to protect the right to the private practice of medicine than the Senator from Oregon. There is not a syllable in my bill that infringes upon the right of doctors to engage in the private practice of medicine free of any threat of socialized medicine. What my bill proposes is to see to it that the aged people have the wherewithal to pay the private doctor of their own selection to treat them in their declining years. That is not socialism. That happens to be putting to work the great religious principles that we profess, but, too frequently, I am afraid, do not practice.

"There is house-top after house-top, by the thousands in our country today, covering the heads of millions of old people over sixty-five, who are living under the gnawing fear that a serious illness will wipe out such little earnings as they have been able to save, and impose a tremendous financial burden upon their children or other relatives to take care of them in years of illness.

"I happen to believe that the time has come to face up to this issue in America, and proceed to recognize that there is a responsibility on the part of the people of the Nation as a whole to provide legislation which is necessary, such as the bill I propose, to pay for the expenses of such illness through social security. There is needed legislation which will make it clear to the medical profession that we will protect them in the right to the private practice of medicine and at the same time protect the American people from undue commercialism in medical costs.

"I think we should draft a bill along the lines of the bill I am now offering, which leaves no room for doubt that we are protecting the private practice of medicine, but also makes it perfectly clear that we have the responsibility to enact legislation which will assure the aged in this country that they do not have to look forward to the declining years of their life under a gnawing fear that they will not be able to get the medical attention they need.

"Although reactionary doctors will not approve nevertheless I take the position—and let us take the issue to the crossroads of America—that the medical profession does not have the moral right to charge whatever fees it chooses to charge. On the contrary, the Government has the duty to impose restrictions upon the medical profession similar to the restrictions we have imposed upon other economic groups whenever an economic group takes advantage of the people.

"In my judgment we must face up to the question of medical costs. I have been at work for months in preparation for the hearings to be conducted by my subcommittee of the Committee on the District of Columbia, in regard to medical costs in the District of Columbia. I had hoped, and I still hope, that we may be ready for those hearings before Congress adjourns this month. But if we are not, we will proceed with them this fall, or at the beginning of the next session of Congress.

"I believe that the doctors themselves are drawing this issue. I am for meeting the issue, and for placing in effect Government regulations necessary to give to the people of the country the protection which I have come to believe they are entitled to, from excessive medical costs and hospital costs."

DOCTOR LARSON ADDRESSES GROUP HEALTH ASSOCIATION OF AMERICA CONFERENCE

Dr. Leonard Larson, Chairman of the American Medical Association's Board of Trustees and Chairman of the Council on Medical Care Plans, was a participant in the recent Group Health Association of America Institute held in New York City.

The occasion marked the first meeting of Group Health Association of America, an organization formed as the result of the merger of the American Labor Health Association and the Group Health Federation of America.

The GHAA publication commented "for the first time in the history of the GHAA Institute, an official of the American Medical Association participated, marking a new line of communication with organized medicine."

Doctor Larson described the AMA's "continuing battle for the improvement of the quality of medical care." He pointed out that AMA's contribu tions include "standards it has approved and urged in medical education, hospital accreditation, licensure, and specialty training." Doctor Larson also cited the grievance and third-party liaison committees organized by many medical societies to handle over-charge complaints and assure quality of medical care.

He brought to the attention of delegates, the new AMA Medical Disciplinary Committee whose purpose is to "uncover areas where disciplinary measures against 'poor practitioners' may be most needed." The AMA spokesman emphasized that the patients' reaction to the type of care he receives is important in measuring quality of care. According to Doctor Larson, "a patient may receive a maximum of benefits medically or surgically, but still feel psychologically that he has not been helped. The doctor is concerned with more than a patient's physical needs, but he also must be concerned with emotional and psychological aspects of the individual as they relate to, or have an effect upon, illness or disability."

Union and Closed Panel Groups Review Medical Care Plans.—Delegates attending the first Institute sponsored by Group Health Association of America in New York City, heard representatives of labor, lay sponsored group health care plans, and government, present their views regarding medical care plans.

Humphrey Speaks.—Senator Hubert Humphrey (D., Minn.) was introduced by Mrs. Eleanor Roosevelt as a GHAA Institute luncheon speaker.

According to the *GHAA Newsletter,* Senator Humphrey called for legislation to provide hospital and nursing home care to aged persons through social security. He further pointed out to the group that aged people will still need a total health program "to keep them *out* of the hospital and functioning in their home and in the community." Senator Humphrey also told the luncheon audience that legislation should encourage voluntary action in experiment with medical care organization and financing. He described a bill which he introduced in Congress to provide long-term loans for the establishment of group practice facilities for voluntary non-profit pre-paid health plans.

Dollars and Medical Care.—AFL-CIO Secretary-Treasurer, William F. Schnitzler, one of a broad range of speakers which GHAA Delegates heard, stated "doubling the premium does not double the financial protection, and doubling, tripling, or quadrupling the premium may very well do nothing at all to improve the kind of medical care that people get. The vast bulk of medical expenses remain uncovered."

According to the GHAA summary of Mr. Schnitzler's remarks, organized labor will continue to co-operate with established health insurance plans, but "will work increasingly in the future directly with physicians and hospitals" to achieve comprehensive medical care plans. Mr. Schnitzler also demanded the elimination of economic barriers for members seeking needed medical care.

"State legislation that restricts the free development of responsible attempts by people to organize together to meet their medical needs must be wiped off the books," said Mr. Schnitzler. "There is no justification for the continued existence of barriers to the establishment and growth of all but a few specified kinds of prepayment plans."

He also called for "unfettered experimentation and exploration" to develop organizations that can provide high quality medical care at a reasonable cost.

Cars that did not have the right of way injured 608,400 and killed 3,890 persons on U. S. Highways in 1958.

Public Health

BIOLOGICS FOR IMMUNIZATION DISTRIBUTION POLICY DESCRIBED

In order to provide immunizing materials to accomplish the most widespread coverage within available appropriations the State Board of Health has set up the following policy.

Biologics for immunization distributed by the Minnesota Department of Health are primarily intended for use in school and community immunization programs organized in co-operation with the local medical society. Immunizing materials for these programs will be supplied to physicians as in the past within the limits of available supplies. Such materials will also be supplied to physicians for private patients who cannot afford to pay for the vaccine. Since the vaccine is supplied without charge to the physician no charge to the patient shall be made for the material. The physician, however, is entitled to make a modest charge for the service.

Immunizing materials for state institutions including educational institutions will no longer be supplied from this department since these institutions are eligible to purchase vaccine at the same favorable prices as this department. State agency purchases should be made through the Division of Procurement, Department of Administration, State of Minnesota (Annual biological price agreement covering period July 1, 1959 to June 30, 1960). The State Board of Health strongly recommends that such institutions in no way curtail their immunization programs.

Old Tuberculin for Mantoux testing will be supplied on request as in the past. Gamma globulin for prevention and modification of measles and for the prevention of infectious hepatitis in household contacts will be supplied as in the past as supplies permit. Gamma globulin is supplied free of charge by the American Red Cross on an allocation basis to the various states. No charge should be made for this material, but a service charge may be made for administration.

Biologics distributed by the Minnesota Department of health for immunization and/or treatment include:

Diphtheria
Antitoxin* (in vials of 1,000; 10,000; 20,000 units)
Diphtheria antitoxin also available from antitoxin stations maintained in all parts of the state
Diphtheria-Tetanus toxoid, A.P. (Pediatric)
Diphtheria-Tetanus toxoid, A.P. (Adult)
Diphtheria-Tetanus toxoid, A.P. with Pertussis Vaccine (triple antigen)
Schick test material (limited supply)

Infectious hepatitis
Immune serum (Gamma) globulin* (for household contacts only)

Measles (Red measles only)
Immune serum (Gamma) globulin* (for modification or prevention of measles in children four years of age and under. *Not* furnished for pregnant women exposed to German measles)

Pertussis
Hyperimmune serum* (for treatment of sick children under eighteen months of age)
Diptheria-Tetanus toxoid, A.P. with Pertussis vaccine (triple antigen)
Pertussis vaccine, A.P.

Rabies
Antirabies serum* (for emergency use in severe bites of head and neck in conjunction with antirabic vaccine. Antirabic vaccine is not supplied but is available commercially)

Smallpox
Smallpox vaccine

Tetanus
Tetanus toxoid, A.P.

Tuberculosis
Tuberclulin (dilutions 1:100, 1:1,000, 1:10,000)

Typhoid Fever
Triple typhoid vaccine

*Limited supply and outdating of biologics permits distribution only for immediate use.

LEVELS OF STRONTIUM 90 IN WATER COURSES

The Public Health Service reported today on the levels of strontium-90 in the Nation's major water courses.

The figures, based on weekly samples from fifty-one stations, are very substantially below the levels which the National Committee on Radiation Protection and Measurements considers permissible for life-time exposure by the general population.

Based on weekly samples from the stations, the data are part of the information being gathered on stream pollution by the national water quality network operated by the Public Health Service. The network includes seventeen major rivers.

The study will eventually provide precise measurements of all important forms of pollution in the Nation's water resources, including the presence of plankton, and the general chemical, physical and bacteriological characteristics of major rivers and streams.

The water quality network, operated in co-operation with State and local governments, universities, and industry, was established in 1956 on recommendation of the President's Advisory Committee on Water Resources Policy. The present 51-station network is expected to increase to 75 during the coming year and will eventually include 250 stations.—U. S. Department of Health, Education, and Welfare, Public Health Service, Washington 25, D. C.

The Art of Medicine

GOVERNMENT MEDICINE—A "FREE" RIDE?

Three different views on governmental control of medicine were presented at the Thursday morning session, "Buy Your Own Ticket—or Get a 'Free' Ride?"

A German, a Canadian and an American summarized the dangers of socialized medicine on the basis of their individual backgrounds.

The speakers were Rolf Schlogell, M.D., of Cologne, Germany, Secretary-General of the Organization of German Doctors Engaged in Health Insurance; B. E. Freamo, Toronto, Assistant Secretary (Economics), Canadian Medical Association, and Claude Robinson, Ph.D., Princeton, N. J., Chairman of the Board, Opinion Research Corporation.

Doctor Percy Hopkins, Chicago, a member of the AMA Board of Trustees, moderated the discussion.

Already Too Resigned?

Doctor Schlogell warned that "We have already resigned ourselves in too great a degree to our fate by complying with the complicated machinery of today's social life in surrendering our individual freedoms in order to guarantee a frictionless living together as a whole.

"Already many of us," he continued, "have in this way lost the ability to judge whether or not the abandonment of rights and freedoms is worth the personal price we pay."

The German pathologist devoted most of his remarks to a critical analysis of governmental health services, which he defined as "an institution that grants protection against disease to every citizen of the country, financed . . . from the state budget."

Government Can't Be Neutral in Health Field

Because of the state's position in the health insurance of a nation, Doctor Schlogell said, "it automatically loses its neutral position as a mediator between the groups or between individuals."

Under government health systems, he pointed out, "four freedoms are restricted:

"1. The freedom of the patient to choose the doctor in whom he has confidence.

"2. The freedom of the doctor to refuse further treatment to the patient if the confidence each has in the other—the psychological basis in the healing of illness—is destroyed.

"3. The freedom of the doctor to practice his profession according to the rules of medical art and science—free to select the suitable techniques in diagnosis and therapy and to reject those that are unnecessary or even detrimental.

"4. The freedom of supervision of the doctor by professionally qualified groups—free from the authoritative influence of laymen."

Mr. Freamo described the attitudes of Canadian physicians to government medical control by the phrase, "It can't happen here."

During the past two years, however, "we have had to face reality: it can happen here," he said.

"Governments have become more fiscally irresponsible," he continued. "They no longer hesitate to implement a program just because we can't afford it. These

reasons suggest the possibility that governments might, for reasons of political opportunism alone, implement a program of medical care insurance."

In Canada, he said, a system of federal government support of hospitals has won "widescale public approval." Although the Canadian Hospital Association "has gone on record as approving the plan," Freamo noted that "the attitude of the medical profession varies widely."

Medicine Must Keep Abreast of the Times

He urged against anything which might deteriorate the quality of medical care or interfere with medical progress.

"I cannot foresee that the art of medicine can possibly be enhanced under the conditions which must eventually be associated with government control. Further progress in the quality of medical care is not consistent with a program which must stress equality of care."

Doctor Robinson said that since "change is the order of the day" in American society, the medical profession "should anticipate change and lead it."

"The status-quo is yielding everywhere," he observed.

Medical Services Must Be Improved

The immediate goals of both medical societies and individual physician, in Doctor Robinson's opinion, should be "to improve services and cut down on complaints.

"Study the needs of the people—then meet them," he urged.

"Every doctor must understand the public view as well as his own view."

He suggested that physicians look on the struggle against socialism as basically "a merchandising problem."

Study Needs of the People

"The key to successful selling is to study the needs of the people, show how your product is better than the competition's, and get your product before the people.

"Your product is medical leadership—the doctor-patient relationship."

Government is Medicine's Number One Competitor

He warned that "The competition in the medical marketplace today is offering an attractive bill of goods."

The principle competitor, the federal government, was described by Doctor Robinson as "a clever competitor—one that says it will give the people something for nothing."

He pointed out that the government already has prepared "a health package for the veterans, a package for the old people. If they are successful with the old people, then they will have packages for infants, teenagers, newly-marrieds, then complete socialization of health care."

The government, he said, "is emphasizing the positive approach and is using what we call the 'Hard Sell' on the public."

OFFER HEALTH MATERIALS TO PTA GROUPS

Is there a PTA or some other community organization which could use health information material? Why not contact these organizations in your community to see if you or your county medical society could extend this service.

Your state office has adequate supplies of many AMA health education materials on hand. Others can be ordered if required.

Materials available include: "What Everyone Should Know About Doctors"; "Health Services School-Age Children Need"; "The Best Defense Against Sex Perverts"; "Let 'Em Eat Hay"; "Personal Health Information Record"; "Beware of the Healer who Guarantees a Cure, He May be a . . . 'Quack' "; "The Merchants of Menace"; "To All My Patients"; "The Healthy Way to Weigh Less"; and "Your Family Health Record".

Samples of these will be sent upon request.

History of Medicine in Minnesota

PIONEER PHYSICIANS OF STEVENS COUNTY, MINNESOTA

JOSEPHINE EDDY, GRACE HALL
A. I. ARNESON, M.D.
Morris, Minnesota

ROBERT ROSENTHAL
Saint Paul, Minnesota

Stevens County was established by an act of the legislature on February 20, 1862, and was named in honor of Isaac I. Stevens who headed a commission in the late "fifties" for the survey of a line of railroad from Minnesota to the Pacific Coast. An old trail from the Selkirk Red River settlements to the Mississippi River posts passed through this area. Before that, it had been a favorite hunting ground of Indians. There is no record of any settlements before the Indian Massacre of 1862 which stopped all travel and immigration.

An Indian scare came in 1868 when the Sioux and Chippewas were in conflict. Near the Lake Crissey Park the Sioux killed one of their own squaws who had married a Chippewa. A battle was fought and a number of Indians were killed and buried near there. Governor Austin sent out military supplies: Stevens County was assigned to Company H, First Regiment, with John Folsum as Captain. It was later used by soldiers on frontier duty who used it as a camping ground. When peace was established, travel was resumed by stage lines on the trails, and some of the soldiers returned as settlers.

Gager's Station was made a stopping place, trading post and, later, the temporary county seat. On the trail of the Minnesota Stage Company, and built in 1866, it consisted of a boarding house and sleeping quarters for travelers, barns and a residence for the family—all built of logs. The station was the stopping point for stages running from Sauk Center to Fort Wadsworth, now Fort Sisseton. Four horse stages covered the trail which was also used by oxcarts three times a week. All supplies were brought from Sauk Center. The first saloon was established at Gager's Station, with a barrel of whiskey and a tin cup as its equipment.

The first settlements of which there is authentic record were made in the township of Framnas in 1866. Among the first settlers were a number of men from the East and South who had money they wished to invest in this new country. Most of them bought tracts of several thousand acres of land and started "bonanza wheat farms." Dr. Heenan of Pennsylvania and Dr. Sutherland of New York were among these investors. When the wheat ventures failed to make expected returns these men turned to their professions or to other businesses or left the county. Their farms were broken up into small tracts.

Data for this history were collected from the files of Stevens County newspapers: *Frontier Business*, J. C. Chandler and J. P. Cooper, editors and publishers, which became the *Stevens County Reporter* in November, 1876, W. H. Graves, Editor and Publisher; which was succeeded by the *Stevens County Tribune*, April 8, 1880, W. J. Munroe, Editor and Publisher. Other information was obtained from the Illustrated Album, Biography of Pope and Stevens Counties, published in 1880; Historical Contributions by Calvin L. Brown, Chief Justice of the Minnesota Supreme Court; National Archives and Records Service, Washington, D. C.; drug store files; office of the Minnesota State Medical Association, county office records, and from some of the oldest settlers of whom very few are left.

The first post office in the county was Scandia in the township of Framnas; later, mail was distributed at Gager's Station. In 1871, with the coming of the St. Paul and Pacific Railroad, the post office was transferred to Morris. From 1876-1887 a government stage was run between Morris and Alexandria with Nash in Framnas Township as a post office.

The first general election was held at Gager's Station in 1868; about twenty-five legal votes were cast and returns made to Pope County, and in that same year the present boundaries of Stevens County were set, although a permanent organization was not made until 1871.

The early settlers were exposed to all the trials and hardships incident to life and home-making in a new county. Those who came to Stevens County prior to 1873 were exposed to one of the worst storms experienced in this section. It is referred to as "the great blizzard of January, 1873" which continued with tremendous force and violence for three days and nights. The storm came from the northwest and extended over the entire prairie from the northern boundary of the state to Rock County. It left in its wake many who were caught in its fury and were frozen to death, and many others, who, though their lives were spared, lost both hands and feet, frozen to an extent that made amputation necessary to save their lives.

Grasshoppers were a serious plague from 1875 to 1877, and proved a severe set-back to the new country. Many settlers left and others took up trapping. Early settlers say that eagles, pelicans, elk, deer and buffalo were plentiful.

Morris was named after the chief engineer of the first railroad to come through the town. Chokio is an Indian name meaning halfway. This was the halfway point on the stage route between Gager's station and Lake Toqua, now Graceville. Hancock was named in honor of Rev. Joseph Woods Hancock, an early missionary among the Indians and settlers of Goodhue County, from where many of the early families of the Hancock community came. The town of Donnelly was first named Douglas. The change to Donnelly in 1877 was in honor of Hon. Ignatius Donnelly who owned a large farm near the village, who was elected lieutenant governor and served in Congress from 1863 to 1869.

Between 1871 and 1875, the village of Morris had a fairly rapid growth for a new frontier community. The census of 1875 gave the town 480 people. The Federal census of 1880, five years later, gave the village, exclusive of the people of the township, a population of 780. Morris was incorporated in 1878. There were no street lights except three dingy kerosene affairs supported by individuals. Streets were in bad condition. In early spring Atlantic Avenue was practically impassable for a time because of muddy conditions. The present pavement is quite in contrast with the streets as they existed in former days.

Frontier Business was the first newspaper published in Stevens County. Volume I, Number One, was issued August 4, 1876. It carried in its mast head the notice of "Republican in politics, respectable in fun and remarkable in frankness. All for two dollars a year, invariable in advance, which is business." A general feature of the early papers was the advertising of patent medicines, describing in detail such illnesses as consumption, a cold or sore throat, pimples, ringworms, catarrh, a terrible cough, et cetera.

All through the years a concentrated effort was evidently made through the papers by the Board of Health to prevent unnecessary illnesses; they urged the removal of all filth, garbage, and trash to designated dumping grounds.

In the early days sulphur and molasses, the old-fashioned antidote for spring use, the pain killer, the much-advertised cure-all "wizzard-oil" and other liquids

took care of most ailments with which both old and young were then afflicted.

City Drug Store (F. M. Terle & Co.), located on the west side of the tracks, carried the first drugstore advertisement in Stevens County, appearing in *Frontier Business,* Vol. I, No. 2, issued August 11, 1876.

Dr. E. R. Wait was the first doctor in Stevens County of whom a record has been found.

In the files of the present Arneson Drug Store, Prescription No. 1 was written on February 26, 1880, for Quinine-Sulphate and signed by Dr. Thomas Heenan. The patient's name was not given. Prescription No. 2 was written by Dr. D. R. Sutherland and No. 3 by Dr. H. L. Hulburd.

Morris suffered a measles epidemic in 1888 and a "La Grippe" epidemic in February, 1890, according to the State Board of Health.

The following is taken from a report of the Secretary of the State Board of Health, dated December 31, 1898, published in the *St. Paul Medical Journal,* 1:107-108 (Jan.) 1899.

"In 1898 Morris had what is called an unnecessary epidemic. The health officer, Dr. Hulburd, diagnosticated certain sore throat cases in his practice as diphtheria. Other physicians with similar cases called the disease tonsillitis and opposed quarantine. On October 27, I received an urgent call to visit Morris and investigate. Eleven of the twelve cultures showed diphtheria. The most pronounced case was a young school teacher. She was sick one week and the doctor insisted she did not have diphtheria. On October 28 a typical membrane and culture were positive." Morris had thirty cases of diphtheria from September 1, 1898, to December 9, 1898. "There was a great deal of acrimony displayed in Morris." The schools were closed at two different times—in all, twenty days.

In September, 1899, all school children were vaccinated for smallpox. The following excerpt is from the *Morris Tribune,* September 16, 1899: "The latest method of putting up vaccine virus is in tiny tubules, instead of on celluloid points. This keeps the virus in liquid form until applied—."

In 1876, Dr. Wait came to Stevens County as the only doctor to serve approximately 300 widely scattered people. From then until 1900 a record has been found of twenty-six physicians having practiced in the county, some staying only a short time. In the December 30, 1899, issue of the *Morris Tribune,* the professional cards of Drs. Hulburd, Spurr, Young and Caine were listed. They, with Dr. Cuff of Hancock, served the 18,721 people then in Stevens County.

"Mrs. Dr. C. A. Bennett, M.D.," is mentioned in a local newspaper, dated November 20, 1879, which states that "she will be at the Evans House and asks a share of patronage." An ad which appeared on the same date states that she is from Minneapolis and Detroit, Michigan, that she had twenty years' experience in many diseases, that she is one of the most successful lady physicians in practice, and that she also is the owner of a business manufacturing cough-drops and lozenges. Her ad continued until the end of March, 1880. Nothing more is known of her. No doubt she was an itinerant physician or a quack.

Dr. Charles Edward Caine was born on a farm at Spring Brook, near Princeton, Minnesota, on May 25, 1868. His father, Thomas Caine, and his mother, Anna Tuttle (who lived past the age of ninety-seven) were born in New York. During his boyhood years he knew the hardships of pioneer life. As a young man he taught school for several years to prepare himself financially for medical school, as he had already decided to devote his life to the service of his fellowmen through the science of medicine. He worked his way through the University of Minnesota

and was graduated in 1896. In that same year he began his practice in Elbow Lake, Minnesota. Also, that same year he was united in marriage to May Martin, the wedding taking place at Sauk Rapids on December 31. In December, 1898, he came to Morris and opened an office over Krueger's Drug Store and continued the practice of medicine in the community until his death.

During his forty-five years as a physician in Stevens County, he won to an unusually high degree the trust and confidence of the families he served. He gave readily and unselfishly of his skill and knowledge, of his patience and understanding. He showed the same consideration to all of his patients no matter what their station in life. Through the years of his practice, Dr. Caine placed his own life in jeopardy on many occasions in answering the call of his patients, especially in the winter months when blocked roads, blizzards and subzero temperatures were grave threats to travelers.

In 1925 he established the Morris Hospital in Morris, and owned and operated it successfully to the great benefit of the community. In 1951, it was merged with the Stevens County Memorial Hospital.

Dr. Caine was always interested in public affairs, local as well as state and national. His prime interest, however, was Morris and its surrounding territory, and he gave generously of his time, effort and money to its progress. He was definite and outspoken in his beliefs, but even those who did not share his viewpoints heard him with respect and regard.

Dr. Caine held many positions of trust and responsibility in Stevens County. In 1936, he was elected to the City Commission and re-elected in 1940. Two years later (1942) he resigned from the commission and was elected mayor, a position he held at the time of his death. Both posts were filled capably and efficiently. He served as county physician, as county coroner for sixteen years, as city health officer and county health officer for many years. He was a member of the Board of Education and served as president of the board. He had been physician in Morris for both the Great Northern and Northern Pacific railways.

Dr. Caine served for a number of years on the State Board of Medical Examiners and was president of the body for a time. During World War I he was Stevens County examining physician under the Selective Service Program.

Dr. Caine was a charter member of the West Central Medical Society and was a member of the Minnesota State Medical Association and the American Medical Association. He was a member of the Golden Sheaf Lodge No. 133 A.F. & A.M., of Mt. Lebanon Chapter No. 47, Royal Arch Masons, and of Bethel Commandery No. 19, Knights Templar. He was a member of Morris Aerie No. 620, Fraternal Order of Eagles, and was a charter member of the Morris Civic and Commerce Association.

Dr. Chas. E. Caine passed away at the Morris hospital on Saturday morning, April 15, 1944, from coronary thrombosis. He had been in failing health during the previous winter, but there were comparatively few days he was not at his office, attending to hospital duties or making calls throughout the countryside. The same dogged determination that often, during half a century of medical practice, had stood him in good stead as he battled illness and the threat of death among his patients, kept him at his work during the last months despite his poor health. Those last days were as he would have wished them—busy at his chosen work until only a day or two before death came.

Few persons have been so generally mourned in the community as Dr. Caine. The news of his passing spread quickly over a wide territory, and the grief which it occasioned is that which comes only with the loss of a very close, esteemed and

helpful friend, one who has earned a place of honor through a lifetime of service to his fellowmen. Impressive tribute was paid to Dr. Caine at the funeral services held in the Morris Armory. Every available seat in the large auditorium was filled by those from every part of the county and greater distances. It was the largest crowd ever to attend a funeral in Morris. The funeral services were conducted by Rev. E. S. Ede, pastor of the First Lutheran Church. He struck a responsive chord in the hearts of his listeners with his eulogy of Dr. Caine's life of service. He was buried in Summit Cemetery, and Masonic services were conducted at his grave.

Dr. Caine was preceded in death by his wife, who passed away on March 15, 1930, and by a son, John A. F. Caine. Left were a daughter, Mrs. Lois Caine McElligott of Morris; a sister, Mrs. Herbert Howard of Sebeka; a brother, Fred W. Caine of Ritchie, Saskatchewan, Canada; a niece, Mrs. Fred Orth of Grand Forks, N. D., who was reared by Dr. and Mrs. Caine; and a granddaughter, Sheila McElligott. Mrs. McElligott and daughter later moved to Minneapolis.

Dr. William S. Cuff came to Hancock in 1897 shortly after his graduation from the University of Minnesota in the same year. In 1898 he planned to move to Morris, but nothing came of it. Close to the turn of the century, he located in Benson, Swift County, and stayed for almost a year. He returned to Hancock in the summer of 1900. A local newspaper in February mentioned the need for a physician in Hancock and an item of April 28 announced that "Dr. Cuff decided to return to Hancock. . . . Dr. Daignault will take up Dr. Cuff's practice in Benson."

Dr. Cuff was a busy practitioner in Stevens County; many incidents of injuries and illness attended by him are mentioned in the newspapers. When he left, the *Morris Tribune* of May 2, 1903, gave him a fine send-off: "Dr. and Mrs. Cuff left for St. Paul, their future home. . . . Hancock cannot afford to lose such of her citizens neither in a social nor in a business way, and many friends will regret their departure. . . "

In St. Paul he formed a partnership with Dr. B. J. Hawkins, and practiced for many years with an office on Wabasha street. He joined the Ramsey County Medical Society not very long after his arrival in St. Paul (on October 26, 1903), but apparently did not remain a member for very long nor take an active part in it. He retired in 1943 and is still (1957) living in St. Paul.

Dr. Cuff was born in Nobles County, Minnesota, in 1875, but left that county at the age of about ten. He graduated from University of Minnesota Medical School in 1897.

Dr. Stephen H. Duley was born in Russia, Herkimer County, New York, June 8, 1828,* the son of Benjamin and Amy A. (Harmon) Duley. At the age of fifteen, he started in the world by himself, leaving home in the most destitute condition. He had no resources but in himself, and acquired his education by studying at night. He attended an academy for a few months but was unable to continue on account of lack of means.

For the next four years after leaving home, he was engaged at whatever he could find to do, and only by hard work and economy was he able to succeed. At the age of nineteen, he commenced the study of medicine at Plessis, Jefferson County, New York, with Drs. Hutchins and Hosford. After being with them one year, he was married to Miss Phoebe Fox of the same county. They moved to

*His obituary in the *Morris Tribune* gave June 9 as the date of birth.

Gravesville, Wisconsin, where Dr. Duley entered upon clinical work with Dr. Alden and studied and practiced at the same time with Dr. Alden. Five or six years later he moved to Westfield, Marquette County, Wisconsin, and shortly thereafter went to Chicago and attended Bennett Medical College. He was graduated from this college in 1878, and returned to Westfield and again opened an office. He remained there until 1882 when he came to Minnesota and opened an office at Benson, Swift County, where he practiced until November 28, 1883, when he came to Morris, Stevens County. His professional card in the *Morris Tribune* read as follows: "Dr. S. H. Duley, Physician and Surgeon. Office over Larson and Nelson's Store. A graduate of Bennett Medical College, Chicago, Illinois. Twenty-five years' experience in constant practice. Female diseases a specialty."

Dr. Duley's living quarters were in the rear of his office. His practice gradually increased and he was considered to be one of the successful practitioners of the county.

Dr. Duley was rather eccentric. His hair was very white and wavy and he wore it in long ringlets hanging on to his shoulders. Around town he wore a long frock coat, a tall silk hat and gloves, and carried a cane. He told Dr. Caine of a severe case of postpartum hemorrhage, several years before in some back woods in Wisconsin. It was in the winter time, so he and the woman's husband carried pails of water from a near-by spring and poured it over the poor woman all night long and finally stopped the hemorrhage.

In his politics, Dr. Duley was a Democrat. He was elected delegate to the Democratic State Convention in June, 1898. He served as health officer for several years and received recognition many times for the manner in which he kept the city clean and free from weeds, for inducing the Great Northern Railway to drain their right of way between the depot and Atlantic Avenue, and having the place filled and leveled. Later, he was removed from the position of health officer by the village council for refusing to co-operate with the mayor and council on quarantine. He was appointed examining physician for Stevens County by the Commissioner of Pensions and was county coroner for some time.

In 1889, Dr. Duley filed a homestead entry on the lake, two and one half miles from town on the Graceville road, and he was given credit for good business sense. In August, 1900, his office was destroyed by fire (he had had the same misfortune once before, losing his library, instruments, et cetera). This time, too, he lost his library and his whole equipment. He was overcome by smoke trying to save some of his belongings. The loss hit him hard, as he carried no insurance.

In 1891, he moved back to Benson, but this was not a lucky move. In July, he spent almost a month ill in a St. Paul hospital and in August of the same year he returned to Morris where he rented an office over J. J. Carney's meat market. In 1892 he built an office on Fifth street, opposite Cline and McDonald's meat market.

Dr. and Mrs. Duley were the parents of five children, only one of whom lived; she was Ala M. who married Levi A. Smith of Westfield, Wisconsin.

Around 1896 Dr. Duley's health began to fail to the extent that he had to employ an assistant. Finally, in the early part of 1903, he had to give up his practice and go to Spencer, Iowa, where his daughter lived. In November, 1903, Dr. Duley was brought back to Morris as his relatives in Iowa refused to take care of him. He was very low physically and had to be cared for by the county.

He died a short time later of cirrhosis of the liver, and was buried from the Assumption Church. His obituary appeared in the *Morris Tribune* of December

26, 1903, which stated at the end "Though never prominent in the profession here in Morris, his condition excited the sympathy of many friends, so that in his sickness he was cared for and given a Christian burial."

Dr. John O. Dyrnes practiced in Morris only a short time—from December, 1898, to February, 1899. His career as a missionary physician in Madagascar, however, is sufficiently interesting, to permit a somewhat extended biographical sketch. After his graduation in 1898 he located for a short time in Hanley Falls, Yellow Medicine County, for which reason his biography is included in the medical history of Yellow Medicine County and most of the following sketch is taken from this history.*

Dr. Dyrnes was born May 5, 1867, on the island of Smolen in Norway. In spite of being a weakling in infancy, he developed normally except for marked nearsightedness. Although he had an intense interest in education, the circumstances at home would not allow any schooling. He lost his father when he was only six years old. His older brother Anton emigrated to America, and, at the age of sixteen, John followed him. He tried his hand at anything to earn enough to allow him to go to school. Not until he had reached young manhood was he able to attend Baldwin Seminary of St. Paul (later Macalester College), and even then only by working as janitor. Later he went to Augsburg Seminary, from which he graduated in 1892. It seems that it was during this period that the thought of becoming a missionary reopened, because, soon after his graduation from Augsburg Seminary, he entered the Theological Department of Augsburg, graduating in 1895. It is said that he commenced his medical studies while going to the School of Theology, but he did not receive his M.D. degree until three years later (in 1898) from the Minneapolis College of Physicians and Surgeons.

Although he had made the decision to become a missionary physician, he practiced in Minnesota waiting for an opening in the mission field. A friend in the Lutheran church was no doubt responsible for his going to Hanley Falls. His stay there was short, as we find him in Morris in December 4, 1898. He remained there until late in 1899, when he received his call for mission service.

His studies in Paris for the necessary degree from the University of Paris, his ordination to the Christian ministry, his arrival at Manasoa, Madagascar, in 1900 are well described in the biographical sketch for Yellow Medicine County. We learn there of his devotion to his chosen field, his illness, the loss of all of his possessions in a fire. In Madagascar, he married Miss Sarah Johnson of Lowry, Minnesota, also a missionary, who ably helped him in his work.

He has been described as a true Nordic type, with light curly hair and blue eyes, and of tall stature. An outstanding feature was his cheerfulness and his contagious humor; it seems he was a true optimist.

He came back to the United States only once for a visit—in 1919 when he came to Minneapolis. Another visit was planned in 1937, but his wife became ill and died. When he had reached retirement age, the mission board did not recall him, seeing that Madagascar had become his real home. Although his health began to fail, he continued with his work until diabetic cataract put an end to his labors in 1943; diabetic gangrene made his last few months very painful, and he died on December 7, 1943. He was buried in Madagascar.

Dr. E. M. Elisey was in Chokio around the turn of the century, coming there as a young man with his wife. They had their first child in Chokio which, however, did not live long. His stay there was of short duration. Nothing more is known about him.** According to unpublished notes on the medical history of

*"Medical History of the County of Yellow Medicine" by Mildred E. Lee, MINNESOTA MEDICINE, 36:1270-1272, 1953.

**Communication from Mrs. Oden L. Henry, March 6, 1956.

Stevens County by Drs. C. E. Caine and F. W. Behuler, he was the fifth physician to locate in Chokio. A *Dr. James R. Elsey* is said to have come to Chokio in 1901 after having practiced for a while in Illinois following his graduation. It seems very likely that these two refer to the same physician.

Dr. James R. Freeman of Washington, D. C., came to Morris in April, 1881, and purchased the M. M. Moan Drug Store, renaming it J. R. Freeman and Co. He practiced in Morris a little over a year, then sold the drugstore and moved to Minneapolis late in August, 1882, where he is listed through 1893 but not after 1896.

Dr. Freeman seemed to have gained a good reputation in Morris in this short time and apparently made many friends. According to an item in the local newspaper of August 31, 1882: "Dr. J. R. Freeman left Tuesday night for Minneapolis where he has permanently located. During the time Dr. Freeman has been in Morris he has gained an enviable reputation as a skillful physician, has made a lot of friends and all regret his departure. While we regret his departure, we wish him success in his new field of labor."

He was a graduate of the National Medical College, Columbian University, Washington, D. C., in 1879. Nothing is known of his background or when and where he died.

Dr. Edward Spurr Frost was frequently called to Stevens County in the 1870's, although he was located in Willmar, Kandiyohi County. His influence was sufficiently felt at all points along the railroad between Willmar and Morris to include him in this history.

Dr. Frost was born in St. John, New Brunswick, in 1843, and was graduated from the University of Pennsylvania in 1866. Then he took postgraduate work in London, Heidelberg and Paris. When the Franco-Prussian war broke out, he joined the Red Cross, but resigned after the battles of Gravelotte and and Mars la Tour. After receiving a postgradute degree in France, he came to the United States. After a short stay in New York he came to Minnesota, settling in Willmar in 1871, as the first physician to locate permanently in Kandiyohi County. He became its outstanding pioneer physician. Dr. Frost died in 1916.

(To be continued in January issue)

Minnesota Blue Shield-Blue Cross

Minnesota Blue Shield recently announced an extension of coverage to include benefits for diagnostic x-rays and diagnostic laboratory services, to become effective on a staggered basis, starting August 1, 1959 and thereafter depending upon the non-group billing date, or, in the case of group subscribers, the next annual renewal date of the group.

To clarify this extension of Blue Shield coverage it should be stated that benefits for such diagnostic services by doctors of medicine will be available when necessary to the diagnosis of or treatment of a sickness or injury. These diagnostic procedures may be carried out in the doctor's office, the patient's home or the out-patient department of a hospital as long as rendered, supervised or directed by a doctor of medicine who customarily bills for his services.

The diagnostic program will not include benefits for x-ray and laboratory services when done in connection with routine physical exams, check-ups, pre-employment or pre-marital exams, etc., but only in those instances where necessary to the diagnosis of or treatment of an illness or injury.

While a Schedule of Payments for the diagnostic services has been forwarded to all participating physicians payment will be provided on the basis of the doctor's customary fee but not in excess of the Schedule.

A maximum of $50 for diagnostic laboratory services and $50 for diagnostic x-ray services under Plan A and $75 for laboratory and $75 for x-rays under Plan B will be available to each participant subscriber for any period of twelve consecutive months.

The extension of the Blue Shield contract to include such benefits has come at the request of many Blue Shield group and non-group subscribers as well as physicians throughout the state. It is the result of the efforts of Minnesota Blue Shield and Minnesota physicians who have developed the program to provide a valuable tool for the prepayment of out-patient diagnostic services.

At the end of 1958 there were 123,038,000 persons nationally participating in voluntary prepayment hospitalization plans reported the Health Insurance Council in its 13th Annual Survey. This represented a gain of more than 1½ million persons over 1957. Over 55,200,000 persons were enrolled in Blue Cross compared to 78,900,000 enrolled through various insurance companies and 4,800,000 through independent plans. Approximately 15,900,000 persons have duplicate coverage.

Hospitalization benefits paid by prepayment plans totaled $2,589,000,000 during the year. Hospitalization expense incurred by Blue Cross members totaled $1,303,000,000 averaging approximately $24 per person covered per year. The $1,186,000,000 hospital expense incurred by insurance companies' subscribers represents an average annual value of approximately $15 per person covered and the $100,000,000 expense incurred by subscribers of independent plans represents an annual benefit value of approximately $20 per person covered.

In Minnesota, Blue Cross hospitalization expense incurred during the first seven months of 1959 totaled $22,369,057 representing an average annual value of Blue Cross benefits per person covered of $33.70.

Accidental injuries caused the hospitalization of 22,599 Minnesota Blue Cross members during the period; benefits incurred exceeded $1,400,000. Obstetrical care was the second leading reason for Blue Cross hospitalization with 19,685 subscribers hospitalized incurring benefits approximating $3,100,000. Respiratory diseases ranked third in causes of Blue Cross hospitalization expense incurred, 18,802 subscribers hospitalized . . . benefits exceeding $2,200,000. Digestive diseases ranked fourth in leading reasons for hospitalization, 16,975 hospitalized subscribers and benefits exceeding $3,700,000.

THE MACABRE DEATH DANCE AND THE LONG, LONG SLEEP

The lightning-like speed and the world wide race in harnessing the Herculean power of the atom, awes the imagination and sobers one's thinking concerning what the new Atomic Era has created and to where it will lead us. No sooner had this power been introduced to the world when a multitude of startling and perplexing problems challenged the technological, metallurgical and thermodynamic scientist, in coping with what the atom brought into the world. When Watt invented the steam-engine in 1764, there was no metal nor temperature problem to solve. The ferrous material that was used was adequate for the moderate steam pressure and temperature of that time. It was not until World War I that definite practical problems began to arise—due to inadequacy of the material used—in regard to withstanding this high temperature. The Civil War gave birth to the armored battleships. For several decades, the contest between the manufacturers of armor and of the armor piercing shells of the battleships was a challenging game on the Aberdeen proving grounds in Maryland. This could be illustrated by numberless examples, to reveal the technological and metallurgical problems that were created at the turn of the century.

The Manhattan Project, climaxing the detonation of the first atomic bomb July 16, 1945, at Los Alamos, New Mexico, ushered into the world the most startling and sobering scientific event of all time. The press, asking for a statement, got the following replete and succinct statement from the philosopher scientists, "Peace or Perish"! Daily, the admonition is revealing this statement of fact to the world.

World War II was no sooner ended, hastened by a couple of atomic bombs dropped on Japan, when a new and different "Cimarron" race was on—this time, to corral atomic power. The United States was the only nation on earth that possessed the "know how" of the atomic bomb. But, before the decade had passed, this secret became general knowledge. Immediately, the pace of the race for testing atomic war material, accelerated accordingly. But, after a decade of testing, the scientists revealed that the world racetrack was becoming so cluttered with long-lived, radioactive fallout, that the nations began to realize and to appreciate more fully, what the philosopher scientists already knew at the first detonation of the bomb in 1945. In the decade of 1945-1955, accumulating, long-lived, radioactive fallout was generated at a tremendous rate—a pace too rapid for the safety of all living matter. While scientific facts were accumulating, the radioactive fallout was blanketing the earth. Possibly, some of the world leaders saw a striking similarity in the long-range destruction of the fallout, to the mythological cloak of Nessus, the burning garment which the jealous Dejanira gave to her husband, Hercules. The burning cloak of Nessus is with us, in the form of radioactive fallout material to which all of us are, to a certain degree being exposed, over and above that with which nature bombarded us before the atomic era. About four years ago, a physicist friend, working for General Mills, told the following story concerning a box of ruined films. The film company could not explain what had happened. The physicist quickly proved that the films had been ruined by radioactive straw in which the films had been packed. The straw was traced to the Kansas wheat fields of 1946, a year after the first bomb was detonated in New Mexico.

The September report, the latest, on milk radioactivity figures, shows that milk from the St. Louis, Missouri, and Fargo, North Dakota, areas reveal more contamination than that from any other place in the country. The amount present was below the "permissible" safe limit or level set by the national committee on radiation protection. The reports on radioactive fallout are a daily story as found in our various foods. This contamination is presumed to be caused by nuclear weapon tests in the United States and abroad. Various reports like this remind us of the familiar Julia Carney verse from "Little Things." "Little drops of water, little grains of sand, make the mighty ocean, and the pleasant land." It makes us wonder what this atomic bombardment will do over a long period of time, to all living matter in the mighty ocean and the pleasant land.

Scientists are fully aware of the colossal task the atomic era has created. To neutralize the long-lived, radioactive material continues to be the supreme challenge. So far, clean atomic bombs have not been perfected. Baking radioactive waste material in montmorillonite clay is being tried, and it has been found that this impregnated baked clay will retain the radioactive material which is not liberated in turn by the acid, alkali or water of the soil in which the clay is buried. So far as we know, this method is not being used for disposing of waste material. One would suspect that the baked clay could not withstand the terrific bombardment for any length of time, and that it finally crumbles.

The steel, lead and concrete tanks are still used for burial of the highly concentrated radioactive waste material. These tanks hold 4000 or more gallons of this waste material. This solution is so highly concentrated when buried, *that a single drop would require a billion gallons* of water to dilute it down to safety for animal and plant-life consumption. This solution remains radioactive for over six centuries before it becomes reasonably inert. The scientists also maintain that these tanks will disintegrate within a hundred years because of the severe bombardment of the radioactive solution sealed up inside. The liberated solution will then seep into the ground and water, to perform its macabre death dance, for another five hundred years plus. The scientists maintain that the oceans are not big enough to dilute this radioactive waste material to such a degree that it will not destroy ocean life. This also holds, the scientists maintain, for the good earth.

Dr. Hatch, of the Rookhaven laboratory, and Dr. Rodger, of the Argonne laboratory, estimate that by the year 2000, approximately one billion curies of waste material will have been generated in the nuclear reactor plants, this making the disposal of waste material a most serious problem for future safety of all living matter. A nuclear reactor plant for furnishing electricity for a 50,000 population city, requires an output of approximately 20 million watts. In one year it will create approximately 14 million curies of waste material, after the waste material has decayed for a hundred days. In the meantime, more nuclear plants are under construction, while nuclear tests are also being made.

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

It would seem reasonable to predict that our country is possibly contaminated with more fallout and nuclear reactor waste material than any other world nation. How near are we to the precipice? What is known is that this radiation bombardment performs in a stealthy, silent, painless, lethal manner. And this is also known—that when the sky, earth and ocean glow with radioactivity, it will be too late to turn off the symphonic music the atom plays.

If a promising drug or vaccine is discovered, the United States Public Health Department steps in to protect the public, until all tests have proven safe and satisfactory. The medical profession is then permitted to administer the medicine. The same, I believe, is axiomatic for atomic tests, because of the health hazards they create for the immediate workers and for the population at large. A worldwide problem for the scientists, health authorities, the IGY and world leader to work out!!

A dozen or more megaton or larger hydrogen bombs, striking as many heavily populated and strategic cities, of any world power within a few hours, would cause a holocaust beyond description. Should the war continue for a short time, the destruction of the country would be complete. This would be followed by such a terrific amount of radioactive fallout that no conqueror would even consider entering the country. Not even living bacteria would remain to decay the dead.

World leaders, irrespective of their government philosophies, are becoming fully aware of what the "equilibrium of horror" of atomic war material can do to the world, if unleashed! It requires no prophetic wisdom to predict that the then following war would be fought with sticks, stones and clubs.

The atomic era is here! A fitting project for the IGY organization would be the establishment of a *world holiday* for commemorating the birth of the atomic era, its beautiful potentialities, and especially for the banishment of future world wars. The succinct and replete admonition the philosopher scientists gave the world after the first atomic bomb was detonated in 1945, "Peace or Perish," should be the motto.

If all the stops were to be pulled out in an atomic world war, the world theatre would finally be emptied of listeners while the atomic symphony was performing its macabre death dance. The final strains of the symphony would be a softly played lullaby to the long, long sleep of all living things!

Let us harken to the scientists! They have spoken. "Peace or Perish!"

"Why build these cities great!
If man unbuilded goes?
In vain we build the world
Unless the builder also grows."
—*Edwin Markham*

MEDICINE IN RUSSIA

"In the USSR improvement in doctors' professional skill is a matter of national importance," said Prof. Z. I. Yanushkevichius, director of the Kaunas Medical Institute, Kaunas, Russia, in an address before the Second World Conference on Medical Education in Chicago in September. "The state budget bears the whole expense connected with the maintenance of the advanced training institutes for doctors, medical institutes and local facilities. The same goes for traveling allowances, et cetera. A doctor need not worry about who will replace him while he is absent. The state takes care of that."

Prof. Yanushkevichius was one of more than 125 speakers from fifty-one foreign countries appearing on the medical education program at the Palmer House. The conference, sponsored by the World Medical Association, is a medium for the free exchange of scientific information and experiences between countries.

The conference has brought together nearly 1,500 medical educators, representing many races, religions, languages, cultures and countries, but all dedicated to the exchange of ideas for the benefit of mankind.

Prof. Yanushkevichius was loud in his praise of the Russian system of medical care and the training of physicians.

"In the USSR," he said, "a doctor is a state employe entrusted with an honorable task of protecting public health. Therefore, the postgraduate training of doctors is organized and conducted by the government in accordance with needs of the population."

The professor claimed that "the first advanced training institute for doctors in the world was organized by E. Eichvald in Petersburg (Russia) in 1855."

"Here," he added, "the first curricula and methods for various series of lectures and courses were elaborated. Thus a new independent system of specialization and advanced training for doctors was established in Russia."

Prof. Yanushkevichius told the medical educators from all over the world that "the specialization of (Russian) doctors in the main is carried out in the united municipal, regional and republican medical institutions." He added, too, that young doctors going into specialization are taught the fundamentals of the Marxism-Leninism concepts of socialism.

"In the big amalgamation of municipal in- and outpatient clinics, in dispensaries and in various other hospitals the young doctors are going through the courses of specialization on a mass scale guided by experienced specialists. For this purpose a three-year scheme of specialization is arranged in which are included a series of special theoretical and practical disciplines as well as subjects of general education, such as foreign languages and fundamentals of Marxism and Leninism," he said.

The speaker stated that at the present time in the USSR there are eleven advanced training institutes for doctors in which 1,562 professors and teachers are employed.

"During the last forty years," he said, "390,000 doctors have gone through a course of training at these institutes. Annually, more than 27,000 doctors go through a course of postgraduate training, almost one out of ten."

AUSTRIA SAYS "THANK YOU" TO UNKNOWN AMERICAN TAXPAYERS

Most of us pay taxes but few of us get cited in a book dedication. All the more reason to appreciate this thoughtful gesture from Austria!

The Austrian Government has turned out a book entitled, "Ten Years of European Recovery Program in Austria, 1948-1958," and dedicated the 368-page volume "to the unknown American taxpayers to whose tax contributions the Austrian economy owes the millions contributed in good will toward its reconstruction."

In a foreword, Austrian Chancellor Julius Raab adds, "We should be mindful of the fact that the means for our reconstruction were contributed by the American taxpayer. . . . To him, America's man in the street, Austria owes its thanks."

AMERICAN ASSOCIATION OF MEDICAL ASSISTANTS

More and more doctors throughout the country are coming to know what the American Association of Medical Assistants is doing to assist with the education of their members, and more and more interest is being shown by the medical societies, both county and state.

A central office with an executive secretary has been opened in Chicago and members are offered a salary replacement insurance plan comparable to plans offered to the medical profession.

Plans are under way for educational courses which

will be offered to those presently working in the field and to those interested in entering the field as medical assistants. The work in the doctor's office is highly specialized and trained medical assistants are necessary to assist the doctor and to relieve him of many of the details which are a part of the office routine.

The third annual meeting of the Association will be held in Philadelphia, October 16-18 at the Benjamin Franklin Hotel. Medical assistants and physicians are invited to attend.

Here is what a representative group of doctors have to say:

Dr. John W. Rice, Jackson, Michigan: "We in the Michigan State Medical Society are justly proud of the Michigan State Medical Assistants Society. This organization has come from a start in 1949 to an enthusiastic, ambitious, hard-working group of 1000 members at the present time.

"The State Medical Society in Michigan stands squarely behind the medical assistants and we want them to produce a standard for girls working in our offices that is so high that it will become a career program for high school graduates to shoot at.

"We hear seven reports at the opening of our annual meeting of the House of Delegates. One of these is from the President of the Michigan State Medical Assistants Society, along with the President and President-Elect of the Michigan State Medical Society and the President of the State Women's Auxiliary.

"Every County Medical Society has an Advisory Committee in counties where the girls are organized. These committees back the girls and help them with their problems. This year at our annual state meeting we are having our first state-wide meeting of county advisors. This is an effort to coordinate the thinking of the many advisory committees along with the officers of the Michigan State Medical Assistants Society.

"We in Michigan have come a long way from 1949, when the medical assistants were only an idea, to the present shoulder-to-shoulder attitude in support of medical progress in Michigan."

Dr. Fred Sternagel, West Des Moines, Iowa: "I have watched with a great deal of satisfaction the founding, growth and development of the American Association of Medical Assistants. From a small beginning a few years ago, the AAMA has won recognition from the American Medical Association and the State Medical Societies of twenty-one states where they have chapters.

"I have watched carefully the progress of this Association and observed that the highest standards of ethics have governed its activities. Some few physicians who disapprove of the movement on the basis that it tends to create a union and may result in unreasonable demands by assistants upon their employers have found nothing to substantiate their fears.

"One of the principal purposes of the Association is to encourage girls engaged in this activity to become better educated, better trained, better qualified and more capable employes in their chosen vocation. The success of this program should eventually and inevitably lead to financial advancement and adequate compensation for work performed. However, it should be remembered that if members receive more benefits from their career it will not be because of any so-called union, but rather to the higher standards of performance as a result of better training and more requirements for those who seek employment in this field.

"Physicians should welcome increased standards of work requirements and give encouragement to the AAMA because better trained assistants free the physician for other and more important duties. The time lost by a physician interviewing applicants and training girls to assist him in his office is something which may eventually be eliminated entirely through the AAMA and adoption of rules and regulations governing preparation and training of girls for work. These many advantages for the physician, together with the dignity which comes to a doctor's office through the employment of a well-trained assistant who has met prescribed work requirements and who is a member of an accredited and recognized professional association should enlist the support of every physician in the work of the AAMA."

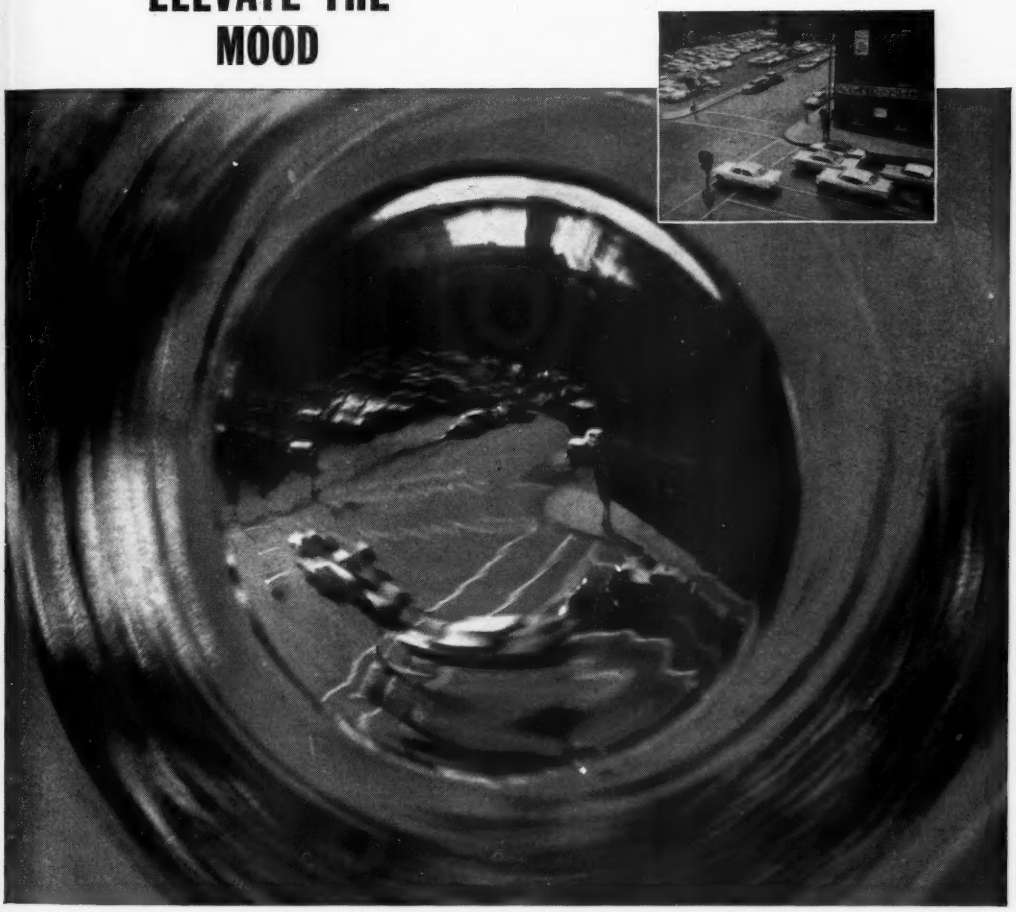
Dr. Robert L. Schaeffer, Allentown, Pennsylvania: "The practice of medicine in recent years has become very complicated, and the work of the medical assistant employed in the physician's office has consequently become complex. There are many facets in medical practice and in the work of the doctor's assistant so that an efficient girl must be trained along many channels. In addition to the particular technical knowledge her doctor requires, she must know the principles of public relations, professional relations, insurance such as Blue-Cross, Blue-Shield, and the various commercial coverages, and she should understand taxes, federal, state and local.

"The American Medical Association and some State and County Societies are aware of the need and have aided the medical assistants to form the American Association of Medical Assistants, with many component state and local groups. The Association's major aim and purpose is to offer educational programs to better equip the assistant for her work in the physician's office. Attendance at association meetings and convention seminars and sharing ideas and special skills with girls of similar interests enriches the knowledge and capabilities of the doctors' assistants so that they will render superior service to the medical profession.

"The American Association of Medical Assistants is an infant who needs the support and *'The Assistant'* of every physician in the AMA. With a strong organization, its program of education will go into high gear and ultimately it will be the doctors who will reap the greatest benefits—well-trained, efficient help for his office will be more readily available.

"DOCTOR—help the American Association of Medical Assistants—help your assistant—to better serve YOU! Urge her to become a member of this dedicated organization.'"

HALLIE CUMMINS, R.R.L.
Chairman, Public Relations Committee
American Association of Medical Assistants



Chicago, Illinois

The Venereal Disease Branch, Communicable Disease Center, 50 Seventh Street, N.E., Atlanta 23, Georgia, has established and will maintain a mailing key for the distribution of information copies of new VD educational materials as they become available.

Approximately three times a year, collections of world-wide VD literature for professional persons are abstracted and published under the title: "Abstracts of Current Literature on Venereal Disease." This is distributed by a separate mailing key.

Persons desiring to be included on either or both of these mailing keys should write to Dr. William J. Brown at the above address, requesting that they be placed on the Educational Distribution List and/or receive "Abstracts of Current Literature on Venereal Disease" routinely.

CONTROL VERTIGO, DIZZINESS... AND ELEVATE THE MOOD

with **Dramamine-*D*®**

brand of dimenhydrinate with dextro-amphetamine sulfate

"Disturbances of balance resulting from vestibular disorders have long been known to lead to severe anxiety."*

Vertigo—whether of organic or functional origin—tends to leave depression in its wake. Dramamine-*D* is a therapeutic combination designed for treatment of the entire vertigo-reaction syndrome. Each tablet contains dimenhydrinate (50 mg.) to control dizziness, and dextro-amphetamine sulfate (5 mg.) to elevate the mood.

what lurks beyond the broad spectrum?

"Broad spectrum" has evolved into an especially apt term to describe a growing number of "specialized" antibiotics. These provide the best means of destroying pathogenic bacteria which range all the way from large protozoa through gram-negative and gram-positive bacteria to certain viruses at the far end of the spectrum.

But beyond the spectrum lurk pathogenic fungi. Aggressive infections often require intensive broad spectrum antibiotic attack. It becomes more apparent every day that fungal superinfections may occur during or following a course of such therapy.[1,2] Long term debilitating disease, diabetes, pregnancy, corticosteroid therapy, and other causes may predispose to such fungal infections[1,3,4] as iatrogenic moniliasis. These facts complicate the administration of antibiotics.

Mysteclin-V controls both – infection and superinfection. Mysteclin-V makes a telling assault on bacterial infections and, in addition, prevents the potentially dangerous monilial overgrowth.[2,5-8] Mysteclin-V is a combination of the phosphate complex of tetracycline – for reliable control of most infections encountered in daily practice – and Mycostatin, the first safe antifungal antibiotic.

Case history after case history marked "recovered" provides clinical evidence of the special merit of this advance in specially designed antibiotics. When you prescribe Mysteclin-V, you provide "broad therapy" with extra protection that extends beyond the spectrum of ordinary antibiotics.

'MYSTECLIN'®, 'SUMYCIN'®, AND 'MYCOSTATIN'® ARE SQUIBB TRADEMARKS

Supplied:	Tetracycline Phosphate Complex equiv. Tetracycline HCl (mg.)	Mycostatin units
Mysteclin-V Capsules (per capsule)	250	250,000

COURSE FOR CARE OF CHRONICALLY ILL PATIENT

A one-week course for physicians, devoted to the rehabilitation care of the chronically ill patient, will be held November 16-20, 1959, under the auspices of the Department of Physical Medicine and Rehabilitation, New York Medical College—Metropolitan Hospital Center. The course will offer a review of the principles and techniques in the medical care of the chronically ill to meet the needs of the clinician, medical administrator and Public Health physician. Course content will ininclude: Physiology and Pathology of Chronic Diseases; Nutrition and Dental Care; Management of Bedridden and Incontinent Patients; Home Care Programming; Community Needs and Resources; Public Health Aspects; Self-Care Activities; Prosthetic Devices and Psychological and Social Aspects.

The tuition fee is $100.00. Traineeships for tuition, maintenance and travel are available through funds provided by the U. S. Office of Vocational Rehabilitation. Applications for the course and traineeships can be obtained directly from Doctor Jerome S. Tobis, Chairman, Department of Physical Medicine and Rehabilitation, New York Medical College, 1 East 105th Street, New York 29, New York.

REHABILITATION WORKSHOP PLANNED

The part played by the social worker in rehabilitating the crippled will be defined and strengthened in an unusual workshop to be held in Chicago in June, 1960.

The workshop will be conducted jointly by the National Society for Crippled Children and Adults and the University of Chicago, School of Social Service Administration, financed by a $13,610 grant by the Federal Office of Vocational Rehabilitation. The Grant will make possible forty all-expense traineeships for social workers presently employed in rehabilitation programs throughout the United States.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

At the annual meeting of the Northern Minnesota Medical Association held in Duluth, September 11 and 12, 1959, the following officers for 1960 were elected: President—Dr. O. K. Behr, Crookston; Vice President—Dr. L. J. Opsahl, Willmar; Secretary-Treasurer (re-elected)—Dr. C. L. Oppegaard, Crookston.

MEDICAL ALUMNI DINNER PLANNED

The University of Minnesota Medical Alumni Association will hold its Annual Dinner Meeting and Dance at the Hotel Radisson Ballroom on Friday, October 30.

A social hour starting at 6:30 p.m. will precede the dinner. Wes Barlow's orchestra has been engaged to play for the dance.

The meeting highlights the reunion of the Silver Anniversary Class annually. Dr. Wayne H. Hagen and Dr. James A. Blake, co-chairmen on arrangements for the Class of 1934, report that approximately 75 per cent of the class members plan to attend.

Dinner tickets including the social hour and dance at

NEW YORK UNIVERSITY-BELLEVUE MEDICAL CENTER POSTGRADUATE COURSES

The following courses have been announced by the New York University Bellevue Medical Center Postgraduate Medical School:

Review of Surgery of the Stomach, Duodenum and Small Intestine—October 26 through 30, 1959.

Review of Surgery of the Biliary Tract and Pancreas.—November 2 through 6, 1959.

Arthritis and Related Disorders—November 9 through 13, 1959, and May 16 through 20, 1960.

Review of Surgery of the Colon and Rectum—November 9 through 13, 1959.

Review of Surgery of the Head and Neck, Including the Thyroid—November 16 through 20, 1959.

Ophthalmic Plastic Surgery—For Specialists—November 16 through 20, 1959.

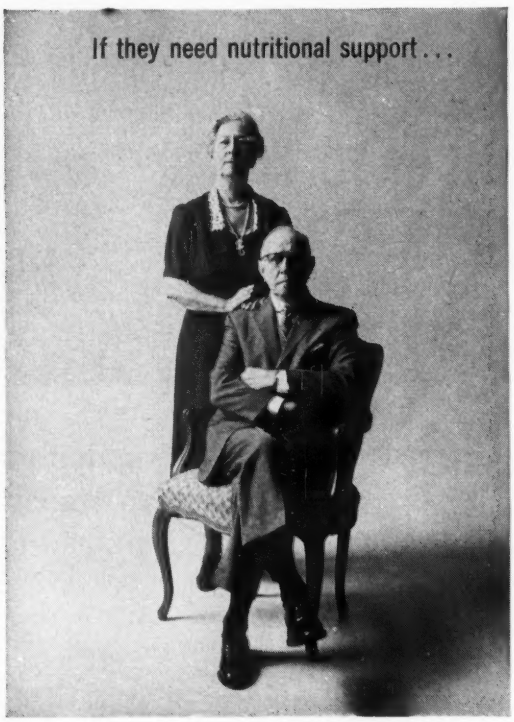
Review of Abdominal Surgical Diseases in Children—November 23 through 25, 1959.

Allergy—November 30 through December 18, 1959.

Surgery of the Cornea—November 30 through December 4, 1959.

For additional information write: Office of the Associate Dean, New York University Postgraduate Medical School, 550 First Avenue, New York 16, New York.

AUTOMOBILE TRAUMA SYMPOSIUM PLANNED



All physicians are invited by the new Methodist Hospital of St. Louis Park (Minneapolis), Minnesota, to attend an all day Symposium at the hospital, Saturday, November 14, 1959, on the subject "Automobile Trauma."

Guest speakers for this symposium include Fiorindo Simeone, Professor of Surgery, Western Reserve University, Cleveland, Ohio; and Dana M. Street, M.D., Chairman of the Department of Orthopedics, University of Arkansas.

Physicians and their wives are invited to attend the dinner at the Radisson Hotel at Minneapolis following this symposium. In the evening the subject "Safety on the Highway" will be discussed. The Hon. Kenneth A. Roberts, of the House of Representatives, will speak on "Safety Legislation."

Seven hours of Category I credit will be given by the Academy of General Practice for attendance at this symposium.

Further information concerning this program may be obtained by writing to Reuben Berman, M.D., Program Chairman, Methodist Hospital, St. Louis Park 26, Minnesota.

Woman's Auxiliary

AUXILIARY MEMBERS WARNED AGAINST NEW MAGAZINE

The following bulletin was recently received from American Medical Association headquarters:

On advice of the Advisory Committee, the Woman's Auxiliary to the American Medical Association declined to either support or make the membership list available to a new magazine, *The Doctor's Wife*. This is a new popular reading type magazine being published by a group in the East. The first issue was scheduled for September, 1959.

The County auxiliaries are asked to adhere to this policy also if they are approached for endorsement or support or for a list of members.

CORRECT ADDRESSES ARE IMPORTANT

All members are requested to note that it is very important that your county treasurer have your correct address. Please notify your county treasurer when you move.

Proper forms are provided by the Post Office to make this a simple task. It is costly for your State Office to pay both the original postage and the return and handling charges on *Gopher Doctor's Wife* and other Auxiliary correspondence.

County Treasurers please send notifications of changes of address, death and resignation to Miss Ruth Nelson, Minnesota State Medical Association, 496 Lowry Medical Arts Building, St. Paul 2, Minnesota.

Please co-operate in this project in order that files may be kept as up to date and accurate as possible, urges Mrs. Elmer M. Hill, State Treasurer.

RAMSEY COUNTY AAPS CONTEST CHAIRMAN NAMED

Members of the committee in charge of the American Association of Physicians and Surgeons Essay Contest for the coming year include:

Mrs. Wallace Gleason; Mrs. Harold Peterson and Mrs. Earl Wetzel (Parochial).

RAMSEY COUNTY NEWS

Mrs. Hans Schwyzer, President, has met several times with her newly appointed board to outline plans for the coming year.

Committees under Mrs. Phil Roy, Chairman of Ways and Means, were in charge of arrangements for the Ramsey County Auxiliary Style Show and Luncheon given at the St. Paul Hotel on September 14. The proceeds of this activity will be used in the organization's philanthropic work.

Nine members have attended an indoctrination course which has prepared them for work at the Blood Bank. Mrs. Charles Froats and Mrs. E. Russell Sterner are co-chairmen for this project of the Auxiliary for the coming year.

In Memoriam

ELMER W. ARNOLD

Dr. Elmer W. Arnold, a physician in the Adrian community for the past forty-two years, died September 2, 1959. He was seventy-six years old at the time of his death.

In 1958, the city of Adrian announced plans to name the new community hospital in honor of Doctor Arnold. The Doctor Arnold Memorial Hospital was nearing completion at the time of the physician's death.

The deceased was born in Marcus, Iowa, and received his preliminary education at Redfield College Academy, Redfield, South Dakota. His medical education was obtained at the College of Medicine, University of Nebraska.

Doctor Arnold was a member of the Southwestern Minnesota Medical Society, the Minnesota State Medical Association and the American Medical Association.

He is survived by his wife, one son, Rodney, Adrian, and five grandchildren.

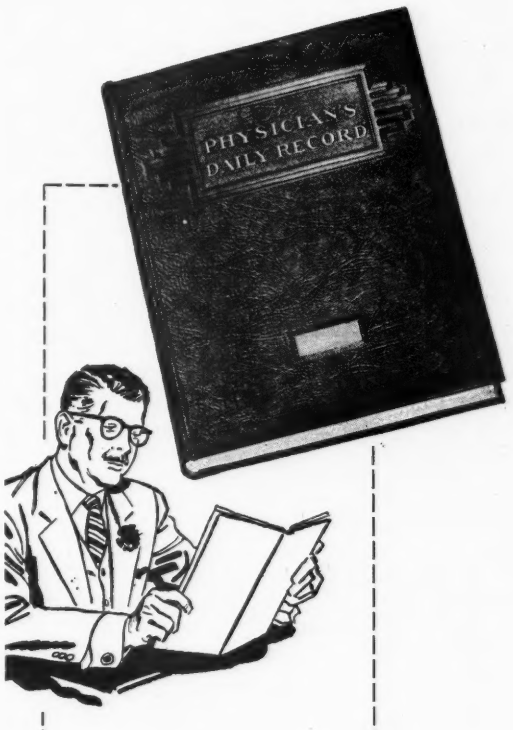
T. N. FLEMING

Dr. T. N. Fleming, St. Cloud physician, died August 24, 1959. He was a specialist in Eye-Ear-Nose-Throat He was seventy-nine years old at the time of his death.

Doctor Fleming was born in Sutton, Nebraska, where he obtained his preliminary education. His medical education was received at the University of Nebraska at Lincoln and Creighton Medical School located in Omaha, Nebraska.

He served as superintendent of schools in Lyon, Nebraska and principal of Omaha High School. Following graduation from Creighton Medical School, he practiced medicine at Cold Spring, Minnesota, and Creighton, Nebraska. After completing specializing training in Eye, Ear, Nose and Throat, he moved from Cold Spring to St. Cloud. Doctor Fleming retired from practice in St. Cloud on November 7, 1958.

Doctor Fleming was a member of the Stearns-Benton County Medical Society, the Minnesota State Medical Association and the American Medical Association.



Surviving him are his wife, Rose Mary; seven children, Mrs. Clarence King (Donata), Lansing, Michigan, Thomas, Chicago, Illinois, Doctor Paul, Casper, Wyoming, Doctor Robert, St. Charles, Missouri, Doctor Richard, San Luis Obispo, California, Mrs. George Clark (Rosemary), Kansas City, Missouri, and Joseph, Virginia; and four brothers, Edward, Omaha, Nebraska, John, Sutton, Nebraska, William, Lincoln, Nebraska, and James, Pablo, Montana.

ROBERT L. FAUCETT

Dr. Robert L. Faucett, a member of the staff of the Mayo Clinic since 1953, died August 5, 1959. Death was caused by an accidental electric shock. He was forty-three years old at the time of his death.

Doctor Faucett was born in Independence, Missouri. He attended the University of Kansas Medical School, from which he received the degree of Bachelor of Arts

1400 Harmon Place, Minneapolis 3, Minnesota

in 1938, that of Master of Arts in Bacteriology in 1940 and that of Doctor of Medicine in 1944. In 1944 and 1945 he was an intern, and in 1945 and 1946 he was a resident in pediatrics, in the University of Kansas Hospitals. He entered the Medical Corps of the Army of the United States and then, on December 9, 1946, he was commissioned a senior assistant surgeon in the U. S. Public Health Service and was assigned to the U. S. Public Health Service Hospital at Lexington, Kentucky. On July 1, 1948, he was assigned by the Public Health Service to the Department of Psychiatry in the University of Minnesota for graduate studies in pediatric psychiatry.

Doctor Faucett went to Rochester in July, 1949, as a special worker assigned to the former Rochester Child Health Institute.

Doctor Faucett left Rochester in January, 1951, to become Director of the Prince Georges County Mental Health Clinic at the University of Maryland in College Park, Maryland.

He returned to Rochester on July 1, 1953, as a Consultant in Psychiatry in the Mayo Clinic and was appointed Instructor in Psychiatry in the Mayo Foundation, Graduate School, University of Minnesota, in 1955, and advanced to the grade of Assistant Professor in 1959.

Doctor Faucett was a member of the Zumbro Valley Medical Society, the Minnesota State Medical Association, the American Medical Association, the Minnesota Psychiatric Society, the American Psychosomatic Society, the Society of the Sigma Xi and the Alumni Association of the Mayo Foundation. He was a Fellow of the American Psychiatric Association.

Survivors include his wife and two children, Russell and Julia Ann.

EDGAR T. HERRMANN

Dr. Edgar T. Herrmann, 780 Blue Gentian Road, Egan Township, St. Paul, died August 26, 1959, at Miller Hospital after an illness of four years. He was sixty-six years old at the time of his death.

A native of St. Paul, Doctor Herrmann was a specialist in Internal Medicine. He had practiced in St. Paul for more than thirty-five years.

Doctor Herrmann was a member of the Minnesota Club, American College of Physicians, Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association.

He graduated from the University of Minnesota Medical School in 1919. He later became an Assistant Professor of Medicine at the University of Minnesota Medical School.

Doctor Herrmann is survived by his wife, Elizabeth C.; a daughter, Mrs. Elizabeth H. Cowie; a sister, Miss Eleanor Herrmann, and three grandchildren, all of St. Paul.

MATTHIAS LENT RANSOM

Doctor Matthias Lent Ransom, physician and surgeon and a resident of Hancock, Minnesota, for fifty-six years, died August 27, 1959. He was eighty-six years old at the time of his death.

Military services were conducted for Doctor Ransom by the American Legion Post of Hancock of which he was a charter member.

LEDERLE LABORATORIES, a Division of AMERICAN CYANAMID COMPANY, Pearl River, New York

Doctor Ransom came to Hancock in 1903. Throughout his lifetime he was active in social and civic activities in the Hancock community. He served on the Council, was Health Officer and was the first Commander of the Hancock American Legion.

The deceased was a member of Stevens County Hospital Staff, a member of West Central Medical Society and served as its president, a Life member of the Minnesota State Medical Association and the American Medical Association.

In addition, Doctor Ransom had served as surgeon for Great Northern Railroad. He was affiliated with the Democratic party and served many years on the county committee.

Doctor Ransom was born at Ulster, Pennsylvania, on October 20, 1873, the son of William and Marian Ransom. He graduated from the Spencer, New York, high school in 1896 and entered Jefferson Medical College that fall.

Upon graduation from medical school in 1902 he began his practice at Foley, Minnesota. In 1903, he opened an office in Hancock where he practiced until his retirement.

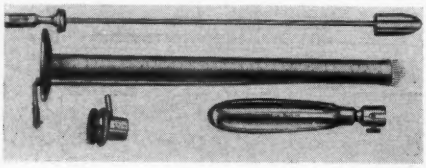
Doctor Ransom served as a First Lieutenant in the first World War enlisting on August 1, 1917. He was promoted to Captain and served overseas from August 1, 1918 to May 30, 1919. He was discharged in June of 1919 and returned to Hancock.

Survivors include his sister, Mrs. H. A. L'Amoreaux of Spencer, New York, six nieces and nephews.

GUSTAVE L. RUDELL

Dr. Gustave L. Rudell, a veteran Minneapolis physician, died August 8, 1959. He was eighty-three years old at the time of his death.

Doctor Rudell was born in Sweden. He came to the United States at the age of sixteen and later enrolled at Gustavus Adolphus College in St. Peter, Minnesota. He received his medical education from the University of Minnesota Medical School.



Following graduation, he interned at Bethesda Hospital in St. Paul and practiced medicine at the Plaza, North Dakota Indian Reservation. He did Postgraduate work in Vienna, Austria, and served as Captain in the United States Army Medical Corps in World War I.

Doctor Rudell established his practice in the Camden area of North Minneapolis in 1920. He was interested in promoting and preserving Swedish culture and was a member of the Odin Male Chorus, the Swedish-American Institute, the Swedish Pioneer Historical Society, the Swedish Cultural Society and Svenska Sallskapet.

Doctor Rudell was also a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. In 1957, he was honored by the Minnesota State Medical Association for fifty years of practice. He was a Thirty-Second Degree Mason and a member of the Zuhrah Temple of the Shrine.

Survivors include two sisters, Amanda Rudell, Lafayette, Minnesota, and Fanny Rudell, Sweden; eight nieces and two nephews.

The Physician's Diary

A number of Mayo Clinic staff members recently received promotions. They are: Medicine—**Drs. David T. Carr, C. H. Hodgson, R. M. Salassa** and **L. E. Ward** to Associate Professor; **Raymond V. Randall, R. A. Rovelstad** and **H. H. Scudamore** to Assistant Professor; Biophysics—**A. L. Orvis** to Assistant Professor; Dermatology—**Richard K. Winkelmann** to Assistant Professor; Pathology—**R. C. Bahn** and **E. H. Soule** to Assistant Professor; Surgery—**William H. Bickel** to Professor, **Oliver H. Beahrs** to Associate Professor, and **W. H. ReMine, Jr.,** to Assistant Professor; Neurology—**Clark H. Milikan** to Professor, **David Daly** to Associate Professor, **Norman P. Goldstein** and **J. G. Rushton** to Assistant Professor; Ophthalmology—**Robert W. Hollenhorst** to Associate Professor, **Thomas P. Kearns** and **Theodore G. Martens** to Assistant Professor.

* * *

Glencoe physician, **Dr. D. R. Navratil,** recently announced his decision to stay in Glencoe despite an opportunity offered him to join the surgical department of a medical group in Virginia.

* * *

Dr. Victor Johnson, Director of the Mayo Foundation, will serve as deputy president of the Second World Conference on Medical Education. Doctor Johnson also served as chairman of the Program Committee for the conference held recently in Chicago at the Palmer House.

* * *

Chaska physician, **Dr. G. T. Schimelpfenig,** recently left for Europe. While in Europe, Doctor Schimelpfenig participated in the Eleventh Annual International Meeting of the Experiment in International Living in Grenoble, France, August 29 through September 4.

* * *

Dr. John S. Lundy, recently retired from the Board of Commissioners of the Mineral Springs Sanatorium. Replacing him was another Mayo Clinic physician, **Dr. Herbert W. Schmidt.** Doctor Lundy had served on the Board since September 1952.

* * *

The new member of the research team at Mount Sinai Hospital, Minneapolis, is **Dr. Fletcher A. Miller.** He has been appointed Director of Surgical Research and Teaching at the Hospital.

* * *

Dr. Magnus C. Petersen, Rochester, announced plans to retire March 1 as Superintendent of the Rochester State Hospital. Doctor Petersen will enter the private practice of psychiatry in Rochester after seventeen and one-half years as head of the Rochester institution.

* * *

Lake Wilson physician, **Dr. T. T. Harada,** announced recently that he will be leaving Lake Wilson, after eight and one-half years of practice, for Redding, California, where he has accepted a position as a staff surgeon at Shasta County Hospital.

The East Central Medical Association held a meeting in Mora recently at which **Dr. Robert Howard,** Dean of the Minnesota Medical School, was the featured speaker.

* * *

Dr. James J. Anderson, Mankato, recently announced plans to move to Minneapolis. Doctor Anderson has practiced medicine in Mankato for nine years and his departure is not scheduled until next February.

* * *

Among guest speakers listed for the program of the Forty-first National Meeting of the American Institute of Chemical Engineers, September 27-30 is **Dr. Charles W. Mayo,** Rochester. Doctor Mayo's address is titled "Health, An Instrument for Peace."

* * *

Drs. E. E. Zemke and **Robert Schulz,** Fairmont, recently announced the addition of **Dr. Robert W. Gustafson,** Fairfax, to their staff.

* * *

The Olmsted Medical Group recently annonced the resignation of **Dr. John R. Watson.** Doctor Watson has been affiliated with the group since 1955. The resignation takes effect October 1.

* * *

Dr. Hobert J. Setzer, Jr., Minneapolis, recently joined the Internal Medicine staff at the Mankato Clinic.

* * *

A recent appointment to the Mayo Clinic staff is **Dr. Philip J. Osmundson.** Doctor Osmundson is a consultant in medicine.

* * *

Ellendale physician, **Dr. Morton Roan,** recently announced that he is unable to handle the duties of the new medical center in Ellendale because of ill health. It was later announced that Doctor and Mrs. Roan have moved to the Twin Cities.

* * *

Drs. Khalil G. Wakim and **Jesse L. Bollman,** Mayo Clinic, are co-authors of a book "Chemical Quantitation of Epinephrine and Norepinephrine in Plasma," recently published by Charles C Thomas, Springfield, Illinois. Senior author of the book is Doctor William M. Manger, a former fellow in medicine of the Mayo Foundation.

* * *

Dr. David P. Anderson and other members of the Austin Clinic staff had a University of Pennsylvania medical student working with them this summer. The student has been working for a preceptorship. Doctor Anderson has helped five students in this capacity. Doctor Anderson is a gradaute of the University of Pennsylvania.

* * *

The officers of the Forest Lake Memorial Hospital Association have signed an agreement with **Dr. G. M. Ruggles,** of that community, whereby the association will acquire the equipment of Doctor Ruggles' Forest Lake Clinic Hospital when the proposed new Memorial Hos-

■ Exhibits unusual analgesic properties, different from those of any other drug ■ Specific and superior in relief of SOMAtic pain ■ Modifies central perception of pain without abolishing natural defense reflexes ■ Relaxes abnormal tension of skeletal muscle

SOMA™

N-isopropyl-2-methyl-2-propyl-1, 3-propanediol dicarbamate

■ More specific than salicylates ■ Less drastic than steroids

■ More effective than muscle relaxants

SOMA has an unique analgesic action. It apparently modifies central pain perception without abolishing peripheral pain reflexes. SOMA is particularly effective in relieving joint pain. Patients say that they feel better and sleep better with SOMA than with previously used analgesic, sedative or relaxant drugs.
SOMA also relaxes muscle hypertonia, with its stresses on related joints, ligaments and skeletal structures.

ACTS FAST. Pain-relieving and relaxant effects start in 30 minutes and last 6 hours.

NOTABLY SAFE. Toxicity of SOMA is extremely low. No effects on liver, endocrine system, blood pressure, blood picture or urine have been reported. Some patients may become sleepy, particularly on high dosage.

EASY TO USE. Usual adult dose is one 350 mg. tablet 3 times daily and at bedtime.

SUPPLIED: Bottles of 50 white coated 350 mg. tablets.
Literature and samples on request.

pital opens for business in Forest Lake. Under the terms of the agreement, the full purchase price is $40,000 of which $15,000 is to be deducted as a gift to the new hospital by Doctor Ruggles. The balance of $25,000 will be paid on an installment plan after the new hospital is assured.

* * *

Dr. Wendell M. Swenson, St. Peter, has recently been appointed to the staff of the Mayo Clinic, as a consultant in Clinical Psychology.

* * *

The Olmsted Clinic recently announced that Dr. **John O. Flugel** has been elected a partner in that group.

* * *

The Mankato Clinic recently announced the addition of **Dr. John L. Marso** to their obstetrics and gynecology staff.

* * *

Dr. Juergen E. Thomas, Mayo Clinic, has recently been appointed to the staff of the Mayo Clinic as a consultant in Neurology. Doctor Thomas previously was assistant to the staff in Neurology.

* * *

The community of Frazee, Minnesota, recently honored its only resident physician, **Dr. Henry C. Otto,** for forty-two years of medical practice. Doctor Otto practiced medicine in Vergas before moving to Frazee. Doctor Otto has practiced medicine for over half a century in Minnesota.

* * *

Recently appointed to the Mayo Clinic staff as a consultant in Medicine is **Dr. Richard H. Ferguson.**

* * *

A former physician from St. Paul, **Dr. J. L. Purdie,** has joined **Dr. G. T. Midboe** in the practice of medicine in Forest Lake.

* * *

Dr. James G. Delano, formerly of Philadelphia, has been appointed to the staff of the Mayo Clinic as a Consultant in Psychiatry.

* * *

Recently named as members of the Medical Advisory Committee to the National Foundation in St. Cloud are **Drs. Richard Kline** (Chairman), **James Zelleny, Leo Temp,** and **Charles Donaldson.**

* * *

Dr. John W. Rosevear has recently been appointed to the staff of the Mayo Clinic, as a Consultant in the Section of Biochemistry. Previously Doctor Rosevear was an assistant to the staff in that section.

* * *

Dr. Russell M. Wilder, emeritus consultant in medicine of the Mayo Clinic, and emeritus professor of medicine in the Mayo Foundation, was named an honorary member of the American Dietetic Association at the Forty-Second Annual Meeting of that organization recently in Los Angeles. Prior to 1959, only ten other persons, distinguished in the fields related to nutrition, had been honored in this way by the association.

* * *

Ceylon physician, **Dr. Jack Gardner,** was appointed coroner of Martin County by the Martin County Board

(Continued on Page 1500)

whenever there is inflammation, swelling, pain

of Commissioners recently. Doctor Gardner will fill out the unexpired portion of **Dr. M. H. Marken,** who resigned as coroner earlier.

* * *

Recently elected chairman of the Minnesota Flying Physicians is **Dr. Roger Johnson,** Wayzata. Elected co-chairman of the group is **Dr. O. M. Wilbur,** Hibbing. The elections took place at a recent "fly-in" near Grand Rapids. Among speakers on the program was **Dr. C. Kent Olson,** Minneapolis. The group was formed in 1955 to promote a spirit of fellowship within the medical profession for those who have a pilot's interest in aviation.

* * *

Dr. Glenn W. Brown, formerly of Bottineau, North Dakota, recently joined the staff of the Morris Medical Center.

* * *

Drs. J. S. Siegel and **Wayne Johnston,** Virginia physicians, recently announced the addition of **Dr. Wendell P. Enggelstad,** to their practice of medicine.

* * *

Dr. Harry R. Baker, who has practiced medicine for over half a century in Hayfield, Minnesota, was recently honored by that community. Doctor Baker was honored by the Minnesota State Medical Association in 1957 as a member of the "Fifty Club."

* * *

The Litchfield Clinic recently announced the addition of **Dr. Paul Drexler** to its medical staff.

* * *

Dr. Wallace E. Mathews recently joined **Dr. R. B. Engstrom,** Mankato physician, in the practice of medicine in that city.

* * *

The six full-time doctors of the Oxboro Medical Clinic staff recently announced the appointment of **Dr. Henry S. Bloch** to their staff in the capacity as Doctor of Internal Medicine.

* * *

A native of Austin, **Dr. Charles A. Roach,** recently joined the medical staff of the Austin Clinic. Doctor Roach will be serving the Clinic in the capacity of a general practitioner.

Dr. Leslie Zieve and **Dr. Earl Hill** presented a paper on "Two Varieties of Hemolytic Anemia in Portal Cirrhosis" at the annual meeting of the American College of Physicians in Chicago in April. Dr. Hill was inducted as a fellow of the College at this meeting.

* * *

Dr. Robert DeWerd has recently joined the Owatonna Clinic. Doctor DeWerd will work in the field of general practice.

* * *

Recently appointed to the staff of Doctors Memorial Hospital, Minneapolis, are **Dr. Melvin G. Oppen** and **Dr. David W. Feigal,** Wayzata; **Dr. Roger S. Johnson,** Excelsior; and **Dr. E. Harvey O'Phelan,** Minneapolis. All are general practitioners except Doctor O'Phelan who is an orthopedic surgeon.

* * *

The Alexandria Clinic staff has a new member, Dr. **Richard Eddy,** who has joined the clinic in the practice of medicine. Doctor Eddy was recently released from the Army.

* * *

Dr. J. Purdon Martin, emeritus chief of staff in the National Hospital for Neurologic Diseases and Epilepsy, Queen's Square, London, England, gave a lecture on "Extrapyramidal Dyskinesias" at the Mayo Foundation, Rochester, Minnesota, on September 29, 1959.

* * *

Dr. Jack Berry, formerly of the Obstetric and Gynecology Department, Ellsworth Air Force Base, Rapid City, South Dakota, has recently joined the Surgical and Medical Clinic of Albert Lea, Minn.

THE CHICAGO MEDICAL SOCIETY ANNUAL CLINICAL CONFERENCE should be a MUST on the calendar of every physician. Plan now to attend and make your reservation at the Palmer House.

Congenital Heart Disease Involving the Aortic Valve

Four Cases Treated by Direct-vision Surgery

REUBEN BERMAN, M.D.
ANATOLIO B. CRUZ, M.D.
NATHAN K. JENSEN, M.D.
WILLIAM HEUPEL, M.D.
JAMES DAHL, M.D.
JOSEPH J. GARAMELLA, M.D.
Minneapolis, Minnesota

Presented in part, Minnesota Society of Internal Medicine, Minneapolis, Minnesota, May, 1959.

From Mount Sinai Hospital and Jay Phillips Laboratory, Minneapolis, Minnesota. Supported by John A. Hartford Foundation, Inc., U.S.P.H.S. Grant No. H-2610, the Free Bed Fund of Mount Sinai Hospital Woman's Auxiliary, and the Cardiac Research Committee of Minneapolis.

FOUR CASES of various types of congenital aortic valve defects have been encountered at Minneapolis Mount Sinai Hospital since 1957. Two had insufficiency, one with ventricular septal defect and one following subacute bacterial endocarditis on a bicuspid valve. Two had stenotic orifices, one valvular and one subvalvular. All were subjected to open heart surgery with excellent results in three, and failure in the case of insufficiency of the bicuspid valve. These cases are reported to illustrate some of the problems encountered in diagnosis, in evaluating the surgical indications, and in management.

Aortic Insufficiency Associated with Ventricular Septal Defect

The combination of ventricular septal defect with aortic insufficiency has been reviewed in several recent publications[1,2,3] reporting about fifty cases. The presenting symptoms are usually those of heart failure.[3] Physical signs include the classical findings of aortic incompetence, high pulse pressure, collapsing pulse, and diastolic murmur; associated with systolic murmur and thrill over the sternum.[4] The murmurs thus appearing throughout systole and in diastole may be confused with a continuous murmur of patent ductus arteriosus. The common features of high pulse pressure with attendant physical findings add to the difficulty in distinguishing patent ductus arteriosus from ventricular septal defect with aortic insufficiency. The pulse pressure, however, is less exaggerated in patent ductus.[5] A thorough discussion of the differential diagnosis is given by Scott *et al.*[1] Gross[5] suggested that the septal defect can contribute to aortic valve malposition by absence of supporting tissue beneath the valve. In the case reported by Nellen *et al*,[3] the ventricular septal defect was found eight years before evidence of aortic insufficiency appeared. These observations suggest that the septal defect is primary and aortic insufficiency the complication, probably post-natal. Previous attempts at surgical correction of these defects have resulted in uniformly poor results.

Case 1.—A thirteen-year-old girl was admitted October 27, 1957, to October 29, 1957. A heart murmur had been known since birth and she was brought in for cardiac evaluation. She had no symptoms except for slight shortness of breath on moderate exertion.

Blood pressure was 140-160/0-20 mm. Hg. The heart appeared slightly enlarged to the left. There was a heaving apical impulse. Grade IV systolic and diastolic murmurs were found over the base of the heart radiating down the left sternal border to the apex. A systolic thrill was apparent at the base. The systolic murmur also could be heard in the neck vessels and in the arms. A normal second sound was present at the base. The re-

mainder of the physical examination was reported as negative. The electrocardiogram showed left strain in a vertical heart. Cardiac fluoroscopy and radiography demonstrated left ventricular enlargement with tremendous pulsation of the ascending aorta. No valvular calcification was noted. There was no radiologic evidence of a left-to-right shunt. Right heart catheterization was normal as follows: Pulmonary artery pressure 20/10 mm. Hg., right ventricle 20/2, right atrium 5/1. Pulmonary artery oxygen saturation was 72 per cent, right ventricle 72 per cent to 71 per cent, right atrium 66 per cent to 68 per cent, superior vena cava 75 per cent to 68 per cent, femoral artery 100 per cent.

She was readmitted February 13, 1959 to March 14, 1959. In the interim she had rapidly deteriorated, developing extreme dyspnea and orthopnea. Arterial pulsation of the retinal arteries was a prominent finding. The neck vessels showed collapsing pulsations of a free aortic insufficiency. The physical findings of the heart were as noted previously, except that both the systolic and diastolic murmurs now were accompanied by thrills over the left second and third interspaces.

Blood pressure was 150/10-0 mm. Hg. The lungs were clear. The liver and spleen could not be felt. Duroziez murmur, Corrigan pulse, and capillary pulsations were obvious. Several blood cultures were negative. A retrograde aortogram showed reflux from the aorta into the left ventricle. There was no evidence of left to right shunt.

With a preoperative diagnosis of congenital aortic insufficiency, she was operated on February 27, 1959. The chest was opened through a median sternotomy. Exploration disclosed striking pulsations of the aorta. An intense diastolic thrill was palpable over the base. Total cardiopulmonary by-pass was performed employing a disc oxygenator. Following cross-clamping of the aorta, the coronary arteries were perfused with hypothermic blood to induce cardiac arrest. The aorta was incised vertically, opposite the non-coronary cusp, and the aortic valve brought under direct vision. The aortic cusps were asymmetrical, the left being the smallest and the right the largest. The right cusp was prolapsed into a ventricular septal defect 3.0 to 3.5 cm. in diameter. It was adherent on its under surface to the inferior rim of the defect (Fig. 1A). Adhesions of the cusp were lysed. The ventricular septal defect was closed by direct suture. The free margin of the right cusp was shortened, and the posterior commissure tightened by suture. During the period of repair the coronary arteries were twice directly cannulated and perfused with cold blood. The aortotomy was closed following a third coronary perfusion with warm blood. Following release of the aortic clamp, ventricular fibrillation occurred. It was reversed by electric shock. After restoration of sinus rhythm the chest was closed. The patient was returned to the recovery ward in good condition. Direct blood pressure in the radial artery was 130/50 mm. Hg. preoperative and 130/80 postoperative.

The patient had an uneventful recovery and left the hospital on the fifteenth postoperative day. Her blood pressure was 150/86. A Grade III systolic and Grade II diastolic murmur were heard at the base with no accompanying thrills. Peripheral findings of aortic insufficiency were not present. Within two months she was able to engage in such activity as horseback riding without symptoms. She has been followed for six months and continues to do well.

Comment.—In this case, catheterization failed to demonstrate the ventricular septal defect. The subluxated aortic cusp attached to the lower rim of the septal defect must have effectively occluded the interventricular communication. The physical findings during the second admission indicated an increase in the aortic insufficiency. The hemodynamic changes seem to be reciprocal: The interventricular defect diminished, the aortic insufficiency augmented, by the increasing herniation of the aortic valve cusp. The successful operative result is unique among the reported cases.

Bicuspid Aortic Valve

The incidence of bicuspid aortic valve as reported by Abbott[6] is 1.3% of congenital heart disease. Deformed bicuspid valves may escape detection on gross examination due to the marked deformity and sclerosis which occasionally obliterate all normal landmarks. Lewis and Grant[7] in their classic pathologic description of this anomaly showed that in spite of deformity or fusion of the commissures all normal tissue layers could be microscopically demonstrated. The deformity is due to subendothelial whorls of fibrous tissue which later may become sclerotic and calcified. This anomaly, therefore, can result in either a normal appearing and functioning bicuspid valve or one severely stenotic and deformed. Associated congenital cardiovascular lesions occur in 80 per cent of the cases and include coarctation of the aorta, patent ductus arteriosus, defects of the ventricular septum, and anomalies of the pulmonary valve.

Complications may result in dynamic aortic stenosis or insufficiency. Aortic insufficiency is often seen in those cases with associated coarctation of the aorta and resultant systemic hypertension.[6] Another complication of bicuspid aortic valve is aneurysm of the sinus of Valsalva and rupture.

The most widely recognized and the most serious complication, exemplified by our case, is subacute bacterial endocarditis. The fact that these valves are deformed, even though minimally, undoubtedly accounts for the high incidence, 26 per cent of associated subacute bacterial endocarditis.[8]

Conversely, Lewis found that 23 per cent of an unselected group of patients with subacute bacterial endocarditis had bicuspid aortic valves.[7]

Case 2. A twenty-four-year-old woman was admitted January 3, 1958 to February 22, 1958, in the eighth month of pregnancy, with a history of three weeks of chills and fever. "Black and blue" marks that she interpreted as bruises, had appeared on the hands and feet. She complained of tenderness in the fingertips. She had known of no previous murmur or heart disease. A diagnosis of idiopathic epilepsy was established at age sixteen. Dilantin reduced the frequency of her grand mal seizures. She had one uneventful pregnancy two years previously. No cardiac abnormality was noted at that time.

On admission in January 1958, numerous petechiae and ecchymoses were apparent. There were small hemorrhages in the retinae. Blood pressure was 124/40 mm. Hg. The heart was not enlarged; no thrill was noted. There was a Grade IV basal diastolic murmur, characteristic of aortic insufficiency, associated with a Grade III systolic murmur, both transmitted into the neck vessels. The lungs were clear. Tumor of pregnancy was

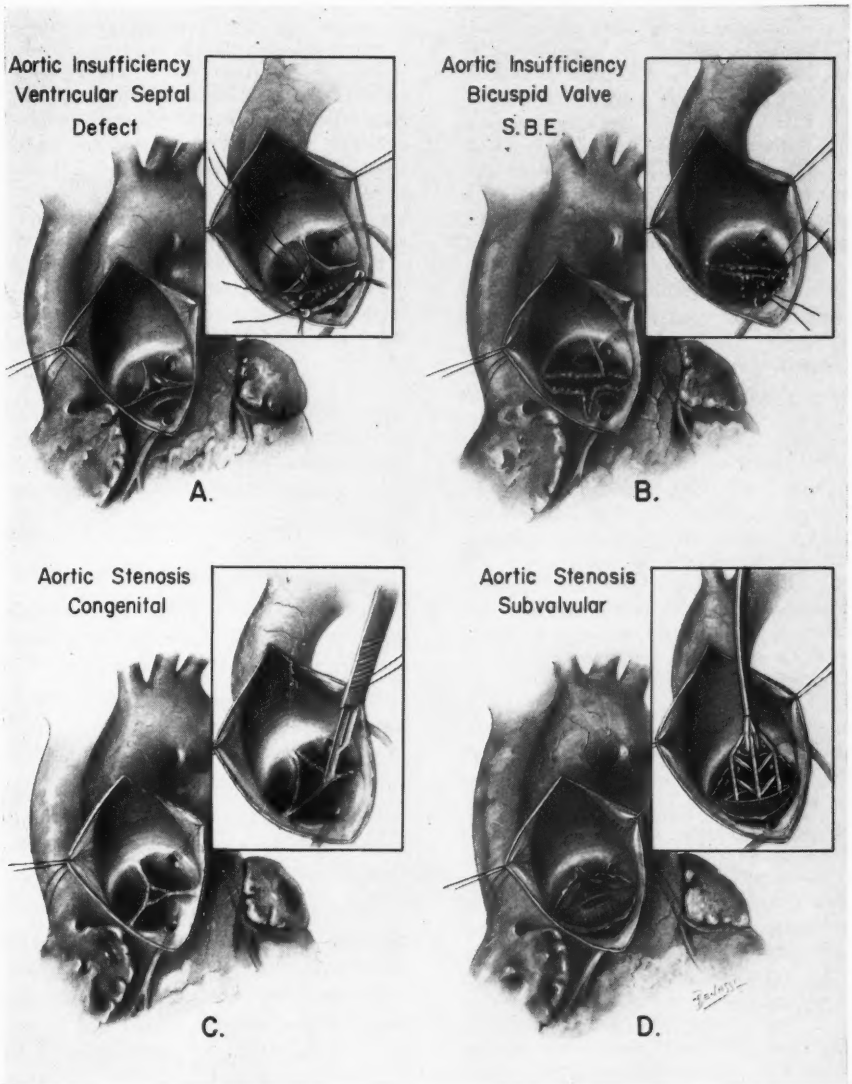

Fig. 1. Drawings showing the appearance of aortic valve area after exposure and during repair.

evident. Liver and spleen could not be felt. The hemoglobin was 11 Gm. per cent; 3,000,000 erythrocytes/mm.^{3}; and the erythrocyte sedimentation rate was 75 mm./hr. The white blood count was 11,000/mm.^{3}; 84 per cent neutrophiles, 16 per cent lymphocytes. The electrocardiogram was normal except for sinus tachycardia, 105/min. Three blood cultures revealed an alpha streptococcus sensitive to penicillin. Electroencephalogram revealed a diffuse abnormality with no focal findings. The temperature was 99.6 and she remained mildly febrile for three days. The intern's* admitting diagnoses were: (1) Pregnancy in the eighth month, (2) Epilepsy, (3) Congenital heart disease with subacute bacterial endocarditis. (In his words, "Could this be a congenital bicuspid aortic valve with SBE?") She was treated with penicillin and streptomycin for four weeks with no further fever and numerous negative blood cultures after the third day. Uneventful spontaneous delivery of a normal infant occurred on the twenty-fourth day of admission. Her diastolic blood pressure gradually dropped and at the time of discharge the readings were 120-140/16-20 mm. Hg.

She was readmitted May 9, 1958 to June 3, 1958. Dyspnea, orthopnea, cough and edema became apparent in late April, 1958. She was in obvious heart failure. Blood pressure was 130/20. The neck veins were distended and carotid pulsations were marked. Rales were heard at both lung bases. The heart was greatly enlarged. The rate was regular at 120. The murmurs had not changed. The liver and spleen were greatly enlarged. Pre-tibial edema was present. The hemoglobin was 12.3 Gm. per cent, white blood count 9,500/mm.^{3} with a normal differential; sedimentation rate 4 mm./hr. The urine was negative. Numerous blood cultures were sterile. She was afebrile. Chest x-ray showed great increase in heart size to the left, and marked pulmonary vascular engorgement. The electrocardiogram revealed a left strain pattern. The patient responded poorly to the usual management for congestive heart failure. Although the signs of pulmonary congestion diminished, she continued to show some edema and hepatomegaly.

With the diagnosis of aortic insufficiency following subacute bacterial endocarditis she was operated on June 8, 1958. The chest was entered through a bilateral thoracotomy with section of the sternum at the level of the fourth interspace. In the right hemithorax there were 100 ml. of straw-colored fluid. The heart was markedly enlarged extending to the left chest wall. A diastolic thrill was palpable over the base of the aorta. Cardiopulmonary by-pass was performed employing a disc oxygenator. The aorta was cross-clamped and the heart was arrested with potassium citrate in heparinized blood. Aortotomy revealed a bicuspid, frayed, fenestrated, and obviously extremely incompetent aortic valve (Fig. 1B).

Restoration of valve competence was attempted by suture of the fissure and cusp perforations. The commissures were reinforced by suture. Coaptation appeared to be improved. Heart action resumed in one and one-half minutes and remained regular and forceful for ten minutes, only to become feeble and ineffective thereafter. Resuscitative measures including electric defibrillation were conducted during the next two and one-half hours. The heart beat then became regular and forceful. The chest was closed and the patient removed to the recovery room. The blood pressure was 120/60.

Two hours postoperatively she had not regained consciousness. She died five hours postoperatively.

Autopsy showed cardiac hypertrophy and extreme dilatation. The heart weighed 430 Gm. Soft, greyish-pink vegetations were present on the free margins of a bicuspid valve. A circular perforation of one cusp was closed by suture. Tension produced by the suture of another perforation had produced a tear in the thin-walled cusp adjacent to the line of repair. Two of the knots had loosened, one in the anterior commissure and a second at the upper margin of the fissure.

Pulmonary congestion was present with atelectasis.

Four thousand cubic centimeters of fluid were present in the peritoneal cavity. Chronic passive congestion of the liver was marked.

Comment.—This case demonstrates the rapid deterioration that occurs following subacute bacterial endocarditis with perforation of a bicuspid aortic valve. Operation was done under desperate circumstances in an attempt to correct a valvular deformity which was incompatible with life.

Congenital Aortic Valvular Stenosis

Aortic valvular stenosis represents about one to two per cent of congenital heart disease.[9,10] It is occasionally associated with other cardiovascular defects, especially patent ductus arteriosus or coarctation of the aorta.[11]

Relatively severe stenosis and obstruction may be present without symptoms.[12,13] Vertigo and syncope are ominous and may portend sudden death. However, sudden death can occur without previous symptoms. Failure is rare.

Physical findings include a systolic thrill accompanying a harsh, widely distributed murmur, diamond-shaped on the phonocardiogram. The murmur and thrill are maximal immediately to the right of the sternum at the first or second interspace. The intensity of the second aortic sound has not proved to be useful in differentiating subvalvular from valvular stenosis. The peripheral pulse and pulse pressure may be small. Arterial tracings show a slow rise to the peak of systole, often with an anacrotic notch or slur, or a double systolic peak.[14] Left ventricular strain or hypertrophy is the characteristic electrocardiographic finding. X-ray and fluoroscopic studies may disclose enlargement of the left ventricle, sometimes

*Dr. Fred Lyon, now a Fellow in Obstetrics and Gynecology at the University of Minnesota Hospitals.

with aortic dilatation and occasionally with a small aortic knob. Calcification of the valve is absent.[15]

In a group of eight patients[13] the cusps were thickened and fused with an average orifice of 8 mm. At times the commissures were irregularly fused with the orifice in an eccentric position. The margins of the cusps were thickened and firm, but in no instance was calcification found.

Indications for surgery include syncope, vertigo, easy fatigability or reduced exercise tolerance, cardiac enlargement, marked left heart strain, a systolic gradient over 50 mm. Hg.[14] across the aortic valve with a normal or decreased cardiac output. Surgical approaches include the transventricular route,[16] direct vision exposure with hypothermia[13] and with a pump-oxygenator.[17]

Case 3. A thirty-seven-year-old farmer's wife was admitted February 12, 1957 to February 27, 1957. She complained of spells of amnesia beginning in January, 1957. Two such attacks lasting ten to fifteen minutes occurred while she was walking but not particularly exerting herself. For two years she had mild pain in the chest with exertion, relieved by rest. During this period she was somewhat breathless on exertion. There was no history of rheumatic fever. In 1940, she had had an appendectomy elsewhere. At that time her blood pressure was 100/80 mm. Hg. A loud systolic murmur and thrill were present at the base of the heart. Heart size and four lead electrocardiogram were normal. The diagnosis was congenital subaortic stenosis.

On examination February 12, 1957, the blood pressure was 110/90 mm. Hg. The heart was not enlarged. There was a systolic thrill at the base. The first sound was effaced by a holosystolic Grade VI murmur all over the precordium. The second sound was clearly heard at the base of the heart. The systolic murmur was maximal over the base but also transmitted throughout the chest and into the neck vessels. Femoral pulses were markedly diminished; pedal and radial pulses, practically absent. Twelve lead electrocardiogram showed changes characteristic of a left strain pattern. Chest x-rays showed slight prominence of the left ventricle, small aortic knob, and no valvular calcification. The electroencephalogram was normal. With the preoperative diagnosis of congenital aortic stenosis, surgery was elected on February 16, 1957.

The chest was entered through a bilateral thoracotomy and transverse sternotomy at the level of the fourth interspaces. The ascending aorta was enlarged and an intense systolic thrill was palpable over the base. Total cardiopulmonary by-pass was performed employing a bubble oxygenator. The aorta was cross-clamped, and the heart arrested with potassium citrate in heparinized blood. Aortotomy was done exposing the aortic valve. Three cusps were evident. The commissures were densely fused, with an orifice of approximately 7 mm. in greatest diameter. No calcification was encountered. With sharp dissection the commissures were accurately developed to the annulus producing an aortic orifice of 2.5 to 3.0 cm. (Fig. 1C). The aortic incision was closed, the cross-clamp removed, and heart action restored.

The patient has been obsrved for two years. She has had no further syncope, angina pectoris, or breathlessness. She is able to do her housework on the farm. She can walk stairs without pain. No thrill is apparent. A Grade I systolic murmur is heard at the base. Blood pressure is 118/90 mm. Hg. A Grade II basal diastolic murmur, high-pitched, is audible at the base. Electrocardiograms continue to show left strain pattern.

Comment.—This is an example of congenital aortic stenosis. The systolic murmur was first found at age nineteen and the symptoms appeared at thirty-five years.

Valvuloplasty under direct vision was done with good restoration of the aortic orifice. Evidence for minimal aortic insufficiency appeared postoperatively. An excellent clinical result was obtained.

Subvalvular Aortic Stenosis

Among forty operations for aortic valve disease, Brock[18] found five subvalvular aortic stenoses and concluded that this condition is more frequent than commonly thought. The mortality of symptomatic congenital aortic stenosis is high.[19] Of seventy-three patients with congenital valvular or subvalvular aortic stenosis, eight expired during an observation period of eight years. Five of these eight patients died suddenly, and all were under sixteen years of age.

Congenital subvalvular aortic stenosis must be differentiated from the acquired or functional type.[20] The latter is the result of long-standing systematic hypertension and is regarded as inoperable because the hypertrophic changes involve the entire left ventricle. Functional subaortic stenosis has two characteristics: onset of symptoms late in life, and evidence of aortic dilatation.[21,22]

Differentiation between valvular and subvalvular aortic stenosis is difficult. Catheter withdrawal curves are helpful but not infallible since the subvalvular chamber may be too small to reflect significant pressure changes.[20] Calcification of the aortic valve area, although not an entirely reliable sign, suggests acquired valvular stenosis. Angiography may assist in the diagnosis. Exposure of the aortic valve appears to be the only reliable way of establishing the pathological anatomy.

Transaortic, direct vision exposure of the aortic valve under hypothermia,[13,23] or with cardiopulmonary by-pass[17] appears to us to be the best surgical approach.

Case 4. A thirty-year-old farmer was admitted April 6, 1959 to April 11, 1959, and again May 25, 1959 to June 14, 1959.

His complaints were attacks of weakness, faintness, and dizziness with exertion, occurring about once a month for five months. He was never unconscious and had never "blacked out." There was no history of rheumatic fever. At age fourteen a murmur was first heard. At that time he had an abscess of the left hip requiring several operations for drainage. This was associated with an undiagnosed febrile illness.

Blood pressure on admission was 116/60 mm. Hg. No cyanosis or clubbing was noted. Neck vessels did not pulsate. The heart was enlarged to the left. A Grade VI murmur at the base replaced the heart tones. It was low in pitch and accompanied by a notable thrill. The murmur was transmitted all over the upper half of the body. There was also a Grade II diastolic murmur suggestive of aortic insufficiency heard at the base. The electrocardiogram showed a left strain pattern. Chest x-ray and fluoroscopy revealed some left ventricular enlargement but no valvular calcification. Direct puncture of the left ventricle revealed a pressure of 155/0 mm. Hg. as compared with simultaneous direct radial artery pressure of 85/45. There was a systolic gradient of 70 mm. The pulse was not remarkable. Phonocardiogram showed a diamond-shaped systolic murmur replacing heart sounds at the base.

The patient returned to the hospital for surgery on May 25, 1959. The physical findings were essentially the same. The transverse diameter of the heart on x-ray had increased by 2 cm. He was digitalized with Digoxin, 2.5 mg. in two days.

With the preoperative diagnosis of congenital aortic stenosis surgery was done on June 3, 1959. The chest was opened through a median sternotomy. The pericardium contained 1,500 ml. of dark blood, a legacy of the previous left ventricular puncture. A rough, intense thrill was palpable over the base of the enlarged ascending aorta. Total cardiopulmonary by-pass was instituted employing a disc oxygenator. The aorta was cross-clamped. Aortotomy brought the aortic valve under direct vision. This was entirely normal. The index finger was passed into the left ventricle encountering the pathology. Approximately 15 mm. below the aortic valve there was a fibrous diaphragm-like structure narrowing the outflow tract to an opening scarcely admitting the finger. The lesion was clearly visualized by retracting the aortic cusps. The operative field continued to be bloody and accordingly the stenosis was relieved with a Brock valvutome, rather than by excision of the subaortic stenotic zone (Fig. 1D). The subaortic opening now readily admitted two fingers. The aortic wound was closed and normal heart action restored. Simultaneous recording of the blood pressure in the radial artery and the left ventricle showed no systolic gradient across the aortic valve.

The postoperative course was favorable and on the eleventh postoperative day the patient was discharged. At the time of discharge from the hospital blood pressure was 110/70 mm. Hg. The systolic murmur was reduced to grade II with no thrill. The diastolic murmur was still present. Peripheral pulses were normal. Three months later he felt well and had started doing some farm work.

Comment.—This is a case of congenital subaortic stenosis. Preoperative direct left ventricular puncture was complicated by hemopericardium. The pathology was discovered only by direct surgical exposure. Technical problems precluded what is probably the ideal management of this lesion, excision of the stenotic area. The method employed resulted in complete removal of the obstructive gradient. The clinical result over a short follow-up has been excellent.

Summary

Four cases of various types of congenital aortic valvular deformities are presented. Problems of diagnosis and medical and surgical management are discussed.

The Treatment of Fractures of the Femoral Shaft

ANTHONY J. BIANCO, JR., M.D.
Rochester, Minnesota

From the Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

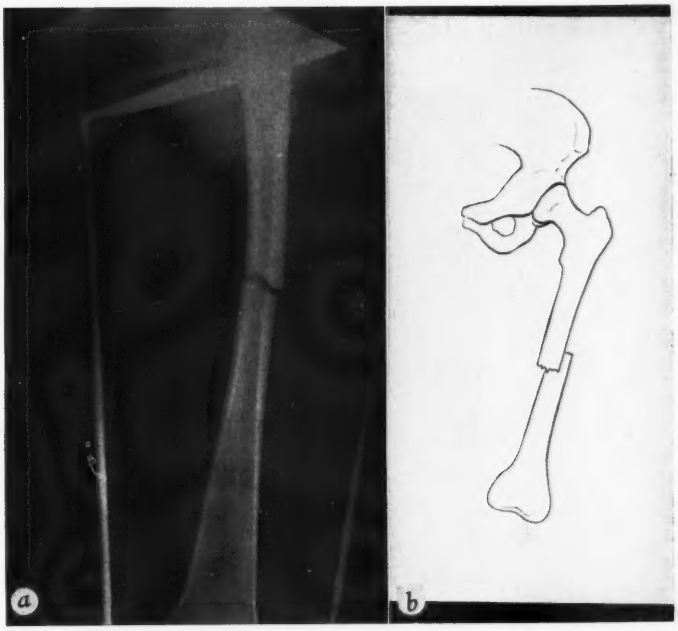

Fig. 1(a) and (b). Transverse fracture of the midshaft of the femur. The ideal type for fixation with an intramedullary nail.

● *Modern gadgetry, in both medicine and other fields, often is not an unmixed blessing. This review emphasizes that such things as intramedullary nails for the repair of femoral fractures often are of great help but may have associated disadvantages and complications when used incorrectly.*

Read at the meeting of the Minnesota Surgical Society, Duluth, July 17, 1959.

THE USE of the intramedullary nail for the treatment of fractures of the femoral shaft did not become practical and extensive until after World War II. As early as 1886,[1] however, several pioneer surgeons had attempted this method, using various materials such as steel rods and ivory and bone pegs, but with only limited success.

As is often the case in surgery, when an attractive, revolutionary and obviously effective surgical procedure is developed for a difficult problem, the procedure is likely to be used indiscriminately. Such has been true of the intramedullary nail in fractures of the femoral shaft.

To quote Hugh Smith: "Given the proper indications, intramedullary fixation is the most effective form of therapy for many fractures of the shaft of the femur." To continue the quotation: "This technique if applied to improperly selected cases or if inefficiently or unskillfully carried out, offers more possibilities of trouble than any other."[2]

I should like to review the indications for and advantages of the intramedullary nail, as well as to emphasize some of its disadvantages, contraindications and the complications inherent in its use.

I should like also to review the older methods of treatment, both closed and open, and to mention

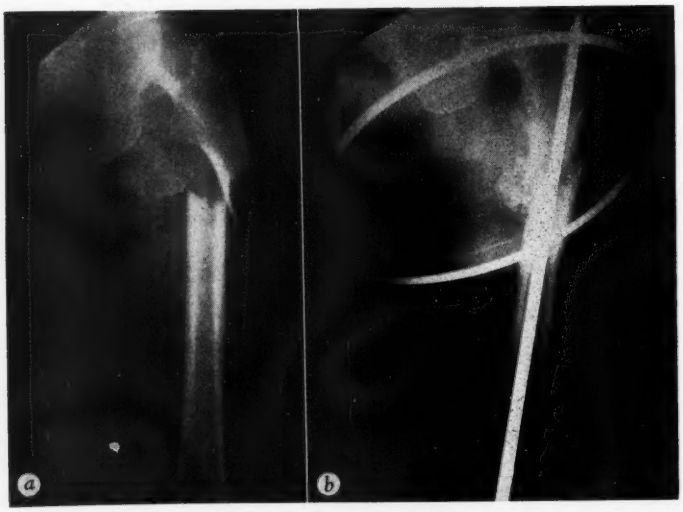

Fig. 2(a) Preoperative and (b) postoperative views of pathologic fracture (adenocarcinoma of breast) of the upper femoral shaft treated with an intramedullary nail. (Bone graft also done at time of operation.)

Fig. 3(a) and (b). Fracture of the lower part of the femoral shaft (two months postoperatively). Note the increasing diameter of the intramedullary canal below this level.

some of the advantages of these methods over the use of the intramedullary nail in fractures of the femoral shaft.

roughly, the middle third of the femoral shaft.

Experienced surgeons are able to expand these limitations somewhat, particularly in the region

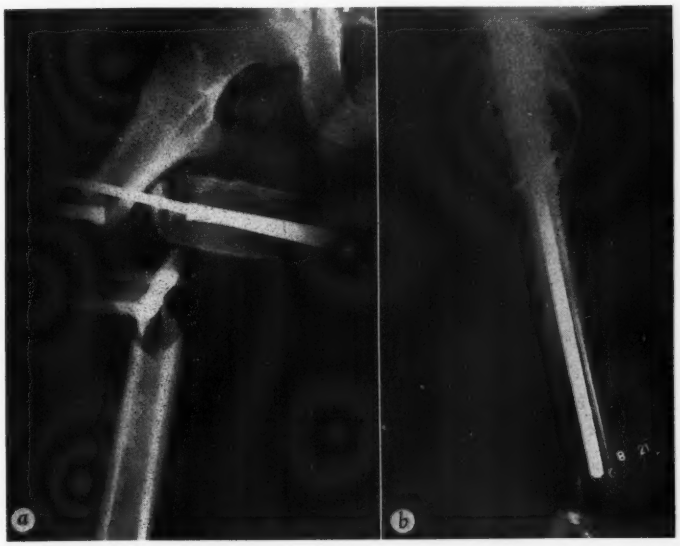

Fig. 4(a) Severely comminuted fracture of the femoral shaft treated with an intramedullary nail. Primary bone grafting of iliac bone also was done at the same procedure. (b) The result four months postoperatively.

Intramedullary Nail

The great advantage of the intramedullary nail is that it provides efficient immobilization of the fracture in anatomical reduction, and yet allows early motion of the hip and knee, and prompt ambulation with weight-bearing on the fractured extremity.

Joint stiffness and muscle wasting therefore are markedly reduced, and long, expensive periods of hospitalization are shortened.

The ideal condition for the intramedullary nail is a fresh, transverse, simple fracture of the middle third part of the femoral shaft in an adult person[1] (Figs. 1*a* and *b*).

Certainly the advantages of the method can be employed in other situations, but the foregoing is the ideal indication.

The intramedullary nail immobilizes effectively by fitting snugly in the intramedullary canal. Obviously, therefore, it should be used only if the intramedullary canal is narrow enough to hold the nail. The intramedullary canal of the femur has been said to fulfill this requirement from a site about 2 inches below the lesser trochanter to a point 7 inches above the adductor tubercle or, of the lesser trochanter (Figs. 2*a* and *b* and 3*a* and *b*). In general, however, limitation of the use of the intramedullary nail to the middle third of the shaft is good practice.

As the age of the patient advances, the diameter of the intramedullary canal increases, sometimes so greatly that a snug fit cannot be obtained with the largest nail.

Use of the intramedullary nail in compound fractures of the femoral shaft should be subject to the same rigid restrictions which are imposed on the use of other internal-fixation devices in compound fractures.

It is far safer to perform the usual primary debridement and closure of the compound wound, immobilize the fractured femur in balanced traction, and await healing of the wound before intramedullary nailing is attempted, than it is to nail the fracture early and invite infection of the entire intramedullary canal.

Sometimes, while waiting for the compound wound to heal, the surgeon is surprised to find that the fracture already has begun to unite under traction, making intramedullary nailing unnecessary.

As mentioned previously, the transverse fracture in the middle third of the shaft is that type in

which the intramedullary nail can be used to greatest advantage. When this nail is fitted snugly, there is little tendency for rotation or shearing to occur at the site of fracture. Early weight-bearing not only can be permitted but should be encouraged to impact the fragments and to stimulate union.

Fig. 5. Fracture of the femoral shaft. The cortex of the distal fragment was split by an intramedullary nail which was too large in diameter for the intramedullary canal.

The intramedullary nail also can be used effectively in some oblique and comminuted fractures of the femur, but here, again, it should be used with rigid restrictions. The advantages of early mobilization and weight-bearing characteristic of the intramedullary nail may not be obtainable after oblique and comminuted fractures, and so early mobilization and weight-bearing should not be allowed (Figs. 4*a* and *b*).

Actually, in this instance the intramedullary nail should be considered no more than an internal splint to permit and maintain anatomical reduction. External immobilization in a plaster spica cast or suspension in a splint in bed is essential for adequate immobilization of the fracture, at least until early union is evident. Failure to recognize this limitation of the intramedullary nail in basically unstable oblique or comminuted fractures has resulted in unnecessary delayed union and nonunion and frequent unjustified criticism of this method of treatment.

In addition to the benefits of its use in fresh fractures, the intramedullary nail has very special advantages in the treatment of pathologic fractures or impending pathologic fractures of the femoral shaft.

Pain usually is well controlled and early ambulation is permitted when the nail is used, thus reducing the possibility of the complications resulting from inactivity.

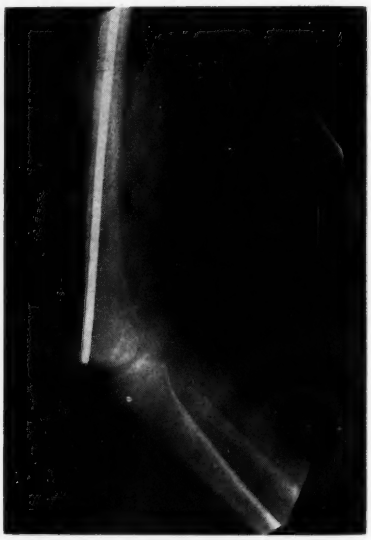

Fig. 6. Penetration of the knee joint by an intramedullary nail of excessive length.

In addition to metastatic lesions of bone from neoplasms of the breast, kidney, prostate and thyroid glands and gastrointestinal tract, lesions of the bone resulting from Paget's disease, hyperparathyroidism and osteogenesis imperfecta can be controlled successfully with the intramedullary nail.[3]

Thus far, no convincing evidence has been advanced that intramedullary nailing increases mechanical dissemination of tumor cells by increasing intramedullary pressure during insertion of the nail.[3]

Moreover, the presence of the intramedullary nail does not appear to reduce the irradiation delivered to a metastatic lesion of the bone, especially if more than one portal of entry for the rays is employed.

Disadvantages and Complications.—The greatest disadvantage to the use of the intramedullary nail is the fact that a surgical procedure is required to insert it. Although this is a disadvantage common to all operative methods, insertion of an intramedullary nail often can be particularly formidable. The closed or so-called blind method of nailing in which the nail is driven down the shaft without exposing the fracture is mentioned here only in passing, and only to condemn it—particularly when the procedure is done under fluoroscopic control.

A few of the reported complications resulting from the "blind" method are as follows: (1) roentgen-ray burns to the hands and face of the surgeon, (2) missing the distal fragment of the fracture with the nail, and (3) damage to the major vessels and nerves of the extremity.[2]

Complications which are peculiar to intramedullary nailing are as follows: (1) improper length and diameter of the nail, (2) cutting out of the cortex or splitting of the cortex by the nail, (3) breaking of the guide pin, (4) additional comminution of the fragments, (5) pain and swelling in the knee, (6) bending or breaking of the nail, (7) bursa formation over the end of the nail, (8) pain in the hip, (9) migration of the nail, and (10) distraction of the fragments (Figs. 5 and 6).[4]

Discussion of the actual operative technique is not within the scope of this presentation. However, most of the complications mentioned above as due to nailing can be prevented if four principles are observed.

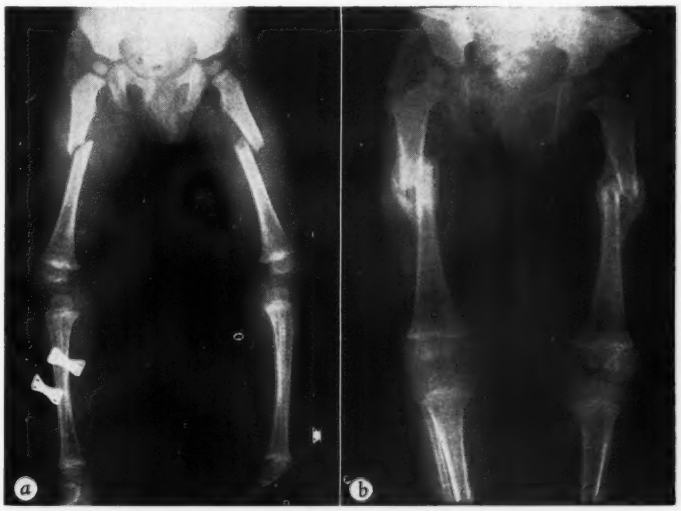

Fig. 7(a) Bilateral femoral fractures in a two-year-old child treated by traction. (b) Note extent of healing six weeks after the time of fracture.

First, open reduction is performed, the nail being carefully inserted into the proximal fragment and then driven into the distal fragment under direct vision.

Second, the proper length and diameter of the nail to be used are determined preoperatively by roentgen-ray measurement, the opposite femur serving as guide.

Third, the intramedullary canal is carefully reamed to the correct size before the nail is inserted.

Fourth, adequate roentgenograms are made during and immediately after insertion of the nail.

Closed Method

The closed method of treatment of fractures of the femoral shaft can be used in many situations in which the use of the intramedullary nail is contraindicated. The closed method consists of manipulation of the fracture into satisfactory position, usually with the use of anesthesia, and then maintenance of reduction with traction in a splint or by the use of a plaster hip spica cast.

However the reduction is maintained, manipulation of the fracture fragments usually must be performed first. In most cases traction alone cannot be expected both to reduce the fracture and to maintain reduction. Therefore, traction should

be considered a method of immobilization and not a method for obtaining reduction.[5]

Indications.—Closed reduction is the method of choice for badly comminuted or unstable oblique fractures, as previously mentioned (Figs. 8*a*, *b*, *c* and *d*).

Fig. 8. Comminuted fracture of the femur in an eighteen-year-old man treated by traction and a plaster hip spica. (a) January 24, 1958. (b) February 3, 1958. (c and d) June 20, 1958. Solid union took place five months after the treatment and the patient returned to work as a farmer.

choice for children, since persistence of open epiphyseal lines in the femurs of young patients prevents use of the nail because of the danger of interference with growth (Figs. 7*a* and *b*).

Closed reduction can be used when the fracture occurs toward either end of the femur, where adequate fixation with an intramedullary nail cannot be obtained.

The closed method, of course, is the one of

The greatest advantage of the closed method, in some respects, is that no open operative interference is required. In the presence of infection or when infection is likely to occur, no other method can compare with the closed method of treatment.

A number of ingenious traction splints have been devised for the fractured femoral shaft, but the Thomas splint with a Pearson knee attach-

ment probably is still the most effective and simplest to use. Traction can be achieved by the use of skin tapes or by a Steinmann pin or heavy

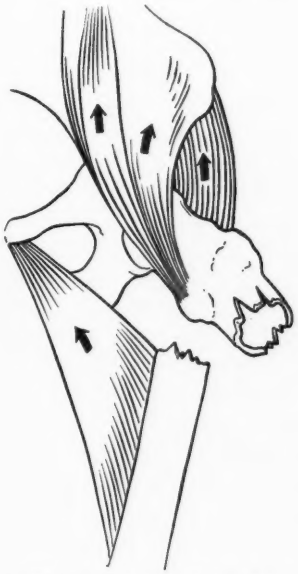

Fig. 9. Subtrochanteric fracture of the femur with displacement caused by muscular contraction.

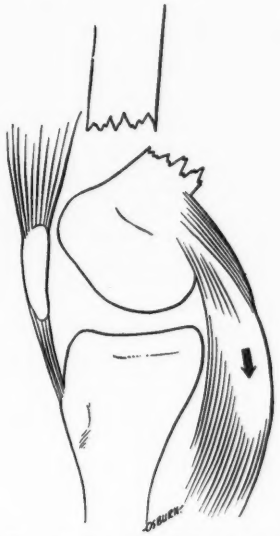

Fig. 11. Supracondylar fracture of the femoral shaft, with displacement.

Kirschner wire passed through the tibial tubercle. Skin traction in general is not so effective as skeletal traction, and cannot be used in the fragile-skinned, elderly patient or when more than ten pounds of traction is required.

Insertion of the skeletal traction device through the distal portion of the femur may damage the quadriceps mechanism and impair motion of the knee, and should be resorted to only in special circumstances, such as in displaced supracondylar fractures.

Disadvantages.—The greatest disadvantage to the closed method, whether it be the traction method or use of the spica cast, is the long time re-

Fig. 10. Healed subtrochanteric fracture treated by fixation with the use of a blade plate.

quired to obtain union of the fracture. Watson-Jones wrote that uninterrupted immobilization should be continued for twelve weeks before clinical and x-ray tests of union are made.[5] During these twelve weeks, however, constant, careful attention must be paid to the immobilized limb and frequent roentgenograms must be taken to be sure angulation has not occurred. Stiffness of the knee joint following four months of immobilization is another definite disadvantage of the closed method. In the young adult or middle-aged patient, however, this stiffness is only temporary and usually subsides completely with the resumption of active exercise. In the elderly patient, some degree of stiffness may be permanent but usually it is not a serious disability.

Other Open Methods

In some fractures of the femoral shaft, open reduction and internal fixation are indicated, yet

Fig. 12. Comminuted supracondylar fracture treated by means of crossed Rush pins and a screw. (a and b) February 17, 1955. (c and d) April 26, 1955.

the rigid prerequisites for use of the intramedullary nail cannot be met. Fractures at the subtrochanteric level are sometimes of this type. They are difficult to reduce and manage in traction because of flexion and abduction of the short proximal fragment. Communition and obliquity of the fracture line and the high level of the fracture may prevent use of the intramedullary nail (Fig. 9).

In such a situation, adequate internal fixation can usually be obtained with any one of several devices, in which a blade or three-flanged nail is inserted into the femoral head and neck and an attached plate is screwed to the shaft, immobilizing the fracture (Fig. 10).

Incidentally, this often-difficult procedure can be greatly facilitated by exposing the fracture with the patient in the lateral decubitus position, instead of supine on a fracture table.

Fractures through the distal third of the femoral shaft and supracondylar region constitute another group in which operative intervention is often necessary, and yet the intramedullary nail cannot be used because a snug fit in the intramedullary canal cannot be obtained (Fig. 11). The use of two intramedullary Rush pins, one inserted medially and one laterally through the femoral condyles, immobilizes transverse or essentially stable fractures at this level once reduction has been obtained (Figs. 12*a, b, c* and *d).*

Oblique or comminuted fractures often may be effectively stabilized with single or multiple screws. Occasionally, use of a plate and multiple screws or Parham bands may be indicated.

These devices should again be considered no more than internal splints. The need for external immobilization in the form of a plaster spica or traction splint cannot be overemphasized if nonunion is to be prevented.

When in doubt as to stability after internal fixation, one should apply a cast or immobilize the limb in a splint in bed until roentgenographic evidence of union occurs, regardless of the type of internal fixation used.

Prophylactic Value of Anticoagulant Therapy in Cerebral Thrombosis

A. BOYD THOMES, M.D.
Clinical Associate Professor of Medicine
University of Minnesota
Minneapolis, Minnesota

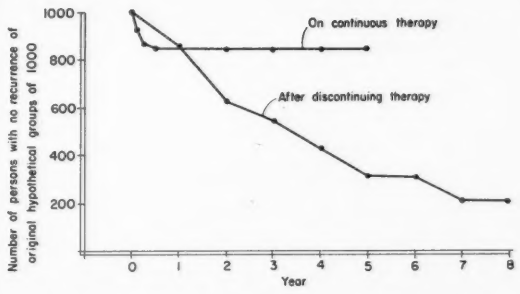

Fig. 1. CVA—First non-fatal recurrence: Number of persons with no recurrence on therapy and number with no recurrence after discontinuing therapy.

THE USE OF anticoagulants in the treatment of cerebral vascular disease has been receiving increasing attention in recent years. Recent reports by Millikan, Siebert and Whisnant,[1] as well as McDevitt, Carter, Gatje, Foley, and Wright[2] have reviewed the experience to date. The former authors have reported favorable results in the elimination of recurring episodes of insufficiency in the vertebral-basilar and carotid arterial systems and have found probable benefit in thrombosis in the vertebral-basilar system with infarction and in actively advancing occlusion of the carotid system. They have, however, suggested the inadvisability of the treatment in "complete" lesions.

The McDevitt group report substantial reduction following the use of anticoagulants in the rate of recurrent thrombosis in a long term study in patients with rheumatic heart disease, hypertensive-arteriosclerotic disease and other miscellaneous conditions.

Fisher[3] has reported similar results in a study of fifty-eight cases, particularly with reference to improvement in transient ischemic attacks. The above studies have been brought together in the report of the second Conference on Cerebral Vascular Diseases.[4]

Materials and Method

The present study is an evaluation of the results of anticoagulant therapy in patients treated in private practice since 1950. The method has been described in detail in a report on the results of anticoagulant therapy in a variety of thromboembolic conditions of which the present group of patients forms a part.[5]

In brief, the method consisted in preparing a code sheet of eighty items on which to record the desired data. These data were then transferred to IBM punch cards for counting and sorting analysis.

The general structure of the study has been to measure the total period of observation for each patient from the date of inclusion in the study. This time period was then subdivided for each case into an initial period called the "duration of continuous treatment" and a succeeding period called the "period of observation after the first discontinuance of treatment."

First non-fatal recurrences while on continuous treatment were recorded on the time scale measuring the duration of continuous treatment. First non-fatal recurrences after discontinuing therapy were recorded on the time scale measuring the period after the first discontinuance. Similar measures of mortality were made.

The rates of first non-fatal recurrence and death on and after discontinuing treatment were determined. The results were then recast into the form of survivorship tables after the method of Hill.[6]

Since no patients had resumptions of therapy in the absence of recurrence, a clear comparison of the incidence of first non-fatal recurrence on treatment can be made with the incidence after discontinuing therapy. Since many of the patients who discontinued therapy had resumptions following a non-fatal recurrence, the group who discontinued treatment may be viewed as being on intermittent therapy. It is possible that these resumptions may have increased the number of survivors in the group who discontinued treatment.

Multiple classification possible.

Anticoagulant therapy was usually started in the hospital, although in some cases it was inaugurated on an out-patient basis. Office prothrombin times were determined as often as appeared to be necessary, usually once every three weeks as treatment became established. The Quick one-stage method was used. A therapeutic prothrombin time was defined as falling between eighteen and thirty-five seconds. The control was almost always twelve seconds or less.

The study consisted in a comparison of the results in a group of fifty-eight patients on continuous

The patients in the discontinued group were observed first on treatment and subsequently after discontinuing treatment. They therefore serve as a control for themselves, as far as sex, age, prior thromboembolic episodes and associated diseases are concerned. A comparison of the never discontinued group (those patients represented only in the treated group) with the discontinued group (those represented in both groups) characterizes the entire sample. To justify the use of the discontinued group as a control, it is necessary to demonstrate that the nineteen patients in the never

[2]Time measured from date of discontinuance of therapy.

of prior thromboembolic conditions, but a smaller incidence of angina pectoris. The incidence of various associated conditions known to have been present at the time of inclusion in the study is listed in Table IV. Again, there is very little difference in the two groups, although the discontinued group has a somewhat higher percentage of cases with hypertension. The above tables suggest that the nineteen cases in the never discontinued group are sufficiently similar to the discontinued group to warrant their inclusion in the treated group as a whole.

Results

In the treated group there were a total of seven first non-fatal recurrences, all occurring during the first six months. Of these, two occurred with a therapeutic prothrombin time and five with a subtherapeutic prothrombin time. In the group who discontinued treatment there were seventeen non-

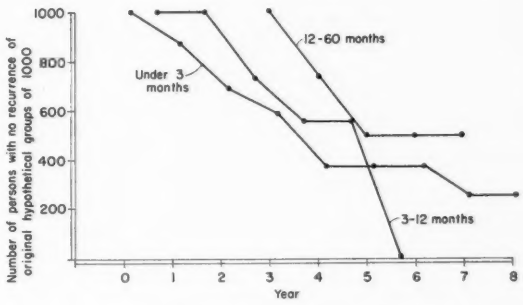

Fig. 2. CVA—Rate of first non-fatal recurrence after discontinuing therapy in persons with different duration of initial treatment (zero to three, three to twelve, twelve to sixty months).

fatal recurrences, with five in the first year after discontinuance and six in the second year.

The incidence of first non-fatal recurrence, on and after discontinuing therapy, is shown in life table form in Table V. The first column indicates the time at which each interval begins. The second column shows the observed percentage with no recurrence during the time interval. The third column presents the ratios from which these percentages were determined. The fifth column shows the estimated number of persons of an original hypothetical group of 1,000 who would have been free of recurrence at the successive times indicated. Figure 1 represents the same data graphically.

In patients on continuous therapy the incidence of recurrence was high during the first month and fell rapidly to zero at the end of six months. It is during this six month period that the recurrences with subtherapeutic prothrombin time were found. Following discontinuance of therapy the incidence of recurrence appeared to be high and to remain high throughout the period of observation.

There has been no useful guide to date as to how long anticoagulant therapy should be continued. To determine whether the recurrence rate after discontinuance is affected by the length of initial treatment, the group was split into those cases who discontinued after different lengths of initial treatment, and the estimated number with no recurrence at successive time periods is shown in Figure 2. The curve for the group with brief treatment (zero to three months) is based on a group of 15.5 cases exposed to the risk of having a

first non-fatal recurrence after discontinuing therapy. The group with intermediate duration of treatment (three to twelve months) is based on

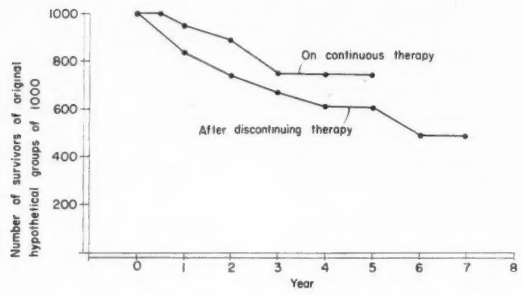

Fig. 3. CVA—Number of survivors on continuous therapy and number of survivors after discontinuing therapy.

nine cases and the group with prolonged treatment (twelve to sixty months) is based on 9.5 cases. After discontinuing therapy the incidence of recurrence was high regardless of the duration of the initial treatment.

TABLE VI. COMPLICATIONS OF TREATMENT

	Number of Patients	%
Severe melena	1	2
Mild hematuria	4	7
Mild ecchymosis	5	9
Mild melena	3	5
Easy bleeding	6	10
Mild hemoptysis	1	2
No complications	46	79

There were three deaths in the treated group, one in each of the first three years. There were thirteen deaths in the discontinued group with six of them occurring in the first year after discontinuing therapy and three in the second year. The incidence of death in patients on continuous treatment and after discontinuing treatment is shown in Figure 3. It is to be recalled that some members of the discontinued group had resumptions of treatment following non-fatal recurrences.

The incidence of hemorrhagic complications is recorded in Table VI. There was only one major hemorrhagic episode and 79 per cent had no complications.

First and subsequent thromboembolic recurrences are itemized in Table VII. There were sixteen deaths in the entire group of which eleven were due to cerebral vascular disease.

Comment

It is to be noted that the recurrences among those on continuous therapy were dated from the onset of the cerebral thrombotic or ischemic episode. The episodes after discontinuing therapy were measured from the date of discontinuance. The first year on continuous therapy was broken into small time units. It is apparent that the tendency to recurrence was strong in the immediate post-thrombotic period, the probability of recurrence being 7.5 per cent in the first month. The next period (one to three months) is two months in duration and the probability of recurrence was 5.5 per cent or 2.75 per cent per month. The third period (three to six months) is three months long and the probability of recurrence was 3.9 per cent or 1.3 per cent per month. Thereafter the observed rate was zero. During the period of hospitalization the prothrombin time was in the therapeutic range about 82 per cent of the time, and after discharge from the hospital the prothrombin time was in the therapeutic range about 72 per cent of the time. Thus it would appear that the large number of recurrences with a subtherapeutic prothrombin time are occurring in a small proportion of the cases and would suggest that more intense early treatment might decrease the incidence of recurrences in the first few months.

TABLE VII. NATURE OF RECURRENCES

	1st Recurrence	2nd Recurrence	3rd or More Recurrences	Total	Per Cent of Total
Myocardial infarct	2	0	1	3	7.7
CVA	19	11	3	33	84.6
Phlebitis	1	0	0	1	2.6
Peripheral thrombosis or embolism	2	0	0	2	5.1
				39	

The plan of the study was such that all people who discontinued therapy became exposed to the risk of having a "first recurrence after discontinuing therapy" as of the date of their discontinuance. The pattern of recurrence in this group is quite different from that noted when they were on continuous therapy, in that the maximal rate does not occur in the early part of the first year. This would suggest that the thrombosis-prone state observed after a thrombotic episode does not obtain in the same degree after a discontinuance of therapy. On the contrary, the rate is higher in the second year than it was in the first.

The subdivision of the discontinued group into those with brief, intermediate, and longer initial periods of treatment does not reveal a tendency for longer initial treatment to lead to a lower subsequent recurrence rate. Although the groups are small, the rates observed are high and rather similar after all three durations of initial treatment. The provisional conclusion would have to be that discontinuance at any time exposes the patient to an increased risk of having another thrombotic episode.

In the first year on therapy, although there were seven non-fatal recurrences, only one patient died. In the first year after discontinuing therapy, there were six deaths and only five non-fatal recurrences. The small ratio of deaths to non-fatal recurrences in the first year on treatment suggests that treatment may reduce the severity of recurrences.

A recent study by Robinson et al[6] has made available an excellent external control against which to judge the present data. The Robinson group, using the life table method of Hill, have provided survival data on a large group of patients after a cerebral thrombosis over a ten-year period. The general composition of their group appears to be sufficiently similar to justify comparison. In studying 535 survivors on whom adequate information was available, they state that an analysis of cumulative recurrences revealed that one-third had recurrences within one year, over one-half had recurrences within two years, and two-thirds had recurrences by the end of four years. The arrest of the tendency to recurrence by anticoagulant therapy as shown in Table V is very impressive in the light of these figures. Since none of our patients had resumptions of therapy in the absence of non-fatal recurrence, it is interesting to note that the recurrence rate after discontinuing therapy is similar to the results in the Robinson study except that the percentage of recurrences in the first year after discontinuing therapy is smaller than would have been expected. This finding suggests that discontinuance of therapy does not, *per se*, predispose patients to a greater likelihood of recurrent thrombosis.

The mortality in the Robinson study reveals that of every 1,000 cases, there would have been about 820 survivors at one year, about 710 at two years, and about 590 at three years. The present study shows the comparable figures for the patients on continuous therapy to be 957, 889, and 752 respectively. The group who discontinued therapy would have had 836, 740, and 667 respectively. These later figures are fairly similar to the Robinson results. It is suggested that some resumptions of therapy after non-fatal recurrences may have benefitted the survival figures in the present discontinued group.

Conclusion

Observations on a group of persons with cerebral thrombosis over several years in private practice would seem to substantiate the value of anticoagulant therapy in preventing subsequent thromboembolic episodes. The data have been brought into the form of survivorship tables for easy comparability of the results at successive dates after the initial episode.

The mortality data, particularly when compared with the results of the Robinson study, suggest a marked reduction in the death rate, particularly in the first and second year after the cerebral episode.

The recurrence rates upon discontinuing therapy after different durations of initial therapy suggest that there is no time when it becomes safe to discontinue anticoagulant therapy. The results suggest that as long as the patient's best interest would be served by avoiding further recurrences, it is probably wise to continue with anticoagulants.

The treatment did not present great problems. Only one major complication was encountered. Despite the fact that many patients had severe hypertension, no instances of intracranial bleeding were encountered.

● *Nasal deformities remaining after satisfactory repair of harelip may loom important psychologically to the patient. This paper describes a technique for the correction of such defects.*

PRESENT-DAY surgical techniques designed to close bilateral clefts of the upper lip effect a satisfactory repair in the majority of cases. However, the child may still be burdened with a deformity of the nose, consisting of a flat nasal tip and a short columella (Fig. 1*a* and *c*). Several procedures for lengthening the columella have been described in the literature. The method selected in each individual case depends somewhat on the initial technique that was employed in the repair of the bilateral cleft. No single operation for lengthening the columella is ideal; each one has its shortcomings.

This presentation describes a technique for lengthening the columella in cases of repaired bilateral cleft of the upper lip; one of us (Erich) has used this method for several years with gratifying results. We realize that this operation is not without fault, but it has given us more satisfactory results than have been obtained by other methods (Fig. 1*b* and *d*).

The technique to be described is not entirely original with us, and it is applicable only to patients whose bilateral cleft lip has been repaired by transferring flaps from the lateral portions of the lip beneath the prolabium, denuded of its vermilion mucosa. Whether it is accomplished in one or two stages, this latter procedure is open to criticism in view of the fact that it produces an elongated upper lip in vertical dimensions. However, this increase in vertical measurements is not altogether undesirable, since it provides tissue for lengthening the columella at the time of secondary repair. The technique described in this paper cannot be used satisfactorily in patients in whom the prolabium forms the full vertical length of the middle third of the upper lip, because there is insufficient skin for advancement to the columella.

The operation to be described is better deferred until the child is four years of age or older. The preschool age of five years is a most opportune time for this type of plastic repair. General anesthesia, with use of an intratracheal airway, is recommended because it eliminates the necessity of infiltrating and distorting the tissues of the upper lip with a local anesthetic agent.

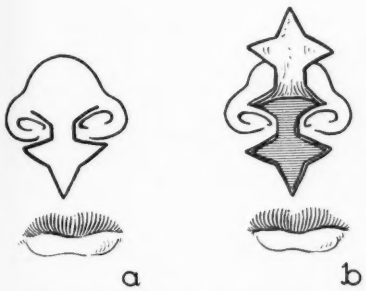

Fig. 2. *a*. Skin flap on upper lip and columella for correction of flat nasal tip due to old repaired bilateral harelip. The stellate part of the flap is outlined in the skin of the premaxilla. The lower dart should not extend to the vermilion border, and the lateral darts are so designed that the height of their bases will equal the amount of columellar lengthening desired. *b*. Entire flap is elevated and retracted upward.

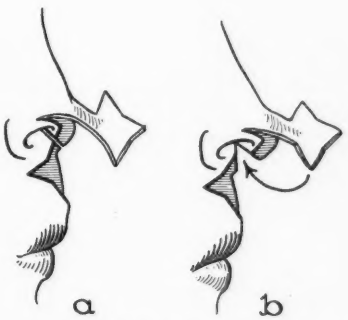

Fig. 3. *a*. Stellate flap retracted upward, exposing membranous septum. An incision is made in the membranous septum at right angles to the cut surface. *b*. Spreading apart incision leaves V-shaped defect into which lateral darts of stellate flaps will be fitted and sutured.

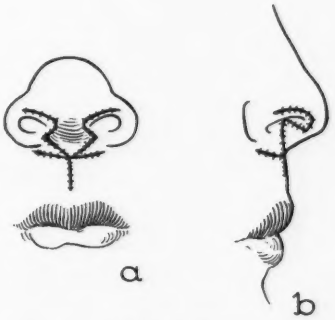

Fig. 4. *a*. Stellate flaps sutured in proper position. The resultant defect at the donor site on the upper lip has been sutured in a T-shaped fashion. *b*. Lateral view of sutured wounds, showing how lateral darts of stellate flap fit into incision in membranous septum.

Surgical Technique

The three-point stellate flap depicted in Figure 2*a* is outlined on the upper lip. The lower dart should not extend to the vermilion border, and the lateral darts should be so designed that the height of their bases will equal the amount of columellar lengthening desired. Using a sharp No. 15 Bard-Parker blade and a scissors, the flap is elevated along with a generous amount of subcutaneous tissue. Subsequently, it is extended upward to include the skin of the columella and the tip of the nose (Fig. 2*b*). Undermining the skin over the lower half of the nose permits exposure of the alar cartilages so that loose areolar tissue between their medial crura can be excised; the alar cartilages then can be approximated and sutured together with catgut, which creates a nasal tip of more normal proportions.

By retracting the stellate flap of skin on the upper lip and columella upward, the cut edge of the membranous septum is exposed (Figs. 2*b* and 3*a*). An incision is made into the membranous septum at right angles to its cut surface; opening up this small incision leaves a V-shaped defect (Fig. 3) into which the lateral darts of the stellate flap are fitted (Figs. 3*b* and 4*b*). Extremely fine silk (5/0 or 6/0) on an atraumatic needle should be employed to suture the flap in proper position. The defect at the donor site on the upper lip is next approximated and sutured (Fig. 4). Closure of the wound as outlined not only lengthens the columella but also reduces the vertical dimensions of the upper lip a trifle. Shortening the upper lip is most desirable, because it had been made abnormally long at the time of primary closure of the cleft.

Summary

A technique for lengthening the columella in cases of repaired bilateral cleft lip has been presented. This method is useful only in those cases in which the lip has been repaired initially by advancing lateral flaps below the prolabium; the technique is not adaptable to cases in which the cleft-lip defect has been closed in such a way that the prolabium forms the entire vertical length of the midportion of the upper lip. By following the steps in the surgical procedure as described, the abnormal flattening of the nasal tip is corrected, the columella is lengthened and the upper lip is shortened, thus greatly improving the facial appearance of the patient.

Malignant Change in a

● *A benign teratoma becomes malignant after twenty-seven years.*

ONE frequently finds it stated in the literature[1-7] that a benign mediastinal teratoma is potentially malignant and, unless promptly removed, will undergo malignant change. The concept of a benign tumor's changing into a malignant one is intriguing, and we can find no documented case that demonstrates this change. Harrington[3] and Fralick and Welsman[7] reported patients who were followed preoperatively by x-ray for four and two years. It was felt that this duration indicated the tumors were at first benign and then became malignant before surgery.

We are reporting here a patient who had partial excision of a teratoma of the mediastinum which was benign on histologic study twenty-seven years before his second operation revealed malignant change in the teratoma.

From the Department of Thoracic Surgery, The Duluth Clinic, Duluth, Minnesota.

Report of Case

In 1920, at age nineteen, the patient had an incision and drainage of a swelling in his neck which led to three aspirations of brown, black and purulent fluid from the mediastinum—followed by three drainages and unroofing operations over the sternum during the next two years. A thick-walled sac was found containing multiple cavities extending from above the sternoclavicular junction downward under the sternum and laterally into the axilla. Because of infection and bone necrosis, two-thirds of the manubrium was rongeured away. Histologic examination of the excised tissues showed an occasional foreign-body giant cell.

He was first admitted to St. Mary's Hospital in Duluth in 1925 for night sweats, chest pain, cough, and blood-streaked sputum. The clinical diagnosis without bacteriologic confirmation was tuberculosis and pleurisy.

In 1928, after having a draining sinus in the sternal region for eight years the right side of his neck became swollen, tender, and painful. A section of sternum was removed by one of us (W.R.B.) to promote better drainage, and an artificial pneumothorax was induced on the

Benign Mediastinal Teratoma

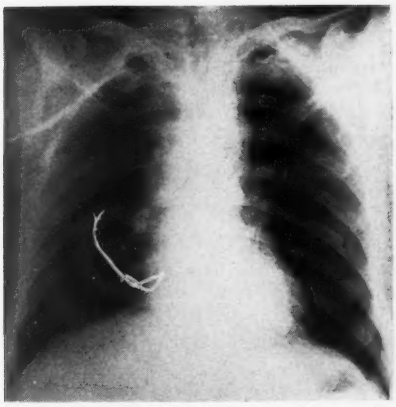

Fig. 2. Radiopaque dye injected into both cephalic veins fails to enter superior vena cava.

JOSIAH FULLER, M.D.
W. C. MARTIN, M.D.
W. R. BAGLEY, M.D.
Duluth, Minnesota

right side in an effort to close a bronchial fistula. This drainage opening was revised on two occasions during the next two years, and a considerable amount of tissue was removed. Histologic examination revealed pancreatic tissue, and the final diagnosis was teratoma of the mediastinum (Fig. 1). Following this, the patient had a persistent drainage from his sternum; however, he was well and working for twenty-seven years.

He was re-admitted to the hospital on November 20, 1956, with a chief complaint of swelling of the neck. Six months prior to admission, the drainage from his sternal sinus appeared to be more purulent. Three months prior to admission, the drainage began to lessen, and eight days before coming to the hospital, he noted a swelling of the veins of the left side of his neck and a sensation of stiffening in his chest. Four days before admission, he had an attack of pleuritic pains in his chest. On physical examination there was distention in the veins on the left side of the neck and in the left upper arm, multiple scars about the anterior chest and over the sternum, and a small sinus in the upper third of the sternum from which exuded a white, watery discharge. Chest x-ray revealed a slight widening of the mediastinal shadow which did not encroach on the esophagus. Injection of contrast material into both cephalic veins in the antecubital fossa showed obstruction of both subclavian veins with no dye visualized in the superior vena cava (Fig. 2). Esophagoscopy and bronchoscopy were negative.

An incision was made through the sternum in the shape of an inverted T, and an attempt was made to reflect the sternal flaps from the mediastinal mass. As anticipated, much dense and fibrous connective tissue was encountered in the mediastinum and in attempting to reflect the sternal flaps, a laceration was made in the superior vena cava at the junction of the innominate veins. This was closed with some difficulty because the veins were enclosed in dense fibrous connective tissue; however, the blood loss was adequately replaced. A frozen section of the excised tissue was reported as undifferentiated carcinoma, and it was apparent then that the fibrosis was a desmoplastic reaction in an extensively invading, highly malignant carcinoma.

Exploratory surgery proved the condition to be hopelessly inoperable because of invasion throughout the mediastinum. Postoperatively, there was evidence of

increased vena cava obstruction, and the patient developed a cellulitis of his incision. This improved on appropriate therapy. On his eighth postoperative day, he was started on palliative deep x-ray therapy to his mediastinum—receiving a total of 300 roentgens. Following this, his condition worsened quite markedly with increased cava obstruction and increased fever. It was apparent that he had developed a thrombophlebitis of his superior vena cava with involvement of the internal jugular veins. His condition continued to deteriorate, he lapsed into coma and died on the thirteenth postoperative day.

Fig. 3. Adenocarcinoma removed from anterior mediastinum, 1956.

Autopsy revealed an extensive malignant mediastinal tumor with occlusion of the superior vena cava and a thrombosis of the right subclavian and left internal jugular veins. There were also metastases from the carcinoma to the right adrenal gland and left supraclavicular nodes.

Discussion

When Figure 1 is compared with Figure 3, it is apparent that the mediastinal teratoma, which contained benign pancreatic tissue on histologic examination in 1929, underwent a malignant change, and twenty-seven years later was an invasive adenocarcinoma. This case gives histologic confirmation to the oft-repeated statement that a teratoma of the mediastinum is potentially a malignant lesion and should be removed when the diagnosis is made. This case also illustrates the hopeless situation that is present once a malignant transformation takes place. In retrospect, it would have been better if we had attempted to make a diagnosis by more simple means, such as removing a supraclavicular node. The venous distention and swelling in the neck prevented adequate palpation in that area. Deep x-ray therapy, in view of the recent infection, was certainly ill-advised.

Summary

A case profile of a patient is presented in which a partial excision of a mediastinal teratoma was performed. Histologic examination of the tumor at that time revealed pancreatic tissue. Twenty-seven years later, this patient died following an unsuccessful attempt to remove this mediastinal tumor, and histologic examination revealed a diffusely-invasive adenocarcinoma of the mediastinum.

Acknowledgment

Localized Brucellosis

Report of a Case with a Retroperitoneal Perisplenic Abscess

C. DU WAYNE SCHMIDT, M.D.

Fig. 2. Roentgenographic appearance of the splenic and hepatic calcification.

● *On rare occasions, brucellosis can give rise to localized visceral suppuration. After ten years of intermittent illness, laparotomy in this patient disclosed a perisplenic abscess caused by brucellosis. Another unusual manifestation of brucellosis in this patient was the presence of calcified splenic granulomas.*

LOCALIZED brucellosis may present one of the most difficult diagnostic problems in clinical medicine. Some of the protean localized manifestations of this disease include spondylitis, meningo-encephalitis, osteomyelitis, septic arthritis, pulmonary granulomas, granulomatous lesions of the liver or spleen, lymphadenitis, pyelonephritis and soft-tissue abscesses.

Localized visceral suppurative changes seldom occur in brucellosis. The medical literature includes cases reported by Eyre and Fawcett,[1] who recorded a subdiaphragmatic and hepatic abscess, Hardy and associates,[2] who wrote of an anterior mediastinal abscess, Tilghman,[3] who is given credit for reporting an abscess of the iliac fossa, Spink and co-workers,[4] who documented a case of pericholecystic and hepatic abscesses, and Gottlieb,[5] who described a case of hepatic abscess with involvement of the abdominal wall and subdiaphragmatic regions.

We recently encountered a patient in whom the diagnosis of brucellosis was substantiated by culture and in whom a retroperitoneal perisplenic abscess was found. To our knowledge, this is the first report of a case with this specific complication.

Report of Case

A 40-year-old white man, who was employed in an Iowa meat-packing plant, came to the Mayo Clinic in August, 1958, for investigation of recurrent episodes of fever, chills and sweats of ten years' duration. In January, 1948, he had lacerated his hand at work; in the following month, he experienced an acute illness lasting about two weeks and characterized by periodic shaking chills, fever (up to 105° F.), soaking sweats and malaise. During this acute illness, he had several studies of the blood and was told he had "Malta fever." Throughout the subsequent year, periodic administration of a vaccine, whose nature was unknown to the patient, was followed by apparent improvement.

In April, 1949, enlargement of a right lower cervical

lymph node had developed. This node subsequently was excised surgically, and the pathologic study was reported as showing necrosis.

During 1950, the patient had begun to have recurrent illnesses three or four times a year; these episodes lasted three to seven days and were characterized by afternoon chilliness, fever (103° to 105° F.), sweats, myalgia, malaise and headaches. Many of the attacks required hospitalization. As a prodrome, he would note loss of energy, which would slowly improve after each attack over a period of two or three weeks. A temporary loss of 10 to 15 pounds usually accompanied each episode despite a continued good appetite. The presence of splenomegaly had been suspected during this period. Between attacks he felt well and worked with zeal.

Since 1956, these attacks had become more brief; however, one in August, 1958, was severe, requiring hospitalization. He had experienced attacks of fever several weeks prior to his visit to the clinic. On the day of his admission, he had noted fever as high as 103° F.

He had received numerous drugs since 1948, including chlortetracycline, penicillin, oxytetracycline, streptomycin, erythromycin and sulfonamides. The longest course of known antibiotic treatment had been given in 1955; it consisted of 500 mg. of oxytetracycline given orally every six hours for at least fifteen days, with 0.5 gm. of dihydrostreptomycin given parenterally three times daily for twelve of the fifteen days. Only questionable benefit had resulted from this regimen. Antibiotics had not been prescribed in the six months prior to his admission to the clinic.

Since the onset of his illness, results of many blood cultures had been negative, but the titer of brucellar agglutinins had been high on numerous occasions (Fig. 1).*

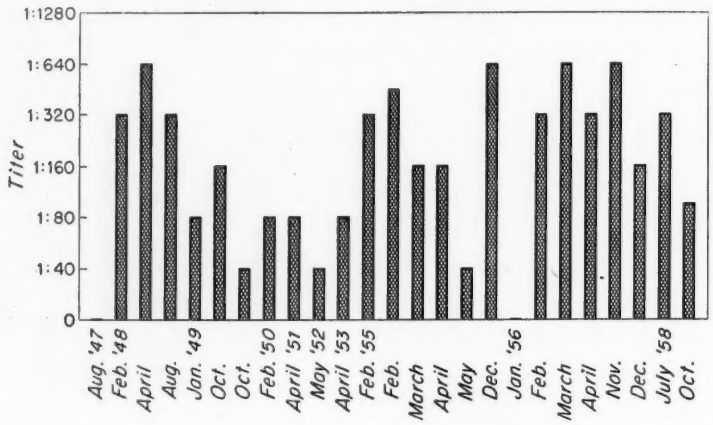

Fig. 1. Results of studies for brucellar agglutinins performed over a period of 10 years.

On admission to the clinic in August, 1958, the patient was a well-developed, healthy-appearing man who was not in any acute distress. The fever, chills and malaise noted earlier on the day of admission had disappeared. He weighed 148 pounds as compared to his usual weight of 155 pounds. His temperature was 99.4° F., and his blood pressure and pulse were within the normal ranges. No lymphadenopathy, hepatosplenomegaly or other significant findings were noted.

Erythrocyte, leukocyte and differential counts were all within normal limits. Study of a blood smear showed normal cellular morphology. Urinalysis likewise gave normal results except for a few granular casts and grade 1 pyuria. The erythrocytic sedimentation rate during the first hour was 32 mm. (Westergren method).

Brucellar agglutinins were present in a titer of 1:100. Three cultures of the blood, as well as one of the urine, failed to give any growth of brucellar organisms. A test of hepatic function showed no retention of sulfobromophthalein after one hour.

Roentgenologic studies of the stomach, gallbladder, thorax and kidneys gave normal results. Roentgenograms of the paranasal sinuses were interpreted as showing thickening of the mucous membrane of the left antrum. Roentgenograms of the abdomen and the lumbar portion of the spinal column showed multiple calcific densities in the splenic region and one in the hepatic zone (Fig. 2).

The patient remained asymptomatic and afebrile, although specific treatment was not given. On the basis of the history and the calcific densities, the diagnosis was considered to be localized brucellosis. He was advised to have abdominal surgical exploration to establish a definite diagnosis, as well as possibly to allow removal of a localized lesion.

Laparotomy in October, 1958, disclosed that the liver and spleen contained many firm nodules about 1 cm. in diameter. The spleen was fixed, being especially adherent to the diaphragm and the posterior parietal peritoneum. When the spleen was freed, a retroperitoneal abscess

*Information was kindly supplied by Drs. J. J. Weyer and Matt G. Sanders, Fort Dodge, Iowa, and Drs. I. H. Books and S. L. Hendricks, of the Iowa State Department of Health, Iowa City, Iowa.

was found that contained about 50 ml. of pus. Splenectomy was accomplished, and the abscess was evacuated. A single lesion was removed from the liver for histologic and bacteriologic examination.

patient was given 750 mg. of tetracycline orally every six hours and 0.5 gm. of equal parts of streptomycin and dihydrostreptomycin (distrycin) parenterally twice daily, starting on the third postoperative day. The objective was four weeks of treatment. He was dismissed two weeks after the operation, having experienced no difficulty except some mild persistent blood-tinged drainage from the surgical wound.

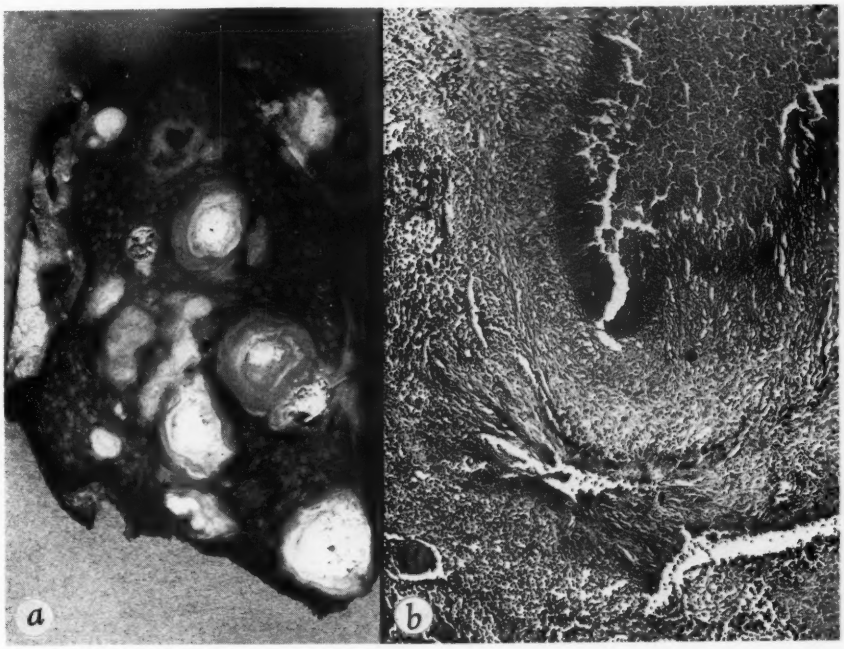

Fig. 3. Splenic brucellosis. (a) Cut surface. (b) Granuloma with necrosis (hematoxylin and eosin; x60).

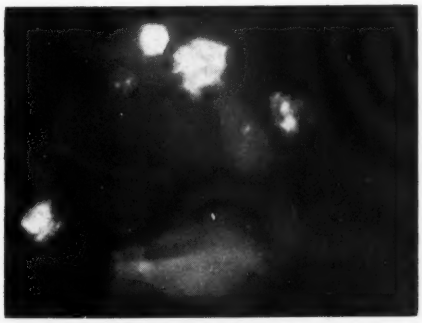

Fig. 4. Roentgenogram of a cross section of the removed spleen, showing small radiating spurs from several nodules.

Pathologic Aspects.—The spleen weighed 233 gm. and contained multiple caseous and calcified granulomas (Fig. 3). These lesions varied from 0.5 to 2.5 cm. in diameter. The specimen from the liver consisted of a solitary, calcified, laminated, caseous granuloma 1.5 cm. in diameter. Cultures of the splenic and hepatic granulomas revealed Brucella suis.

Postoperative Clinical Course.—In view of the surgical findings and the positive results of culture, the

After several days at home, he stopped taking tetracycline because of nausea and upper abdominal distress. He had received these medicaments for a total of two weeks. His personal physician then substituted 500 mg. of novobiocin given orally four times daily; this treatment was continued for two more weeks. The patient was readmitted to our care nineteen days after his previous dismissal because his home physician had obtained both brucellar organisms and staphylococci from the incisional drainage.

After readmission, culture of the drainage from the wound revealed *Staphylococcus aureus* but no brucellar organisms. The drainage tract subsequently was explored surgically, but a recurrent abscess was not found. He was treated further with kanamycin and subsequently had a satisfactory recovery, being dismissed from the hospital early in December, 1958.

Transient drainage from the most recent operative incision occurred for several weeks after his return home, but this subsided without further chemotherapy. He was gaining strength and had no further complications at the time of his last examination, five months after operation.

Comment

The calcific densities noted roentgenologically within the liver and spleen were a significant and interesting finding. Spink,[6] as well as others, pointed out that most patients with brucellosis at some time during their disease have inflammatory lesions in the hepatic parenchyma consisting of focal zones of cellular infiltration. Some of these lesions progress to necrosis or to the formation of granulomas. Splenic enlargement, increased size of the malpighian bodies, infiltration with lymphocytes, the late formation of tuberclelike lesions and other changes may be seen with acute brucellosis.[7] Culture of organisms from splenic tissue in the infected experimental animal has been used as a method of testing the efficacy of new antibiotics. The presence of large granulomas or their calcification within the spleen, however, has seldom been noted clinically.

Recently, three case reports of splenic granulomas, two with calcification, in patients with brucellosis have appeared in the literature.[8-10] Nothing of specific diagnostic value was observed on pathologic examination of the lesions in these cases. In the report of Castleman and Towne,[8] roentgenologic studies revealed large calcific splenic lesions 2 to 3 cm. in diameter showing an irregular outline, with threads of calcium spreading peripherally from a dense nodular center. This calcific pattern is extremely unusual. A roentgenogram of the pathologic specimen in our case showed somewhat more circumscribed nodules, but a number of short spicules were seen projecting from the edge in some lesions (Fig. 4). This characteristic was not prominent in the abdominal roentgenogram (Fig. 2). Other causes of splenic calcification include tuberculosis, histoplasmosis, infarction, hydatid cyst, hematomas and phlebothrombosis.[11]

The recovery of Brucella suis as the etiologic agent in our case confirmed the long-standing clinical impression regarding the cause of the patient's recurrent illnesses. This is the organism most commonly found in association with localized brucellosis.

The patient's relatively low erythrocytic sedimentation rate points out the observation of Spink and associates[4] that brucellosis must be considered when a patient with a chronic febrile illness of doubtful cause has this finding. Our case again emphasizes the observations of Weed and coworkers[12] concerning the important diagnostic value of bacteriologic study of surgically removed granulomas. In this instance, localized brucellosis was associated with systemic manifestations that had been present intermittently for ten years.

Summary

A case of localized brucellosis in a 40-year-old meat packer suffering from recurrent episodes of fever over a ten-year period is presented. Antibiotic therapy during the illness had not been helpful. Variable titers of brucellar agglutinins had been noted, but numerous efforts to culture organisms were unsuccessful until tissue from granulomas in the spleen and liver demonstrated the presence of Brucella suis. Splenectomy and drainage of a perisplenic abscess were followed by antibiotic therapy. The presence of large calcified granulomas within the spleen and a retroperitoneal perisplenic abscess constitutes the unusual manifestations of this patient's disease. Further examination five months after operation revealed satisfactory progress.

Lower Esophageal Ring

A Case Report

From Departments of Surgery and Radiology, Ancker Hospital, St. Paul, and the University of Minnesota, Minneapolis, Minnesota.
Doctor MacLean is a Markle Scholar in Medical Sciences.

JAMES W. LA FAVE, M.D.
S. HARTLEY CALIN, M.D.
LLOYD D. MAC LEAN, M.D.
Saint Paul, Minnesota

Fig. 1. Preoperative roentgenogram in patient, L. M. At surgery the orifice was 3 mm. in diameter. The tip of a nasogastric tube could be felt through the ring by the examining finger inserted into the lower esophagus via a gastrotomy. A hiatal hernia is present.

● *The differentiation of functional dysphagia with some types of organic conditions involving the lower esophagus may be quite difficult. This report of the relatively recently described "lower esophageal ring" illustrates the problems involved. Whether this is a specific entity or merely one of the complications of esophageal hiatal hernia remains to be seen.*

ASYMPTOMATIC, localized areas of constriction of the distal third of the esophagus have been described as an incidental fluoroscopic or radiologic finding.[1] The case reports of Ingelfinger and Kramer[2] and Schatzki and Gary[3,4] in 1953 first illustrated that such constrictions, of a marked degree, could produce symptoms of dysphagia. Though the etiology and the gross and microscopic pathologic anatomy of such constriction rings are poorly understood, the clinical and roentgenologic picture in symptomatic patients is so typical that Schatzki and Gary believe it is a distinct clinical entity which they call "the lower esophageal ring." The following is a case report and a review of the literature concerning the characteristics of this entity and its treatment.

Report of Case

Case L. M. (A-237170).—This sixty-year-old white man was admitted to Ancker Hospital on April 25, 1959 with symptoms of intermittent dysphagia present since September 1957. The dysphagia was a substernal discomfort brought on by ingesting a large bolus of food. Though the symptoms had not been progressive and the patient had maintained his normal weight, he had to restrict his diet to liquids and strained baby food. An upper gastrointestinal roentgen examination demonstrated a localized web-like narrowing of the distal esophagus which partially obstructed the flow of barium (Fig. 1). This deformity was persistent and was observed in all views of the lower esophagus. A small sliding-type

hiatus hernia was also noted. Gastric analysis was performed. Though the tube probably did not enter the stomach, 45 cc. of gastric fluid was recovered and over 100 degrees of free acid was present. Esophagoscopy was refused.

Fig. 2. Postoperative roentgenogram. The hiatal hernia has been repaired and only a slight deformity remains at the site of the lower esophageal ring.

Past History.—A tissue diagnosis of prostatic carcinoma was established following a transurethral resection of the prostate gland in 1956. Since then the patient has been on stilbesterol, 5 mg. daily, and has been without clinical or roentgenological evidence of metastases.

Clinical Course.—Because of the unrelenting nature of the dysphagia, an operation was undertaken on May 22, 1959. An upper abdominal, midline incision was used. There was a small sliding hiatal hernia present. The esophagus was mobilized for a short distance. A gastrotomy was made in the anterior aspect of the fundus of the stomach. Through this an examining finger was passed into the esophagus. Immediately above the esophago-gastric junction a thin, web-like membrane could be felt occluding the esophagus. The occlusion was almost complete, except for an aperature approximately 3 mm. in diameter. With some difficulty the web was ruptured by the examining finger, and the esophageal lumen at this site enlarged to near normal size. The mucosa at the site of constriction was visualized and appeared perfectly normal. The gastrotomy was closed, the hiatus hernia repaired, and a Heineke-Mikulicz pyloroplasty performed. Postoperatively, the patient's recovery was rapid and uneventful. The patient has remained asymptomatic and capable of eating all foods. X-ray studies demonstrate only a slight degree of narrowing at the site of the previous web (Fig. 2).

Comment

It is felt that the above case illustrates many of the typical findings of the symptomatic lower esophageal ring as described in earlier papers.[2-4] Typically, the onset of symptoms occurs after the fifth decade. Men and women are affected with equal frequency. Intermittent dysphagia is the characteristic complaint and may have been present for periods ranging from a few months to several years. The dysphagia is a severe substernal distress produced by ingesting a bolus too large to pass the constriction ring and, characteristically, meat and bread are common offenders. Long, symptom-free intervals may and often do occur as the patient learns to masticate carefully all foods and to avoid those which precipitate difficulty. When this type of regimen is not strictly adhered to, symptoms recur. This would seem to explain the more frequent occurrence of symptoms during periods of emotional stress or tension when the individual may not be so precise about his eating habits. The distress is relieved by passage of the bolus or its regurgitation. If neither occurs, the discomfort may be protracted for hours. Liquids do not produce the dysphagia, but may aid the passage of an obstructing bolus and thereby contribute to the relief of symptoms. More often, liquids will increase the severity of the symptoms if taken after their onset. In spite of severe dysphagia most patients manage to maintain their weight with dietary modifications. In some reported cases the symptoms have progressed but in the majority they have remained relatively constant.

Esophagoscopy usually is negative. The esophageal mucosa appears normal and in only a few instances have the rings been actually visualized.

The roentgenologic characteristics of this lesion have been carefully described by Schatzki and Gary.[3,4] At its distal end the esophagus is seen to be constricted by a localized, smooth, web or diaphragm-like, symmetrical narrowing. This narrowing is usually located 4 to 5.5 cm. above the

(Turn to Page 1607)

(Continued from Page 1602)

diaphragm and forms a sharp right angle with the esophageal wall. The ring averages 2 to 4 mm. in thickness. Sliding hiatus hernias have been demonstrated in almost all reported cases. Fluoroscopically, these rings are difficult to demonstrate unless the esophagus above and below is dilated to a greater diameter than that of the constriction. When these lesions are missed, the patients are frequently labeled as neurotics. Symptoms are directly related to the diameter of the narrowed esophageal lumen as measured on spot films, disregarding the enlargement produced by divergent beams. These narrowings may vary from 3 mm. to 38 mm. in diameter. Patients with large diameter constrictions are usually asymptomatic; those with esophageal rings of 13 mm. in diameter or less are uniformly symptomatic.

The rings act as an area of decreased distensibility. Fluoroscopically, a barium-filled capsule or a food bolus of proper size may be seen to dilate the constriction a few millimeters but no more. A bolus of larger size will be delayed in its passage and thus produce symptoms. The diameter of the ring remains quite constant in most patients. It is striking that even in patients with marked dysphagia and with very narrow rings no dilation of the proximal esophagus is seen.

Associated lesions, other than the aforementioned sliding esophageal hiatus hernias, are not uncommonly encountered. Duodenal ulcer is frequently noted, but in a series of twenty-two cases, three Zenker's diverticula were found also.[4] The significance of these associated lesions, if any, is not clear.

The above features are almost always sufficiently characteristic to distinguish the lower esophageal ring from the longer, irregular, asymmetric constrictions seen with cancer. In achalasia, the area of spastic narrowing is in the most distal esophagus, it is not web-like, and the proximal esophagus is dilated. Peptic esophagitis or chemical, erosive esophagitis produces a cone-shaped narrowing with ulcerations occasionally.

Though the roentgenologic anatomy seems clear-cut, the etiology and pathologic anatomy of this lesion is still unclear. Ingelfinger and Kramer biopsied one ring which demonstrated muscular hypertrophy.[2] Others report a chronic inflammatory cell infiltrate in the submucosa as the only abnormality.[5] Bartlett and Jones feel that these rings consist of esophageal mucosa on the superior surface and gastric mucosa on the inferior surface.[6] They note a chronic inflammatory cell infiltrate in the submucosa between these layers. This finding was present in only one of their patients. A more clearly defined concept of this entity awaits further elucidation of these basic questions.

Most symptomatic patients are simply treated by educating them as to proper selection and mastication of food. For those with small apertures and those few with progressive symptoms, treatment with anti-spasmodic drugs and esophageal dilatation offers no relief, or at best only temporary relief, and surgical intervention is required. A number of procedures have been employed with good results. These include esophagoplasty, excision of the ring around its circumference, excision of segments of the ring, and complete removal of the involved portion of the esophagus with esophageal repair. The most direct procedure, and the one employed in the case reported in this paper, is that described by Bartlett and Jones.[6] It consists merely of performing a gastrotomy through the anterior surface of the gastric fundus and rupturing the ring with the examining finger which is inserted through the gastrotomy up into the esophagus. The gastrotomy is closed and the accompanying hiatus hernia is then repaired.

Summary

A case with a symptomatic lower esophageal ring successfully treated surgically is reported, and the literature concerning the clinical and roentgenologic aspects, as well as treatment, is reviewed. Though the etiology and the pathologic anatomy are poorly understood, the clinical and roentgenologic characteristics of reported cases are strikingly consistent.

Massive
Upper Gastrointestinal Hemorrhage in Pregnancy

Read at the meeting of the Minnesota Obstetrical and Gynecological Society, Duluth, Minnesota, April 25, 1959.

ROGER D. KEMPERS, M.D.
JAMES S. HUNTER, JR., M.D.
RICHARD E. SYMMONDS, M.D.
Rochester, Minnesota

From the Section of Obstetrics and Gynecology and the Section of Surgery, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

THE interesting problems encountered in the recent management of a patient who had massive hemorrhage from the upper part of the gastrointestinal tract complicating pregnancy prompted a search through the files of the Mayo Clinic for other similar cases. Records of the estimated 20,000 pregnancies (not pregnant women) encountered at the clinic from 1945 through 1957 were cross-indexed against possible causes of upper gastrointestinal hemorrhage. Although a sizable group of pregnant patients experienced minimal hematemesis or melena, six patients with massive hemorrhage were discovered, one of whom has been reported on previously by Bowers and Walters.[1] It is the purpose of this paper to review these six cases, directing particular attention to the diverse sources of the bleeding and the alarmingly poor fetal survival.

TABLE I. CAUSE AND FETAL SURVIVAL IN SIX CASES OF MASSIVE UPPER GASTROINTESTINAL HEMORRHAGE ASSOCIATED WITH PREGNANCY

Case	Diagnosis	Fetal Outcome
1	Carcinoma stomach, postgastrectomy bleeding	Stillbirth, 28 weeks
2	Hiatus hernia and pre-eclampsia	Stillbirth, 36 weeks
3	Bleeding gastric artery, no gross ulceration	Stillbirth, 32 weeks
4	Hiatus hernia	Viable, term
5	Esophageal varices	Viable, term
6	Duodenal ulcer	Viable, term

General Background

It is difficult to determine the exact incidence of peptic ulcer in pregnant women, since most peptic ulcers are ameliorated by pregnancy.[2,3] Although it has been estimated[4] that the incidence of peptic ulcer in women of childbearing age is approximately 2 per cent, the incidence in pregnant women is considerably less; indeed, reports indicate that proved active peptic ulcers in pregnant women are rare.[2,5,6]

Aggravation of peptic ulcer in pregnancy does occur and may cause death on rare occasions. Durst and Klieger,[4] in 1955, reported the eighteenth fatal case of peptic ulcer in pregnancy confirmed by necropsy. Vasicka and co-workers,[7] in their recent review of the literature on peptic ulcer in pregnancy, stated that when aggravation or perforation of, or hemorrhage from a peptic ulcer does occur, it is commonly in the last trimester, during labor, or immediately post partum.

Hiatus hernia is thought to appear more fre-

quently in pregnant women than it does in the general population. The general incidence has been reported to range from approximately 1[8] to 9 per cent.[9] However, the reported incidence in unselected series of pregnant women varies from approximately 13[10] to 22 per cent.[11] Little information is to be found on the incidence of hematemesis from this condition in pregnancy, most of the literature being in the form of case reports. Sutherland and co-workers[11] reported four cases of hematemesis, in three of which hospitalization was required, giving an incidence of 20 per cent in their cases of hiatus hernia associated with pregnancy. Harrington[12] stated that hemorrhage is not an uncommon sign in esophageal hiatus hernia, the cause being a traumatic ulcer. He also noted that the hemorrhage may be severe enough to endanger life, while in other instances, the patient is unaware of bleeding and may have severe secondary anemia resulting from occult loss of blood.

Pregnancy associated with bleeding esophageal varices or carcinoma of the stomach must be exceedingly rare if one can judge by the infrequency with which it is mentioned in the literature.

In the infrequent case reports of massive gastrointestinal hemorrhage in pregnancy, the cause of the hemorrhage often remains unknown and the fetus often does not survive. Carangelo and Efstation[13] reported on four patients who had massive gastric hemorrhage, three of whom also had eclampsia. Three of these four women had stillborn infants, the fetal heart tones disappearing after the onset of hematemesis. The three mothers also failed to survive. The cause of the hemorrhage in all cases was obscure. Greeley and Stubenbord[14] reported a case of severe gastric hemorrhage with tarry stools and shock in which the patient recovered after being delivered of a stillborn infant. Subsequent roentgenologic studies of the gastrointestinal tract failed to show a cause for the bleeding. Both of these last two reports noted a case cited by Preiss, in 1907, in which the patient experienced hematemesis with her second and third pregnancies and delivered stillborn infants within 24 hours of the onset of severe gastrointestinal hemorrhage, melena and shock.

Others[15,16] have reported similar examples of massive hemorrhage from peptic ulcer during pregnancy, followed by delivery of stillborn infants. However, similar circumstances also may be followed by delivery of viable infants.[17]

Reports of Cases

Case 1.—A 33-year-old woman, gravida 3 and para 2, gave a history of achlorhydria and, more recently, a gastric ulcer. She recently had been hospitalized elsewhere for pain in the epigastrium and left flank and anemia, for which she had received blood. On admission in April, 1953, examination revealed an intrauterine pregnancy of 25 weeks' gestation, with fetal heart tones present. A roentgenologic diagnosis of an obstructing ulcerating pyloric lesion was made. Subtotal gastrectomy was done for what proved to be grade 4 adenocarcinoma. The postoperative course was uneventful until the sixteenth day, when massive melena and hematemesis developed. The value for hemoglobin was 8.4 gm. per 100 ml. of blood. She was given 2000 ml. of blood. The bleeding, which recurred on the nineteenth postoperative day, could not be controlled without laparotomy and the administration of an additional 4000 ml. of blood. Thereafter, the fetal heart tones disappeared. Spontaneous delivery of a macerated infant occurred eight days after the episode of massive bleeding leading to reoperation.

Case 2.—A 40-year-old woman, gravida 6 and para 4, with one abortion, for several years had noted prolonged episodes of burning epigastric distress, most severe at night and partially relieved by ingestion of water. With the onset of her present pregnancy, the pain had become steadily more severe, with extension to the substernal and lower posterior thoracic region; occasional episodes of mild hematemesis had been noted. Two weeks prior to admission in March, 1950, she had been hospitalized elsewhere because of severe pre-eclampsia. Epigastric pain, massive hematemesis and melena occurred on the day prior to admission. Examination at the clinic revealed a severe degree of pre-eclampsia and an intrauterine pregnancy of 36 weeks' gestation, with fetal heart tones present. The value for hemoglobin was 9.2 gm. She continued to vomit small amounts of blood and, despite the administration of 1000 ml. of blood, the level of hemoglobin decreased to 7.6 gm. On the third day in the hospital, the fetal heart tones were no longer audible. Subsequently, because of the toxemia, amniotomy was done, followed by delivery of a macerated infant. The gastrointestinal bleeding did not recur. Roentgenologic studies later disclosed an esophageal hiatus hernia.

Case 3.—A 20-year-old primigravid patient gave a history of being awakened twice during her pregnancy by severe "heartburn." During the 2 days prior to admission, this had recurred and persisted. She came to the clinic in September, 1958, after three episodes of hematemesis without pain or melena. Examination revealed an intrauterine pregnancy of 32 weeks' gestation, with fetal heart tones present. Her pulse was rapid, and the hemoglobin measured 9.7 gm. All factors in the blood-clotting mechanism were normal. Hematemesis continued on the day of admission, and 1000 ml. of blood was administered. On the following day, 3000 ml. of blood was given because of continuing hematemesis. Although the blood pressure was maintained at relatively normal levels and the value for hemoglobin

remained at 9.7 gm., the fetal heart tones became inaudible. Insertion of a Sengstaken tube, while it stopped the hematemesis, merely served to camouflage the persistent bleeding temporarily, until massive melena appeared. On the third day, despite continuing administration of blood, she was in borderline shock, although the blood pressure remained at an adequate level. It had been thought that she was bleeding from a peptic ulcer and that, in a person of her age, one could expect the bleeding to subside with medical management. However, it was finally apparent that this was a false assumption and that surgical intervention no longer could be delayed. Via a large gastrotomy incision, a single arterial bleeder, unaccompanied by gross surrounding ulceration, was located in the cardia and ligated. Additional blood was given, bringing the total she received to 9000 ml. The following day, a macerated infant was delivered spontaneously, the placenta being small and infarcted. Recovery was uneventful.

Case 4.—A 36-year-old woman, gravida 3 and para 2, had a lifelong history of indigestion and epigastric distress. For two months she had suffered from epigastric burning pain that extended to the back, awakened her at night and was relieved by ingestion of soda or milk. On the day of admission, in November, 1957, she experienced four episodes of massive painless hematemesis and melena. On examination, the pulse was rapid and she appeared anemic. The intrauterine pregnancy was of 38 weeks' gestation, with good fetal heart tones. The value for hemoglobin was 9.7 gm. She was given 1500 ml. of blood. Although active bleeding did not recur, the level of hemoglobin remained at 9.7 gm. on the third hospital day, and an additional 1000 ml. of blood was administered. Mild epigastric pain persisted; she was dismissed on the eighth hospital day, with instructions to follow a strict ulcer program. She subsequently delivered a viable infant and had no further gastrointestinal difficulty. Roentgenologic studies later revealed a large esophageal diaphragmatic hernia.

Case 5.—A 31-year-old woman, gravida 4 and para 3, had been known to have esophageal varices. During the past 10 years, she had experienced 12 episodes of hematemesis and melena, all but two having been associated with pregnancy. The day before admission in April, 1947, she had experienced three bouts of massive hematemesis and had received 1000 ml. of blood at another hospital. When admitted here, she appeared anemic, the value for hemoglobin being 8.2 gm. Physical stigmas suggestive of hepatic disease were absent, but splenomegaly was present. The intrauterine pregnancy was of 5 months' gestation, with fetal heart tones present. Results of liver-function tests were normal, as were the blood-clotting factors. No further evidence of active bleeding occurred. However, on the seventh hospital day, the level of hemoglobin was 5.7 gm., and she received 500 ml. of blood. Roentgenologic investigation confirmed the presence of large esophageal varices, and Banti's syndrome was considered to be the probable basis for the portal hypertension. Splenectomy was deferred. She subsequently was delivered of a viable infant at term and underwent a successful splenectomy and splenorenal venous anastomosis elsewhere.

Case 6.—A 23-year-old primigravid patient described occasional postprandial epigastric distress. For the month prior to admission in February, 1956, she had noticed epigastric pain and backache. She recently had contracted "influenza," followed by bloody diarrhea. The latter, associated with upper abdominal pain, had recurred on the previous day. On admission, she appeared extremely weak and anemic, although not in shock. The intrauterine pregnancy was of 28 weeks' gestation, with fetal heart tones present. Dark blood was present in the rectum. The value for hemoglobin was 4.8 gm. Melena continued and by the fourth day, when the bleeding gradually subsided, the patient had received 4000 ml. of blood. Proctoscopic and roentgenologic studies of the colon and small intestine gave normal results. The patient was dismissed on the fourteenth day. However, subsequent roentgenologic studies revealed a duodenal ulcer, and a routine ulcer regimen was advised. No additional bleeding occurred. The remainder of the pregnancy and the delivery elsewhere were uneventful.

Comment

Table I summarizes the diagnoses and fetal survival in these six cases. In three of the six patients, pregnancy terminated in stillbirths, all shortly after massive gastrointestinal hemorrhage. The causative factor for the fetal deaths cannot be stated with certainty. One patient (case 2), in addition to massive hemorrhage, had severe pre-eclampsia, which undoubtedly affected the fetus. In cases 1 and 3, however, there were massive hemorrhage and borderline shock. Although tolerance to anoxia is present to a greater degree in the newborn infant than it is in the adult, it appears that profound maternal anemia or shock, such as may accompany massive gastrointestinal bleeding, may produce serious effects on the fetus and result in fetal death in utero.

In the afore-mentioned group of 20,000 pregnancies studied at the clinic, a total of 30 were associated with duodenal ulcer proved roentgenologically. Only one of these patients (case 6) experienced massive hemorrhage during pregnancy. Two other patients with duodenal ulcer in this group of 30 had massive gastrointestinal bleeding shortly after delivery, one on her eighth postpartum day and one approximately two months postpartum.

A total of 13 pregnant women had proved esophageal hiatus hernias. All of these were studied, although not necessarily during pregnancy, because of gastrointestinal symptoms. Of this

group, two patients (cases 2 and 4) experienced massive gastrointestinal bleeding while pregnant.

Thus, in our small group of six cases, massive hemorrhage presumably was from hiatus hernia in two instances and from peptic ulcer in one. This correlates well with the reports in the literature, which indicate that aggravation during pregnancy appears more likely for esophageal hiatus hernia than for peptic ulcer.

Bleeding from a peptic ulcer has a tendency to be self-limiting in relatively young patients, such as those with whom we were dealing. This appears to be especially true when the ulceration is associated with a hiatus hernia. Moreover, the exact source of the bleeding is frequently not known. For these reasons, the surgeon is naturally and perhaps justifiably reluctant to operate when the source of bleeding is indeterminate, the fate of the fetus is questionable, and a large pregnant uterus is present to hinder exploration and adequate exposure for what may be a major operative procedure. That this reluctance should be overcome more rapidly in some instances is best indicated by our third patient, who was treated initially by conservative measures that included administration of 6500 ml. of blood. Further observation would have terminated in maternal death in addition to loss of the fetus.

Conservative medical management, with close observation and adequate replacement of blood, rather than immediate surgical treatment, undoubtedly is to be preferred. However, bleeding in these women should be treated even more vigorously than it is in nonpregnant persons to prevent the shock and secondary anemia that jeopardize the fetus, and undue delay should not take place once it becomes apparent that use of transfusions is inadequate treatment. In general, gastrointestinal bleeding in pregnant women should be managed the same as it is in nonpregnant patients. If more than 2000 or 2500 ml. of blood per 24 hours is required to maintain an adequate blood pressure, pulse and hemoglobin, the patient has massive hemorrhage and, in the absence of blood dyscrasia or bleeding tendencies, emergency operation is indicated.

Summary and Conclusions

A study was made of six patients who had massive hemorrhage from the upper part of the gastrointestinal tract during pregnancy. This represented the incidence of this complication in approximately 20,000 pregnancies. The source of such bleeding was diverse. This hemorrhage was most common in association with esophageal hiatus hernia.

In three of these six patients, the pregnancy terminated in a stillbirth shortly after the massive hemorrhage. There were no maternal deaths.

The fetal risk may be diminished by adequate replacement of blood to prevent maternal shock and secondary anemia and by immediate abdominal exploration when it becomes apparent that blood transfusions alone are insufficient to maintain or improve the mother's condition.

Primary Carcinoma of the Fallopian Tube

Case Report

Papanicolaou smears offer a useful method in the diagnosis of the rare primary carcinoma of the Fallopian tube.

MAXWELL M. BARR, M.D.
Minneapolis, Minnesota

Presented as Inaugural Address before the Minneapolis Academy of Medicine, February, 1959.

PRIMARY carcinoma of the Fallopian tube is one of the most malignant and one of the rarest tumors of the female genital tract. The lesion is very rarely diagnosed preoperatively and has a poor five-year survival rate. Such a tumor should be studied as completely as possible.

Renaud[1] in 1847 recorded the first primary carcinoma of the tube. Not until 1888 did Orthmann[2] give the first complete description of the lesion. Barth and Sanger,[3] in 1895, gave the first detailed description and classification which has remained classical today.

Incidence

To date, there are still less than 550 cases reported. Undoubtedly more would have been recorded if the tumors were reported correctly and not mistaken for uterine or ovarian cancer or confused with other pelvic pathology, for example, tuberculosis. Wharton and Krock[4] in 1929 found only five cases of primary carcinoma of the Fallopian tube in 35,000 gynecologic admissions to the Johns Hopkins Hospital. Finn and Javert[5] in 1949 reported six cases in 20,617 gynecologic patients in the Women's Clinic of the New York Hospital, an incidence of one in 4,000. Hu, Taymor, and Hertig[6] in 1959 noted twelve primary carcinomas of the tube in 3,878 primary malignant cases of the female generative tract in 90,611 admissions at the State Hospital for Women, for an incidence of 0.31 per cent of primary malignant tumors at this hospital. Lofgren and Dockerty[7] in a report of sixteen cases had an incidence of 0.16 per cent.

Age Incidence

The average age, according to Wechsler[8] is approximately forty-five years. Lofgren and Dockerty found the age to be 50.9 years with extremes of thirty-four and sixty-five. Hu and associates quoted three cases in the literature at the age of eighteen. Fullerton's[9] oldest patient was eighty

years of age. In regard to parity, in reviewing the literature the impression is that this lesion has been observed just as frequently in nulliparous as in parous women and there has appeared to be no correlation between marital status and family or menstrual history in tumor incidence. Sterility is associated with primary carcinoma of the Fallopian tube and was found in 29 per cent of Hu's series and 44 per cent of Sanger and Barth's, 32 per cent of Curtis's[10] and 30 per cent of Frankel's.[11] Lofgren and Dockerty found nearly 100 per cent incidence of sub-acute chronic inflammatory cases in the portions of the tubes not involved by carcinoma.

Diagnosis

In reviewing the literature, it was found that preoperative diagnosis was seldom made. The symptoms and signs are so protean that this condition is often confused with other common pelvic pathologic entities. A common triad of symptoms is: (1) vaginal discharge, while usually bloody, may be scanty or profuse and either clear fluid or serosanguineous in character, (2) abdominal pain, usually on the affected side, which may be crampy, or sharp to lancinating in character, (3) palpable adnexal mass. The syndrome of abdominal pain that is relieved by or disappears with the concomitant onset of a heavy vaginal flow and sometimes with the disappearance of a pelvic mass has been described as *hydrops tubal profluens*. This condition is rarely observed and is not due to carcinoma, but to the sealing off of the tube in the presence of secretions from the tubal epithelium. Mitchell and Moller[12] quote Hobbs, "In a serous or serosanguineous discharge from the cervix there are to be considered: (1) carcinoma of the uterus, (2) hydrops tubal profluens, and (3) primary carcinoma of the Fallopian tube. In fact, Martztoff[13] considered the serosanguineous discharge, alone, to be pathognomonic of the condition, providing the uterus and vagina are normal.

Brewer and Guderian[14] emphasize the value of the cyto-smear in the detection of carcinoma of the tube in the report of three cases. Others, namely Fidler and Lock,[15] MacLean[16] and Corscaden,[17] and Frankel and Papanicolaou[18] have reported cases of carcinoma of the tube with positive smears. Since the vaginal smear can reflect changes anywhere in the upper genital tract, a positive smear should lead to suspicion of carcinoma of the tube or ovary whenever dilatation and curettage, and cervical biopsies fail to disclose malignancy. Vaginal cytologic studies unquestionably offer the best possibility for preoperative diagnosis of tubal carcinoma.

Brewer suggests culdoscopy or uterosalpingography unless symptoms or findings are present justifying exploratory laparotomy. It is suggested that one lean toward laparatomy in climacteric and post-menopausal women in whom child-bearing functions are not under consideration. Even at the operating table, the correct diagnosis is very difficult since the gross appearance of the affected tube is seldom distinctive. Transection of the removed tube at the time of surgery will permit a correct diagnosis to be made in most instances. In Tatum and Golden's[19] series of seventeen patients, none was diagnosed preoperatively and only three at the time of surgery.

Pathology

Pathologic diagnostic criteria for the establishment of the diagnosis of primary tubal malignancy are: (1) Grossly, the main tumor is in the tube; (2) microscopically:—chiefly, the mucosa should be involved and should show a papillary pattern and (3) if the tubal wall is found to be involved to a great extent, the transition from benign and malignant epithelium should be demonstrable.

Gross Pathology

In advanced cases the gross appearance is quite characteristic. The tube is sausage-shaped, tremendously enlarged, and is simlar to a huge pyosalpinx, except that it lacks the familiar adhesions. The serosal surface is quite smooth while the abdominal orifice of the tube may be either closed or patent. The disease usually arises in the middle or outer third of the tube. When the disease is found in an earlier stage, only a localized nodular enlargement at the involved area may be noted, although there may be dilatation of the tube proximal to this because of the retention of exudate which is often serosanguineous or bloody.

On cross section, the lumen is found to be full of a grayish, granular party-necrotic mass divided by fine septum of connective tissue. In the smaller growths, a vegetative excrescence may be seen in only one segment of the cut lumen. The tubal wall can vary in thickness being normal at times—even in the presence of large growths. Most frequently,

the wall is very thin and often small metastatic growths are present on its external surface.

Microscopic Pathology

The varieties of microscopic classification are numerous. The differences undoubtedly arise from the fact that the group pattern may result in two different forms (papillary and papillary alveolar) with the various gradation or combinations of the two. The most widely accepted classification is that of Sanger and Barth:

Grade I papillary carcinoma: The tumor is confined to the lumen and the transition between normal and malignant tissue is clearly seen. The tumor is well differentiated and the mitosis are infrequent.

Grade II papillary alveolar carcinoma: The tumor shows early glandular formation and there is early invasion of the tubal wall. The individual cells are undifferentiated and there are a moderate number of mitosis.

Grade III alveolar-medullary carcinoma: The tumor shows no papillary projections and the cells are arranged in a medullary or glandular pattern. The cells are poorly differentiated and there is early invasion of lymphatic vessels in the tubal wall. Arthur Hertig, in disagreement with the majority of the writers, found a relatively good correlation between histologic grading and survival of the patient. In Grade III (the most malignant) there were none living—the longest period of survival being twenty-seven months in that group.

Treatment and Prognosis

From reports in the literature, it appears that the surgeon of today is operating on carcinoma of the Fallopian tube earlier and more radically with more favorable results. Hu and his associates report the highest cure rate (40 per cent in a total of twelve cases). Seven patients were treated by supra-vaginal hysterectomy and bilateral salpingo-oöphorectomy, three of whom had postoperative x-rays. One patient deemed inoperable had only a supra-vaginal hysterectomy and some radiation. The remaining four patients were treated with complete hysterectomy and bilateral salpingo-oöphorectomy. All but one had postoperative x-rays. The figures from some other sources are not nearly so favorable. Frankel reported 10 per cent for five-year survival, Lofgren and Dockerty, 16 per cent. Wechsler collected 200 cases in which only six patients survived more than three years. Haupt[20] reviewed 321 cases in 1933 with only six surviving eight years. In a most recent series of seventeen cases, Tatum and Golden presented data supporting their premise that the combination of total hysterectomy and bilateral salpingo-oöphorectomy followed by x-ray radiation offers the best prognosis for the patient with carcinoma of the tube. Six of eight of their patients were living after adequate treatment and only four of nine were alive after adequate treatment. These figures clearly suggest that early diagnosis and radical surgery will increase the cure rate.

The salvage rate can undoubtedly be improved if one follows the measures compiled from the literature:

1. Routine use of cytological smears.
2. Periodic pelvic examinations beginning in the early thirties.
3. Exploratory laparotomy in cases where there is a one-sided mass and the diagnosis is obscure.
4. After carcinoma of the cervix and fundus have been ruled out and there is a persistent uterine bleeding, exploratory laparotomy is justifiable even in the absence of a palpable mass.
5. Careful inspection and, if necessary, frozen section of the tumor at the time of surgery.
6. When diagnosis is clear, adequate surgery and deep x-ray therapy is treatment of choice.

Report of Case

The patient is a sixty-year-old white married woman who was seen in our office for the first time on January 7, 1957. At this time her presenting complaint was spotting for about three months. She stated that she had no discharge or bleeding from menopause at the age of fifty-four until the present illness. The discharge was enough to stain her clothing. There was no odor nor irritation.

Family History.—The father died at age eighty, cause unknown. The mother died at age seventy-two of a stroke. There was no significant family history and no history of accidents or injuries. Illnesses consisted of the usual childhood diseases. She had never been pregnant. There had been no evidence of any pelvic inflammatory disease. Menarche began at the age of fourteen. She had an essentially normal menstrual life. Menses occurred regularly and normally. There was no history of diseases or operations of the female organs. Systemic review was essentially non-contributory.

Pelvic Findings.—The vulva appeared normal. The vagina presented mildly atrophic changes. The cervix showed typical senile changes. Papanicolaou and cervical and vaginal smears were taken. The uterus appeared to be in third degree retroversion and normal in size. The right adnexa appeared to be negative. There was a question of enlargement of the left ovary. This was not certain because of the voluntary rigidity on the part of the patient. She was to return in one week for re-evaluation.

Laboratory Examination at Initial Visit.—Hemoglobin was 14 grams, red count and white count were normal. Sedimentation rate was 19 mm. in one hour. The urinalysis was negative. The Papanicolaou smears later were reported to be negative.

The patient was seen one week later. For the first time blood was visualized in the vagina. Because of the presence of blood, I advised the patient to have a dilatation and curettage.

On January 14, 1957, a D and C was done under general anesthesia. The findings were essentially as noted above. The cystic mass in the region of the left adnexa appeared to be approximately 3 cm. in its greatest diameter. Recto-vaginal examination at the conclusion of the procedure confirmed the vaginal findings. The pathologic report was: endocervical curettings, normal; and endometrium, atrophic. Prior to the D and C, Papanicolaou smears were repeated and reported negative for tumor cells.

The patient was discharged and told to return to the office in one month for a check-up. At this time she stated that she had had no discharge of any type for the past three weeks. She occasionally noted a toothache-like pain in the right lower abdomen. Pelvic findings were essentially unchanged and she was advised to return in two months. She did not return until four months later, at which time she complained of lower abdominal cramps and some bearing-down sensation, mostly in the midline. The uterus felt enlarged to about twice the previous size and seemed somewhat cystic and tense. The left adnexae remained the same in size. The uterus was probed and approximately 20 cc. of bloody fluid came forth. The cervix was dilated. The fluid that was removed was centrifuged. Smears were prepared for cytologic examination. These smears were reported negative for tumor cells. The patient was advised to return in two weeks.

At this time, the uterus felt about half the size it had been before. Smears were repeated and the patient was advised to return in three weeks unless symptoms returned. At her next visit, the uterus was about as it presented a month before, that is, it was distended and globular. The cervix was dilated up to a number 5 Hegar and about 40 to 50 cc. of old bloody fluid was removed. This fluid was then centrifuged and smears were made. These were reported as negative for tumor cells. Incidentally, all the smears that had been taken to this date were reviewed by at least three qualified observers.

Surgical Exploration.—The patient returned ten days later and stated that for the last three or four days she had noticed a brown vaginal discharge. The cervix was closed, but after dilatation approximately 35 cc. of red-brown fluid escaped. At this time, approximately two months after the hematometra, the patient's abdomen was explored with the preoperative diagnosis of possible carcinoma of the Fallopian tube. At surgery, examination of the pelvic contents showed a distended left Fallopian tube that appeared to contain blood. This grossly resembled a left tubal pregnancy. The end of the tube was adherent to the pelvic peritoneum of the left lateral wall. No break in the surface of the tube was seen. The left ovary was adherent to the lateral pelvic wall. The right tube and ovary were adherent to the posterior leaf of the broad ligament on the right by small filmy adhesions. They appeared normal. The uterus appeared normal. Total abdominal hysterectomy and bilateral salpingo-oöphorectomy was performed with removal of generous portions of the broad ligament. Exploration of the peritoneal cavity showed no evidence of metastasis. The hypogastric and aortic nodes were not palpably involved. The pathologist opened the specimen in the operating room. A solid grayish papillary tumor distended the left tube. A portion of this was examined by frozen section and the pathologist made the presumptive diagnosis of carcinoma of the tube.

The pathologic description of the gross specimen is as follows: The diameter of the left tube measured up to 2 cm. at its maximum point. The fimbriated end was thickened, sealed, and on opening the left tube there was a grayish-tan papillary tumor arising from the lining of the tube. The tumor measured 2.5 cm. in length, 1.5 cm. in width, and about 1.5 cm. in depth. The tumor did not appear to extend through the wall but presented itself at the fimbriated end of the tube. The left ovary appeared to be normal. The right tube and ovary appeared to be normal. No evidence of implants were seen on the peritoneal surface of the organs.

Microscopic Section.—Sections of the Fallopian tube confirmed the frozen section impression of papillary adenocarcinoma of the Fallopian tube. The tumor showed fairly well differentiated epithelium in most areas. In other areas, however, there could be seen considerable pleomorphism, loss of polarity, and hyperchromatism of the epithelial cells. In one of the sections there appeared to be invasion of the wall of the tube. No implants on the peritoneal surfaces of the Fallopian tubes or the uterus were observed in the routine sections of the ovaries and uterus showed no evidence of tumor.

Diagnosis.—Papillary adenocarcinoma of the Fallopian tube, primary left.

The patient had an uneventful postoperative course. A question of postoperative x-ray was discussed with several consultants including two x-ray specialists. They felt that since no evidence of extension was found, x-ray therapy should be reserved for a later date should she

develop a recurrence. The patient made several postoperative visits to the office, the last one in November 1958, approximately fourteen months after surgery. At this time she had had no complaints. General physical examination was negative. Pelvic examination was negative. The chest x-ray was negative. Her hemoglobin was 14 gm., sedimentation rate was 20 mm. in one hour, and the urinalysis was negative. This patient's prognosis appears to be good because of the localization of the tumor without gross or palpable spread.

Comment

The case that has been presented was interesting from several aspects. The patient presented the characteristic triad of symptoms: vaginal discharge, palpable mass, and abdominal pain. However, it wasn't until she began to have hematometra that the diagnosis was entertained. I must admit that the diagnosis was made chiefly by the process of elimination. It is interesting to note that numerous vaginal smears were negative and that smears of the fluid from the uterus were negative. Following establishment of the diagnosis postoperatively several cytologic observers were unable to find any carcinoma cells in the slides. The early recognition of primary carcinoma of the Fallopian tube will remain difficult because of the lack of specificity of symptoms and the fact that the lesion is so frequently masked by associated pathological conditions. Although in the case being presented the Papanicolaou smears were negative, there is little question but that cytological smears should offer the best possibility of pre-operative diagnosis. The author disagrees with the use of hysterosalpingography as a diagnostic procedure because of the possibility of dissemination of the cancer. Culdoscopy is of questionable value as an aid in diagnosis because the gross appearance of the affected tube is seldom distinctive. In the Frankel series, the diagnosis could not be made in nine of ten cases at laparotomy and in only three of Tatum's seventeen cases were the diagnosis made at the time of surgery.

Summary

1. Primary carcinoma of the Fallopian tube is a rare gynecologic entity, making up approximately 0.5 per cent of all female genital tract malignancies.

2. A case of primary carcinoma of the Fallopian tube has been presented.

3. The difficulties in diagnosing the disease are discussed.

4. The Papanicolaou vaginal smear used routinely may be of definite aid to early diagnosis.

5. Salvage rate may be improved by early diagnosis and adequate surgery.

Ocular Palsy in Temporal Arteritis

Part III
Neurologic Manifestations of the Arteritides Other Than Temporal Arteritis

C. MILLER FISHER, M.D.
Boston, Massachusetts

INVOLVEMENT of the nervous system in periarteritis nodosa and closely related types takes quite a different form from that encountered in idiopathic arteritis of the aortic arch and its branches (Takayasu's disease) and therefore each will be dealt with separately. In none is there a close resemblance to temporal arteritis.

1. *Periarteritis Nodosa.*—In periarteritis nodosa by far the commonest site of involvement of the nervous system is the peripheral nerves, with the production usually of a multiple asymmetric neuropathy (mononeuritis multiplex) evoked by ischemic necrosis of the nerve bundles. The tibial, median, ulnar and radial nerves are most frequently involved. Lovshin and Kernohan[50] (1948) found a 52 per cent incidence of peripheral neuritis in periarteritis nodosa and in half of these the illness was ushered in by peripheral neuritis. Boyd's[51] (1940) analysis of symptoms showed that, although the number of symptom-combinations in periarteritis nodosa was almost unlimited, a preliminary *febrile episode* and the early appearance of pains resulting from articular and neuro-myositic involvement were characteristic. The neuritis is very variable and may begin abruptly or slowly, and develop in a single nerve or in all extremities. It may appear first or be a late symptom; it can persist, vanish or fluctuate in severity. The upper and lower limbs are affected with equal frequency and in one case motor signs may predominate, in another, sensory signs. Pain, weakness, tenderness of the nerve trunks, hyperesthesia, paresthesias, sensory loss, diminution or loss of tendon reflexes, muscle atrophy and cramps, may occur.

The cranial nerves may be affected also, with the production of an extra-ocular palsy, facial palsy, vertigo, et cetera. Heathfield and Williams[52] (1954) emphasized the approximately symmetrical distribution of the peripheral neuropathy and its tendency to involve chiefly the lower limbs especially the distal parts. Characteristically, their patients had shooting and burning pains in the lower limbs which were worse at night. In almost all cases, sooner or later the lesions of the peripheral nerves form only part of a widespread systemic disease with the characteristic clinical features of periarteritis nodosa—fever, pallor, loss of weight, pain in joints and muscles, weakness, cardio-pulmonary disturbances, abdominal pain, purpuric or ecchymotic areas in the skin, subcutaneous or intracutaneous tender nodules, hypertension, hematuria, and so forth. An exception to this generalization was the case of Kernohan and Woltman[53] (1938) in which a most extensive

Parts I and II appeared in the September and October issues.

arteritic involvement of the peripheral nerves was found and virtually not another lesion elsewhere in the body.

Symptoms and signs of involvement of the central nervous system are not uncommon in periarteritis nodosa and take a variety of forms reflecting the nature of the lesions (infarction, hypertensive hemorrhage, rupture of aneurysm, cerebral edema, et cetera) and their haphazard distribution. Convulsions, hemiplegia, disorientation and confusion are commonest. Occasionally, the picture of subarachnoid hemorrhage or meningitis may be prominent (headache, rigidity of the neck and corresponding cerebrospinal fluid changes). Chorea, blindness, ptosis, ocular palsies, transient attacks of cerebral ischemia, diabetes insipidus and an encephalitis-like state have been reported. Malamud and Foster[54] (1942), in their review of 300 cases of periarteritis reported in the literature, found clinical signs referable to the nervous system in sixty-five cases (21 per cent). The incidence of some of the abnormalities was as follows: generalized convulsions, 8 per cent; organic cerebral syndrome, 4.7 per cent; hemiplegia, 3.7 per cent; cerebellar signs, 3 per cent; increased cerebrospinal fluid protein, 2 per cent; extraocular palsy, 1.7 per cent; increased lymphocytes in the cerebrospinal fluid, 1 per cent; and subarachnoid hemorrhage, 1 per cent. Involvement of the peripheral nervous system was not included in this analysis. Many of these manifestations can be accounted for by the presence of severe hypertension secondary to chronic arteritic lesions of the kidneys, for example, headache, convulsions, intracerebral hemorrhage with subarachnoid extension, papilledema, and impairment of vision.

However, many instances have been reported in which direct involvement of the cerebral vessels by the arteritic process has been demonstrated on pathologic examination, and the following paragraphs briefly summarize most of these cases. Their over-all incidence is low, Rose and Spencer[31] reporting that 3 per cent of cases with lung involvement and 4 per cent of cases without lung involvement, showed brain lesions.

The earliest papers on the subject are often difficult to assess because syphilis may have complicated the picture. Dickson[55] in 1907 summarized the literature up to that time and referred to several cases in which the vessels at the base of the brain or along the spinal cord showed nodular thickening—"hard round grains," "gummatous nodules," "caseating yellow nodules," and the like. For example, the patient of Chvostek and Weichselbaum[56] (1877) had headache, dizziness, vomiting, fever and a right hemiplegia. Pathologically, aneurysms were found on most medium-sized arteries of the body, the cerebral arteries showing some nine aneurysms up to 2 cm. in diameter, one of which had ruptured causing subarachnoid hemorrhage and death. Microscopically, the inflammatory infiltration contained giant cells and the authors attributed the process to syphilis.

Dickson's case was that of a boy aged fourteen and one-half, whose clinical course was marked by hoarseness, abdominal pains, lassitude, fever, repeated convulsions and stiffness of the neck. Pathologically, there were periarteritic nodules on the small and medium-sized arteries of the heart, liver, spleen, kidneys, mesentery, brain and spinal cord; subarchnoid bleeding had occurred from several of the aneurysmal dilatations on the surface of the brain. Microscopically, the lesions showed destruction of the media, and a perivascular infiltration that included numerous giant cells. Asthma was not described, although the arteritic process was granulomatous and the lungs were involved. In Abramow's[57] Case 2 (1899) a student, aged twenty-five, the course was that of chronic nephritis complicated by "neuritis multiplex." Pathologically, nodules were seen along the arteries of many organs and microscopically the cerebral arteries in two sections showed destruction of the wall with perivascular infiltration. Although the author invoked syphilis as the cause, the case was probably one of periarteritis nodosa.

The patient reported by Longcope[58] (1908) ran a seven weeks' course characterized by pains in the joints and calves, malaise, fever, precordial pain, dyspnea, abdominal distention, cardiac enlargement, urinary casts and delirium, especially at night. Autopsy showed multiple peripheral arterial thromboses of renal, hepatic and cerebral arteries. One occipital lobe of the brain showed a soft shriveled yellowish brown infarct and the artery leading to this region was plugged by a firm red and gray thrombus mass. Microscopically the small arteries of the heart, liver, pancreas, testicle, voluntary muscle and brain were involved in an arteritic process. The arterial lesions of the brain must be considered as somewhat equivocal.

The case of Manges and Baehr[59] (1921) was that of a man aged thirty-nine who ran a four months' course characterized by pain in the limbs,

abdominal pain, fever, hematuria, subcutaneous nodules, hypertension and advanced nephritis. Just prior to death the patient had shown several small hard nodules along the right temporal and brachial arteries. Pathologic examination showed healed vascular lesions of the coronary, renal, splenic, splanchnic, bronchial and cranial arteries. There was an aneurysmal expansion of the temporal artery whose walls were extremely degenerated, the media appearing hyaline. The lumen of this aneurysmal sac was occluded by a thrombus of the blood platelet type about two-thirds organized. All signs of inflammation had disappeared and no giant cells were seen. The vertebral artery showed occasional small patches of scarring in the media, the intima was thickened and the internal elastic lamina showed extensive fibrillar degeneration. Only a few small pieces of the intracranial vessels were studied microscopically. The brain showed no gross changes. This is one of the few cases of periarteritis nodosa in which the temporal artery was affected. However, in the formation of an aneurysm the picture was quite unlike temporal arteritis and furthermore no giant cells were found.

Wohlwill's[60] (1923) Case 2 in which seizures had occured along with a multiple neuropathy, showed at post-mortem examination, in addition to a generalized systemic arteritis, multiple areas of encephalomalacia. The small arteries of the basal ganglia and the white matter (not cortex or subarachnoid vessels) were involved in a chronic necrotizing inflammatory process. Giant cells were seen in one focus. The author stated that P. Müller (1899) also found disease of the pial vessels in a case of periarteritis nodosa.

Otani's Case[61] (1924) was that of a woman aged thirty-three with fever, cough, asthma, anorexia, abdominal pain, pains in the limbs and hyperesthesias. The blood eosinophil count was 38 per cent. Pathologically there were typical aneurysms on the arteries of most organs. None was found on the brain vessels but many were seen on the anterior spinal artery and the arteries of the roots and peripheral nerves. Giant cells were found in all medial lesions and were interpreted as a foreign body reaction. This case clearly falls in the granulomatous angiitis group (see below).

In Balo's Case 1[62] (1926), the patient had pains in the limbs, weakness of the lower limbs, uncertain gait, horizontal nystagmus, Babinski signs, fever and incontinence. The duration of the illness was six months. At autopsy there were typical periarteritic nodules on the arteries of the heart and mesentery. The cerebral arteries distal to the first bifurcation of the middle cerebral artery also showed small nodules which often lay in indentations in the brain substance. There were parenchymal softenings in the left basal ganglia, thalamus and cerebellum. A small hemorrhage was found in the left occipito-temporal region. Microscopically the arterial lesions were of all ages varying from acute necrosis to a chronic fibrosing process with sometimes aneurysmal formation.

Weigeldt's[63] (1927) Case 1 was that of a thirty-year-old man who after a two-year course of joint swelling, loss of weight and pains in the limbs, developed a high fever, focal convulsions and signs of meningitis. The cerebrospinal fluid contained 14 to 290 lymphocytes per cu. mm. and 36 mg. per cent of sugar. The blood pressure was 165/100. The meningeal signs gradually cleared but papilledema appeared. The patient died in congestive heart failure five months after the onset of the more acute stage of the illness. Autopsy showed typical periarteritis nodosa with aneurysms on coronary and intestinal arteries. A small area of pigmentation was seen in the arachnoid and dura over the left frontal and right occipital poles of the brain. Histologically the brain vessels showed no evidence of periarteritis. It is possible that in this case an intercurrent intracranial infection complicated periarteritis nodosa and the arteritic process had not extended to the vessels of the neuraxis. Weigeldt's Case 2 was that of a man of thirty-nine who rather suddenly developed a high fever and polyneuritis of both legs. Three months later papilledema appeared and still later a sudden hemiplegia developed. The blood pressure was 108/55. Pathologic study showed periarteritis of the peripheral nerves and of the pial and cerebral cortical vessels. The cause of death was a large intracerebral hemorrhage into the region of the putamen. The general pathological findings were incompletely described and it was not stated if the hemorrhage was of the hypertensive type (the left ventricle of the heart was hypertrophied).

In Case of Bennett and Levine,[64] a man aged seventy-one had pains in the arms and legs and recurrent chills and fever for five months at the end of which time signs of meningitis appeared. The cerebrospinal fluid contained 176 leukocytes per cu. mm. chiefly polymorphonuclear cells. All cultures were negative. Autopsy showed a widespread typical periarteritis with some involvement

of the arteries of the central and peripheral nervous system.

Van Bogaert and associates[65] (1932) described a child with asthenia, headache, pain and weakness of the right lower limbs, nuchal rigidity, vomiting, purpuric spots, diplopia, visual disturbance, torsion movements of the trunk, paresis of the left upper limb, and finally quadriparesis and coma vigil. The cerebrospinal fluid contained blood on several occasions. Biopsy of a skin nodule showed typical periarteritis nodosa but an autopsy was not carried out. The case resembles that of Hampel.

In Case 1 of Hampel[66] (1933), a woman of seventy became progressively more confused in the fourteen days before admission. On examination the only abnormal findings were disorientation and restlessness. The cerebrospinal fluid was bloody and the supernatant fluid was xanthochromic. There were 25 leukocytes per cu. mm. The Wassermann test was negative. Death occurred ten days later and at autopsy all organs were grossly normal except the surface of the brain which showed multiple petechial hemorrhages. Microscopically the medium-sized and smaller pial arteries were ringed with collections of leukocytes chiefly lymphocytes and plasma cells and often giant cells were seen. Many of the small arteries showed necrotizing lesions involving a sector of the vessel wall and occasionally a false aneurysm had resulted. Rarely, the affected vessel was thrombosed and recanalized. Small areas of nerve cell destruction lay adjacent to involved vessels. A few of the cortical penetrating vessels were ringed with small hemorrhages but this was the only abnormality within the brain parenchyma. No bacteria were stained. The remaining viscera were not studied microscopically. This case clearly belongs in the group, granulomatous angiitis with chiefly cerebral involvement. The blood in the cerebrospinal fluid had come from the damaged arteries. The author stated that according to Meyer eight authors previously had found giant cells in periarteritis nodosa.

The case reported by Urechia and Elekes[67] (1934) was of a man aged twenty-three with a six-month history of insomnia, weakness, difficulty walking, shooting pains in the limbs, ataxia of upper limbs, incontinence, mutism and convulsions. The blood pressure was normal. The cerebrospinal fluid contained 7 lymphocytes. The brain, grossly, showed numerous small softenings and at least two hemorrhages. Microscopic examination showed arteritis widespread in pial vessels of brain and cord, in the cortex and white matter of the cerebral hemispheres and in the cerebellum, medulla, spinal cord, spinal ganglia and in the kidney and spleen. The lesions included lymphocytes and giant cells and the walls of the affected vessels sometimes showed a necrotizing process. The authors classified the neurologic symptoms of periarteritis nodosa as polyneuritic, encephalitic, with or without meningitis, encephalomyelitic and psychical.

King[68] (1935), in a typical case, examined an eye enucleated because of acute iritis and secondary glaucoma and found an intense uveitis and retinitis which in the latter was predominant in the arteries and periarterial zones. The author includes references to other papers in which only choroidal lesions were described. Goldstein and Wexler[69] (1937) described the case of a woman aged forty-five with widespread periarteritis whose vision had suddenly become poor in both eyes associated with progressive bilateral optic atrophy. Histologic studies after death showed inflammatory changes in the choroidal and short ciliary vessels but not in the central retinal arteries.

In Case 4 of Kernohan and Woltman,[53] the patient had pain in the right supraorbital, mandibular and oral regions, dizziness, blurring of vision, numbness of the left arm and leg, headache, and finally left hemiplegia and stupor. The blood pressure was 130/50. The cerebrospinal fluid pressure was 360 and the fluid contained 10 lymphocytes and 2 neutrophils per cu. mm., and 30 mg. per cent of protein. Only the brain was examined at autopsy and the walls of the large cerebral arteries were found to be greatly thickened and the lumens almost completely obliterated by subintimal proliferation of connective tissue. Foci of inflammation were scattered along the larger arteries in the subarachnoid space. Neither the intracerebral vessels nor the vertebral-basilar system was involved. The infiltration of cells did not include eosinophils or giant cells. It is possible that this case is one of the rare instances of cerebral arteritis without involvement of arteries elsewhere in the body.

Malamud and Foster[54] (1942) reported a case in which the patient noted, in addition to many other complaints, blurring of vision and diplopia. Examination showed that the right pupil was larger than the left but both reacted normally to light and on accommodation. The medial and inferior rectus muscles were paretic on the right; the superior oblique was weak bilaterally. Nystagmus

was also present. The Kahn reaction of the blood was weakly positive. The cerebrospinal fluid contained 18 to 56 cells per cu. mm. (mostly lymphocytes), and 138 to 174 mg. per cent of protein. A muscle biopsy established the diagnosis of periarteritis nodosa. Pain and paresthesias appeared in the upper extremities, headache continued, and neck stiffness was noted. The gait became stumbling and speech was dysarthric. A left hemiplegia appeared later. The blood pressure was 142/94. There was no eosinophilia. Postmortem study revealed numerous small foci of ischemic infarction disseminated throughout the central nervous system and several infarcts in the kidneys. All the large arteries of the brain and internal organs were normal. Microscopically there was widespread inflammation of the small arteries and arterioles, most severe in the central nervous system and less so in the peripheral nerves, muscles and eighteen other organs.

In Case 5 of Wechsler and Bender[70] (1942), the patient had numbness and an unnatural feeling in the face, tongue and scalp, and the lips felt as if they were burned and swollen. The patient also complained of headache, fleeting backache, and attacks of vertigo associated with vomiting. Autopsy performed at another hospital was reported to have shown periarteritis nodosa of the spinal cord and of the sciatic and obturator nerves. The clinical course of the illness was marked by remissions.

Malamud's[71] (1945) second case of cerebral periarteritis nodosa was not as convincing as his earlier report because of the occurrence of an extremely severe widespread destruction of cerebral tissue with relatively few diseased cerebral arteries. The patient, a boy aged five, after an upper respiratory infection had a series of seizures and became decerebrate. The patient died two and a half months later and the cerebral hemispheres were literally transformed into a liquefied spongy friable tissue resembling milk curds. The cytoarchitecture was completely destroyed. Most of the vessels were normal but on the medial surface of the hemisphere there were a few vessels with a perivascular infiltration of lymphocytes.

Winkleman and Moore[72] (1950) described the case of a man aged sixty-three who suffered from asthma for which he received sulfonamides and penicillin. He then developed pain in the right shoulder, tingling in the fingers and toes, weakness and pain in the limbs, inability to walk, fibrillary tremors, hepatomegaly, hypertension (170/120) and uremia. Along with the arteries in many viscera, the pial vessels showed a typical panarteritic process associated with many small infarcts in the brain. There were also old healed lesions. Evidence of recent and old hemorrhage was found in the subarachnoid space.

Of the seven patients studied by Parker and Kernohan[73] with involvement of the central nervous system manifested early in course of periarteritis nodosa, two had the picture of an acute infectious disease of the brain, three were subject to a chronic illness in which polyneuritis was associated with bulbar or cerebral signs, one showed the picture of a rapidly growing glioma of the brain and the last patient, an elderly man, died of thrombosis of the basilar artery and periarteritis nodosa was a completely unexpected finding. Of the four patients described in detail, three had had convulsions, one had a hemianopia, another developed a sudden hemiplegia after a two-month period of contralateral headache, and one patient had difficulty in speaking. The pathologic data were not given.

Walsh[74] referred to two patients with periarteritis nodosa who developed occlusion of the central retinal artery with optic atrophy, but pathologic studies were not made.

Haft et al.[75] (1957) reported the case of a man, aged forty-four, who suddenly developed signs of a complete spinal cord lesion at the T9 level after a two-week period of numbness, pain and weakness of the lower limbs. The cerebrospinal fluid was grossly bloody and at surgical exploration an extensive hemorrhage compressed the spinal cord from T6 to T9. Postoperatively, the clinical picture of periarteritis developed (anemia, eosinophilia, fever, albuminuria and hypertension) and the nervous system manifestations included: right facial paresis, weakness of the right masseter muscle and the right side of the palate, diplopia on right lateral gaze, nuchal rigidity, Jacksonian seizures, a left medial rectus palsy, deafness on the right side, nystagmus on left lateral gaze and visual impairment in the left eye.

Pathologic examination showed a most extensive distribution of arteritic lesions throughout all organs. There were three hemorrhages into brain parenchyma. The walls of the leptomeningeal vessels were fibrosed and their lumens were occluded. The spinal cord was reduced to a dark brown collapsed band in the region of the operation. One

small spinal leptomeningeal artery showed fibrinoid necrosis of its wall. The source of the bleeding was not identified but apparently it stemmed from an arteritic lesion.

In other cases of periarteritis nodosa there has been asymptomatic involvement of the nervous system. In Case 5 of Kernohan and Woltman,[63] there were no neurologic complaints but the cerebrospinal fluid contained 19 lymphocytes and 4 neutrophils per cubic millimeter, and the pressure was 200 mm. of water. At autopsy there were no parenchymal changes in the brain but some of the arteries deep in the sulci of the brain showed a chronic periarteritis. In Wechsler and Bender's[70] Case 6, "microscopically the vessels in the brain showed thickenings and changes in the adventitia suggestive of periarteritis nodosa." In Cabot Case No. 43411, Massachusetts General Hospital,[76] a woman aged thirty-nine with fever, pain in muscles and joints, and petechiae in the skin died suddenly. There were lesions typical of periarteritis in many organs and a single inflammatory focus was found in the brain sections.

The literature contains several further cases which, although quite atypical, are often referred to. Maxwell and Maxson[77] (1941) reported the case of a ten-year-old child who rather suddenly developed pain and blindness in the right eye, numbness of both hands, maniacal behavior, and coma. The spinal fluid was bloody. The blood pressure was 118/68. The patient died twenty-five days after admission. At autopsy the essential lesions were limited to the cerebral arteries, many branches of the middle, anterior and posterior cerebral arteries being occluded by firm gray thrombi; multiple small gray, raised, aneurysm-like bodies lay scattered along the surface of the arteries. The larger cerebral vessels at the base showed no gross lesions. A small hemorrhage lay in the posterior limb of the internal capsule on the right side. The superior longitudinal sinus was thrombosed. Histologic examination of the gray nodules lying on the arteries showed zones of necrosis and polymorphonuclear infiltration. There was no evidence of organization in the thrombi and no inflammation could be seen in the meninges. The remainder of the organs and vessels of the body were normal except for the lungs which showed several small subpleural abscesses. The illustration of the lesions is not very clear. The case is so unusual that one hesitates to include it in the group of arteritides.

In Richardson's[78] (1928) case, the patient developed facial paralysis, ataxia of gait and dysarthria. Examination showed cerebellar ataxia of the arms and legs, dilatation of the left pupil, confusion, visual hallucinations, pseudo-bulbar spasms of laughing and crying and decreased sensation for pinprick and temperature below the first lumbar level. The cerebrospinal fluid contained 426 cells. There was little or no evidence of systemic involvement throughout the course of the patient's illness which ran fifteen months, finally ending in paraplegia. Pathologically, the vessels of the nervous system were grossly normal. Scattered lesions were seen in the white matter of the hemispheres. Microscopically there were widespread vascular lesions of the cauda equina, spinal cord, medulla, and to a much lesser extent of the basal ganglia and cerebral white matter. The pial vessels over the cortex showed typical lesions but the intracortical vessels were not involved. The striking features of the vascular lesions were medial necrosis and an abundance of foreign-body giant-cells in the adventitial inflammatory infiltration. Lesions predominated in the cauda equina and spinal cord. No reference is made to the findings in the rest of the body but, in view of the abundance of giant cells in the lesions, the case would easily fall within the group of granulomatous arteritides to be described below.

In the case reported by Runge and Melzer[79] (1930), a man aged sixty-one over a four-year period developed bilateral facial weakness, weakness of the tongue, severe dysarthria, athetotic movements, changing tonus in limbs, pyramidal signs and possibly a hemianopia. The cerebrospinal fluid was normal (4 leukocytes). At autopsy, there was a most striking and unusual subintimal connective tissue thickening of the arteries of the kidney, heart and brain. Organizing thrombus was common. The media of the involved vessels showed mild foci of damage, the injured tissue being replaced by connective tissue scar. Despite the advanced arterial changes, nowhere was there evidence of perivascular inflammation and the authors after considerable discussion decided that the lesions represented the healing stage of periarteritis nodosa. However, many of the thrombi appeared to have formed recently.

In Lemke's Case 2[80] (1923) the clinical course (not fully described) was marked by weakness, bilateral Babinski signs, spastic gait and temporal pallor of the optic discs. Autopsy showed micro-

scopic periarteritic lesions of the kidney and brain. In the latter there were foci of perivascular leukocytes but no medial lesions were seen. The parenchymal lesions were typical of multiple sclerosis.

Recently, Treip and Porter[81] (1957) described a most unusual case in which a youth of nineteen progressively developed over a period of twenty months memory defect, unsteadiness of gait, clumsiness, optic atrophy, coma and decerebrate rigidity ending in death. The blood pressure was 190/130. Pathologically many areas of softening were found in the superficial cerebrum and cerebellum, the basal ganglia and brain stem being spared. Microscopically the arteries of the subarachnoid space, heart, spleen, kidneys, adrenals, tongue, testes and portal tracts showed extensive intimal thickening and striking widespread vascular occlusion by recanalized plugs. Nowhere was there any evidence of inflammation and the authors considered the illness to be the late stage of either thromboangiitis obliterans or polyarteritis nodosa.

In summary, the cerebral arteries apparently are not commonly affected in periarteritis nodosa; when they are, the clinical picture reflects the widespread distribution of multiple small lesions, rather than presenting a gross focal neurologic deficit as in most stroke cases associated with atherosclerotic vascular disease. Occlusion of small arteries results in tiny areas of ischemic necrosis and any level of the neuraxis, cerebrum, brain stem or spinal cord may be involved. Hemorrhage from inflamed vessels appears to be extremely rare. Systemic disease was evident in all but a few instances (for example, Case 1 of Kernohan and Woltman). It should be emphasized that in only one of the cases summarized was there involvement of the temporal artery or the larger vessels arising from the arch of the aorta (case of Manges and Baehr) and in that case the lesion did not resemble temporal arteritis.

2. *Allergic Granulomatous Angiitis.*—A short time after Churg and Strauss[29] set this type of periarteritis apart as a distinct pathologic form of arteritis, Newman and Wolf[82] (1952) described two cases in which the central nervous system was involved. In their Case 1, paraplegia was present clinically and the patient died six weeks from the onset of his illness. Pathologically, widespread granulomatous lesions with epithelioid cells, giant cells and lymphocytes involved the vessels of the entire neuraxis; however, only the nervous system was examined at autopsy. This case illustrates the difficulties of classification, for the patient had neither asthma nor hypereosinophilia. In Case 2 the patient, an elderly man with asthma for thirty years, developed, over a period of two and a half years, headache, right amaurosis and signs of a peripheral neuropathy and cauda equina lesion. The cerebrospinal fluid contained 55 to 472 white cells (chiefly lymphocytes) and 98-160 mg. per cent of protein. General pathologic examination showed a disseminated vasculitis which was striking in the lungs and testes. The lower part of the spinal cord, the only nervous tissue available for examination, also showed a giant cell arteritis. Significant hypereosinophilia had not been present in life. It is of interest that biopsy of a maculo-papular skin lesion had been reported as "tuberculoid granuloma" (see sarcoidosis below). It is unfortunate that in Case 1 the rest of the body was not examined pathologically and that in Case 2 the lower spinal cord was the only part of the nervous system available. This was not the first description of this type of arteritis to be reported, for the cases of Chvostek and Weichselbaum, Dickson, Otani, Richardson, Hampel and Urechia and Elekes, already referred to, readily fall in this category.

Recently, several additional cases of granulomatous angiitis involving the nervous system have been reported. The first was Cabot Case No. 41152, Massachusetts General Hospital,[83] in which a sixty-four-year-old man had transient diplopia for a few days, one month before admission. Two weeks later he developed headache and confusion and had two generalized seizures. Examination revealed confusion, perseveration, visual impairment, rigidity of all limbs, a Babinski sign on the left and arterial hypertension (190/120). The cerebrospinal fluid, under a pressure of 240 mm. of water, was slightly xanthrochromic and contained 200 mg. per cent of protein and 55 leukocytes per cu. mm. of which 48 were lymphocytes. The patient developed signs of bilateral cerebral disease and rapidly went into coma and died about one week after admission to the hospital. Pathologic examination showed a widespread necrotizing granulomatous angiitis of the small intracerebral arterioles and also an extensive granulomatous exudate in the subarachnoid space. A perivascular cuff of lymphocytes surrounded many venules. There was no involvement of arteries elsewhere in the body save for one renal arteriole which showed

a mild inflammatory infiltration including two giant cells, a picture similar to that found in the brain.

Two cases were presented before the American Association of Neuropathologists in June 1957 by Neubeurger.[84]. The first was a woman aged fifty-two admitted with a three day history of headache, chills and fever and having had a convulsion the day before admission. She became somnolent and developed a left hemiplegia. An exploratory craniotomy was negative and thereafter the patient slowly deteriorated clinically with aphasia and progressive weakness, dying nine and a half months from the onset of the illness. The cerebrospinal fluid contained 40 leukocytes per cu. mm., chiefly lymphocytes, 110 mg. per cent of protein and 76 mg. per cent of sugar. The general autopsy findings were not remarkable except for thickening of the wall and narrowing of the lumen of the left subclavian and axillary arteries. The large cerebral vessels appeared normal but the smaller ones showed a segmental grayish white thickening and on section the brain showed widely disseminated small recent and old cysts and infarcts measuring up to 2.5 cm. in diameter. The involved cerebral vessels lying in the subarachnoid space showed a striking concentric or eccentric intimal thickening narrowing the lumen. The media was extensively damaged in many regions and the accompanying inflammatory exudate included lymphocytes, phagocytes and multinucleated giant cells. The intracerebral vessels were not affected. Unfortunately the diseased subclavian and axillary vessels were not studied microscopically and the report of the general microscopic findings was not given. This case is difficult to classify especially if it is assumed that the subclavian artery was the site of a giant-cell arteritis and that no other systemic arteries were involved. A faint resemblance to Takayasu's disease might be claimed but the scanty involvement of the aortic arch vessels and the emphasis on intracranial lesions would be highly atypical features. Widespread subintimal thickening and mesarteritis of the meningeal arteries have never been clearly reported in temporal arteritis, so that any link with that disease cannot be very strong. The case is here classed under granulomatous angiitis although the failure to involve intracerebral arteries is unusual, being reported only in Richardson's case.[78]

Neubeurger's second case was that of a woman aged fifty-five who was found unconscious, having been previously well and who died three days later. The cerebrospinal fluid contained 55 lymphocytes per cu. mm., 84 mg. per cent of sugar and 130 mg. per cent of protein. The blood pressure was 150/90. Pathologic examination showed numerous minute petechial hemorrhages scattered over the leptomeninges and cerebral cortex. The arteries of the meninges and cortex showed destructive lesions of their walls and were surrounded by dense collars of lymphocytes and multinucleated giant cells. The general pathologic examination was grossly normal but the microscopic studies were not reported. This case is quite similar to Cabot Case No. 41152.[83]

Two further cases were reported by Cravioto and Feigin[85] in 1958. Their first case was that of a man aged fifty-six who, over a period of two and a half years, ran a gradual downhill course marked by the progressive appearance of intermittent vomiting, transient visual disturbances, papilledema in one eye, optic atrophy in the other, Rombergism, transient aphasia, focal seizures, weakness of the legs, a right hemiplegia, stupor and finally death from intractable seizures. The cerebrospinal fluid contained 88 mg. per cent protein. The electroencephalogram was diffusely abnormal. There was little or no evidence of involvement of the body other than the nervous system, and the patient did not have asthma. Postmortem examination which was limited to the nervous system showed perivascular granulomatous collections both within the parenchyma of the brain and in the subarachnoid space, containing lymphocytes and giant cells. While the walls of many small arteries were severely damaged, the exudate often surrounded rather normal appearing vessels and extended diffusely through the subarachnoid space; at times veins appeared to be involved in the granulomatous process. The brain showed multiple small infarcts and focal astrocytosis.

In Case 2, the patient, a young man aged eighteen, died after six weeks characterized by headache, weakness, drowsiness, numbness of the extremities, bilateral hemiplegia, blurred vision, ptosis, dysphagia, bilateral Babinski signs and finally a quadriparesis. The patient did not have asthma. A complete postmortem study showed a giant-cell granulomatous angiitis of liver, lungs, heart, gastro-intestinal tract and brain. The brain was grossly normal aside from mild thickening of the pia-arachnoid on the anterior surface of the brain stem. A few small hemorrhages were found here

and there through the brain, in addition to small infarcts, one of which was a most striking medial medullary lesion. Again the vessels within the parenchyma and in the subarachnoid space were ringed with a giant-cell granulomatous exudate and in places the arterial wall was necrotic or disrupted.

An unpublished case of this disease was studied pathologically at the Massachusetts General Hospital by Dr. Charles Kubik in 1935.

Case 6.—A woman, aged fifty-two, had noted fatigue, increasing lethargy, loss of ambition and disincliniation to engage in her usual activities for two or three weeks before admission to the hospital. On examination, the only abnormality was questionable papilledema bilaterally. The cerebrospinal fluid was under normal pressure. The total protein was 74, the sugar 65 each in mg. per cent. The Wassermann test was negative in the blood. A urinalysis was normal and the blood pressure was 150/100. Within six days the patient became comatose without any definite localizing or lateralizing neurologic signs. Fluid obtained by ventricular puncture revealed, on the right, 3 leukocytes and on the left, 8; 10 mg. per cent total protein on the right, 36 mg. on the left. There were no signs of generalized involvement of the body.

Only the brain was examined pathologically and grossly it appeared normal. A granulomatous inflammatory process affected the arteries of every part examined, meninges, cerebral cortex, basal ganglia, brain stem, cerebellum and choroid plexuses. Lymphocytes, plasma cells, epithelioid cells and abundant giant cells surrounded vessels and extended widely in the subarachnoid space. Of the countless vessels ringed with exudate only a few showed frank necrosis. The larger arteries were almost invariably intact but the walls of the smaller intracerebral arteries (30-60 u) were indistinct and distorted, the endothelium swollen and the lumens of the vessels difficult to identify. The extent of the granulomatous process seemed to be clearly out of proportion to the signs of vascular damage. There was scarcely any reaction in nervous tissue proper.

In another somewhat similar case seen in 1954 at the Massachusetts General Hospital, the diagnosis was established by biopsy of cerebellar tissue removed at operation.

Case 7.—The patient, a man aged fifty-one, had had a "drunken feeling while walking" and attacks of vertigo for about nine months and transient diplopia for seven months. For six months speech was slightly indistinct, the tongue felt big, his head had a full feeling and he had a tendency to veer while walking. For two and a half months increasing deafness had been noted in the right ear associated with a whistling tinnitus. On examination there were horizontal nystagmus on gaze to the left, vertical diplopia on testing with a red glass, complete deafness of the right ear, unsteady gait, mild cerebellar ataxia of the limbs bilaterally and slurred speech. The blood pressure was 140/80. The cerebrospinal fluid was under a pressure of 140 and contained 166 mg. per cent of protein and 40 leukocytes per cu. mm. A pneumoencephalogram was normal. The posterior fossa was explored and all structures appeared normal grossly. Biopsy of cerebellar tissue showed a granulomatous exudate in the subarachnoid space with extension into the parenchyma along small blood vessels. Large accumulations of lymphocytes surrounded proliferated epithelioid cells and rare multinucleated giant cells were present. There was no caseation necrosis and neither tubercle bacilli nor fungi were found with special stains.

Extensive clinical studies showed no evidence of sarcoidosis except for a few cystic lesions in the first phalanx of the right middle finger on x-ray examination. The primary tuberculin test was positive. Culture of the cerebrospinal fluid was negative as was innoculation into guinea pigs. Serological tests were negative for syphilis, histoplasmosis, trichinosis, blastomycosis and coccidioidomycosis. A muscle biopsy was not remarkable. The cerebrospinal fluid sugar was 83, 50, 57, 61 mg. per cent, the last three probably being abnormally low.

Following discharge, weakness of the extremities appeared, ataxia increased, and one year later the patient was unable to walk or stand, living a bed and chair existence. He could still feed himself, was continent and his mind remained relatively intact. The resemblance of the histological appearance in this case to some of the others just described was striking, although neither necrosis nor other evidence of damage to the arterial walls was noted. The blood pressure was always normal. Sarcoidosis has by no means been excluded.

Thus it is becoming clear that clinically there is a cerebral form of granulomatous angiitis in which the neurologic features of the illness predominate over the manifestations of involvement of other organs. Pathologically, the cerebral form is usually part of a generalized process and only in the Cabot case[83] were the lesions proved to be limited almost exclusively to the central nervous system. In the other cases with complete postmortem examination a widespread distribution of the arteritis was the rule. Possibly granulomatous angiitis has a special predilection for the vessels of the nervous system despite Rose and Spencer's estimate of the incidence at only 3 per cent.

Meyer and others[86] (1953), reporting a case which appears to fall within the same group, classed the process as sarcoidosis. In their case, a man aged fifty-one had had headache for ten days before admission and was confused for three days. On examination he was febrile, lethargic and disoriented. The cerebrospinal fluid was under a pressure of 350 mm. of water, contained 10 lymphocytes, 80 to 215 mg. per cent of protein, and

on the third examination was slightly xanthochromic. X-ray of the chest showed patchy and linear densities at the bases of both lungs. The patient's condition steadily deteriorated and he died six days after admission, about sixteen days after his illness began. Pathologic examination showed granulomata in the lungs, kidneys and lymph glands. Frequently they were perivascular and adventitial. The cerebral vessels as they lay in the subarachnoid space were involved in a similar granulomatous reaction which was chiefly perivascular but also extended to the media and several arterioles showed acute necrosis of all layers and recent thrombosis.

The authors found references in the literature to two similar cases described by Zollinger[87] (1942) and ascribed to sarcoidosis. Both cases were reported very briefly: the first was a twenty-one-year-old man who rapidly developed the picture of widespread multiple sclerosis. At necropsy there were granulomas in the brain stem and basal ganglia lying exclusively in the Virchow-Robin spaces and consisting of lymphocytes, epithelioid cells and atypical Langhans giant cells without caseation. Here and there a vessel wall was invaded but the endothelium always remained intact. The second case was that of a woman aged seventy-eight who died in three months of a progressive paralysis of the limbs and face. The pathologic picture was similar to that in the first case but the subarachnoid space also contained granulomas. In both cases the only extracranial tissues involved were lymph glands, especially the hilar nodes of the lungs.

The authors raise a very interesting point concerning etiology and one which cannot be conclusively settled so long as there is no specific or unique criterion clinically or pathologically for the diagnosis of sarcoidosis. A personal review of the published pathologic studies of sarcoidosis with involvement of the nervous system showed no other cases in which the cerebral arteries were undergoing a necrotizing change. Indeed, the only pathologic evidence of an arteritis in sarcoidosis was found in the kidney in Case 9 of Ricker and Clark[88] (1949). Regarding the clinical picture, the cases of Zollinger and Meyer and others bear little or no resemblance to any case of sarcoidosis in the literature. If their cases were in fact an acute or fulminant type of sarcoidosis, one might speculate that the cases of granulomatous arteritis running a clinical course of nine months to four years represent a more chronic form merging imperceptibly with classical sarcoidosis. In the more chronic cases of granulomatous angiitis it is essential to distinguish a granulomatous meningitic process from a primary arteritis, keeping in mind that the subarachnoid space contains so many blood vessels that any subarachnoid process must of necessity surround many of them. Also the possible effect of elevated blood pressure in producing or modifying arterial lesions must not be forgotten.

Finally to be mentioned is an unusual case reported by Rottino and Hoffman[89] (1950) in which a patient with typical Hodgkin's disease developed headache, dysarthria, mental confusion, a pill-rolling tremor, lassitude, failure of the pupils to react to light, convulsions, amnesia, incontinence, athetoid tremor and disorientation in all spheres. Pathologic examination showed a hemorrhage 4 cm. in diameter in the lateral portion of the left frontal lobe and in the immediately adjacent parietal lobe. Sections from many regions of the brain contained granulomatous lesions with a predilection for blood vessel walls. The simplest lesion was a perivascular infiltration of lymphocytes; more complex ones had epithelioid cells arranged like a tubercle and giant cells were seen in some lesions. The brain substance was not involved. There were no Sternberg-Reed cells or organisms. The authors found reports of only four other cases of encephalitis in Hodgkin's disease and none had taken a sarcoid form.

3. *Idiopathic Arteritis of the Aortic Arch and Its Branches (Takayasu's Disease).*—With an occasional exception (see below), the manifestations evoked by this condition have been the result of occlusion of the large vessels arising from the arch of the aorta and the production of ischemia distally. Although the intracranial vessels are not directly involved, neurologic signs due to cerebral ischemia are prominent. Usually girls and young women are afflicted, the age at onset varying from eleven to thirty-six years. The condition predominates in females nine to one. The clinical picture (the aortic arch syndrome) is now well known and includes absence of pulsations in the carotid and temporal arteries and the arteries of the upper extremities, diminished or absent blood pressure in the arms, sometimes hypertension in the lower half of the body, postural syncope, a tendency to hang the head forward, convulsions, dizziness, a predisposition to tussive syncope, cere-

bral claudication, hemiparesis or numbness, aphasia, intellectual deterioration, loss of vision (transient or permanent monocular blindness), optic atrophy, attenuation of the retinal arteries, a visible change in the retinal circulation with changes in posture, cataract, retinal peripapillary arteriovenous anastomoses, retinal vein aneurysms, atrophy of the iris, unusual facial pallor, atrophy of facial tissue, pigmentation of the skin of the face, 'trophic' ulceration of the face, palate or nasal septum, atrophy of gums, loosening of the teeth, loss of scalp hair, lowered mouth temperature, hypersensitivity of the carotid sinus reflex, fatigue of muscles upon chewing, intermittent claudication or weakness of the arms, enlarged collateral arterial channels over the chest at times associated with a thrill and notching of the ribs and raised sedimentation rate. The duration of the symptomatic part of the illness is usually several years and the process probably exists silently for some time before manifesting itself. The other causes of the aortic arch syndrome must always be excluded—atherosclerosis with thrombosis, syphilis, tuberculosis, and healed aortic dissection.

Although the first description of the ocular signs was made fifty years ago, pathologic studies of the disease are still relatively rare. Clinical case reports are appearing with increasing frequency (see Ask-Upmark[90] and Ask-Upmark and Fajers[91]) but the following summary will be limited for the most part to cases which have come to necropsy. In Harbitz (and Raeder's) case[92] (1926), a woman aged thirty-seven, had complained of attacks of flickering vision and recurrent bouts of paresis of the limbs; on examination mental changes, retinal vein aneurysms, atrophy of the face and iris, interruption and intermittency of the blood flow in the retinal arteries and cataract were found. There was no radial pulse on either side and the patient died after suffering successive hemiplegias. At postmortem examination the right subclavian, right common carotid, right vertebral and left common carotid arteries were occluded totally, the left vertebral partially. There was a left cerebral softening. Microscopically, the wall of the left common carotid artery showed fibrous thickening with a heavy inflammatory infiltration along the vasa vasorum containing lymphocytes but no giant cells. The carotid lumen was occluded by vascular fibrous tissue. The right common carotid artery was similarly but less affected while the right internal carotid artery showed no infiltration. The aorta showed an extensive infiltration of lymphocytes and plasma cells but no giant cells.

Marinesco and Kreindler's[25] (1936) patient ran an eight-year course characterized by transitory amblyopia as well as steadily failing vision, giddiness, headache, seizures (particularly on exertion), left hemiparesis, cerebral claudication, and atrophy and pigmentation of the face. Death followed cachexia associated with loss of all her teeth. Postmortem studies showed that the four large vessels arising from the arch of the aorta were occluded by an organized thrombus. No inflammation was seen and at death a fibrocaseous peritonitis was described.

The patient described by Sato[93] (1938) showed the classical picture of Takayasu's disease with arteriovenous anastomoses in the retina and absence of pulsation in all vessels arising from the arch of the aorta. Biopsy of the axillary and carotid vessels revealed occlusion without signs of inflammation. Because the Wassermann reaction of the blood had been strongly positive before the author saw the patient (although negative at the time of his examination) he concluded that syphilitic aortitis was the cause of the syndrome.

Frøvig's[94] (1946) patient, a young woman aged twenty-one, first noted slight periodic curious sensations in her right arm which she could not describe very clearly. They were accompanied by headache, vomiting and obscurations of vision. Later the attacks included weakness of the right leg and difficulty in finding the right word. Six months from the onset a right hemiparesis occurred and a few months later the left side became affected. Transient blindness on walking was noted and cataracts formed bilaterally. No pulsations were felt in the arteries of the arms and neck. Biopsy of a carotid artery showed occlusion of the lumen by proliferated connective tissue. In this specimen there was little or no inflammation but pathologic examination[95] (1951) upon the patient's death (several years after the onset of her illness) showed a giant-cell arteritis of the aorta and the large branches arising from the arch. The cervical portion of the vertebral artery showed moderate intimal proliferation and scattered perivascular lymphocytes. The descending aorta was massively involved. The intracranial vessels were almost free from end-arteritic changes although the cerebrospinal fluid contained up to 227 monocytes per cu. mm. A most extensive collateral system of anatstomotic channels was found

in the neck and the upper ribs were notched. The temporal arteries were not involved clinically. The authors considered the various possible causes and suggested that the arteritis was an allergic-hypererergic response.

Maspetiol and Taptas[96] (1948) recorded the case of a young woman aged twenty-three who presented unexplained ulceration of the nasal mucosa, unusual facial pallor and a left hemiparesis which had developed during a half hour episode of unconsciousness. While under observation, the pulse vanished from time to time from the upper extremities and after four months from the temporal arteries, although the carotid pulsations were still present. Facial diplegia and a right Babinski sign appeared and the patient died five months after admission to the hospital. At the age of eighteen the patient had been anemic, had a whitlow and pain in the upper extremities. At autopsy, the aortic arch was embedded in a mass of firm tissue which had resulted in occlusion of the right common carotid artery and narrowing of the lumen of the other large vessels arising from the arch. Microscopic examination of the right carotid artery showed medial and adventitial thickening with infiltrations of round cells and occasional giant cells, and occlusion of the lumen by a recanalized thrombus. The aortic involvement was almost wholly periarterial. The blood Wassermann test was negative.

Shimizu and Sano[32] (1951), in a review of Takayasu's disease as experienced in Japan (some thirty-three cases have been reported in Japan compared with approximately forty from elsewhere in the world), described the pathologic picture as a panarteritis with an infiltration of lymphocytes and plasma cells, and in some cases Langhans giant cells. They pointed out that the occlusive process in the carotid system may start at the bifurcation of the common carotid artery and extend proximally, rather than beginning in or adjacent to the aortic arch. Likewise, occlusion of the subclavian artery may begin distal to the origin of the vertebral artery. Only a few of the Japanese cases have been studied pathologically.

Ross and McKusick[97] (1953) in their extensive study summarize all the recorded cases of the aortic arch syndrome (or variants thereof). The patient of Ask-Upmark and Fajers[91] (1955) died at the age of forty. At the age of twenty-six corneal opacities were found and at twenty-seven, pains occurred in the arms on subjecting them to effort and the blood pressure could not be recorded in the arms. At age thirty-four cardiac disturbances appeared consisting of dyspnea and tachycardia. The blood pressure in the legs was 240/170. The sedimentation rate was 55 mm. in one hour. Pulsation in the carotid arteries was reduced. At the age of thirty-four, transitory right-sided hemiparesis occurred and the right carotid artery was explored, showing a trickle of blood. The last six years of her life were marked by effort-induced pains in her arms, reduced acuity of vision, attacks of syncope on standing up, and increasing cardiac failure. Finally the patient died in uremia. An ovarian dermoid cyst surgically-removed at the age of thirty-four showed cellular intimal thickenings of the arteries and a small artery removed from the foot at age thirty-five showed pronounced subacute inflammation of all layers of the wall. At autopsy the appearance of the brain was normal except for bilateral microgyria in both occipital lobes and in two 2.5 cm. symmetrical regions of the frontal lobes. The intracranial portions of the large cerebral arteries were normal. The innominate artery was filled with a mixture of organized laminated and fresh thrombotic material extending into the right subclavian artery which was completely obliterated. The right vertebral artery was obliterated for 1 cm. at its origin. The right common carotid artery was filled with thrombus in its lower portion but the lumen became normal some centimeters below the bifurcation. The right internal and external carotid arteries were normal. The left common carotid artery was occluded by a fibrous thrombosis extending some centimeters upwards from its origin. The left subclavian artery was likewise completely obliterated approximately to the level of the origin of the vertebral artery. Microscopically, scanty collections of round cells were found in the adventitia of the innominate artery, common carotids and subclavians. The authors assumed that the arteritis had originally involved all layers of the arteries. Organized thrombus lying at the origins of the renal arteries and almost completely blocking their lumens, accounted for the terminal renal failure.

Recently, Barker and Edwards[98] (1955) described the case of a woman aged sixty-four with substernal pain and increasing cardiac failure of one year's duration. No pulses were felt in the upper extremities except in the left subclavian artery above the clavicle. Postmortem examination

showed myocardial infarction with an overlying mural thrombus. The left subclavian and right axillary arteries were occluded by organizing thrombus. The walls of the left common carotid and the innominate arteries were thickened but the lumens were patent. Microscopically, the entire thoracic aorta, the branches of the aortic arch and the axillary arteries showed an extensive chronic inflammatory reaction. The coronary ostia were narrowed by the inflammatory process in the adjacent aorta. The authors rejected the possibility that embolism had been responsible for the vascular occlusions and rightly concluded that thrombosis *in situ* had occurred In this case there was a modified aortic arch syndrome but no cerebral symptoms had occurred. The temporal arteries were not involved clinically. Insofar as the case resembles Takayasu's disease, it is of special interest from three aspects: (1) the age of the patient, (2) no giant cells were found in the inflammatory reaction, and (3) the coronary ostia were involved.

Beneke[99] (1925) described a case which, although far from typical, bears some relationship to Takayasu's disease. It concerned a woman of forty-one who at the age of thirty-six was seriously ill with epidemic influenza (1918), following which she remained an invalid. At thirty-nine the blood pressure was 180/120, the patient was edematous and a loud aortic systolic murmur was heard. At thirty-nine a left hemiplegia came on suddenly and the cardiac murmur was louder over the great vessels of the neck and abdomen than over the base of the heart. Death resulted from bronchopneumonia. Autopsy showed extensive thickening, chiefly adventitial, of the walls of the thoracic aorta, of the large arteries arising from the arch and of the abdominal aorta whose lumen was greatly narrowed. Microscopically the media of the involved vessels was destroyed and the adventitia greatly increased; a few regions showed a scanty infiltration of inflammatory round cells and rarely giant cells were seen. The author concluded that he was witnessing the chronic stage of a process whose acute phase had taken place many months or years before, possibly during the influenzal illness. The hemiplegia was caused by a hemorrhage into the right putamen and the carotid arteries were not significantly obstructed.

Joób[100] (1947) described the case of a thirty-two-year-old woman with increasing dyspnea for many years. There were signs of mitral valve disease in addition to the classical picture of cardiac failure. The blood pressure in the right arm was 150/100; left arm 225/120. The sedimentation rate was 134 mm. An autopsy showed only severe aortic atherosclerosis without evidence of inflammation. The right axillary artery was almost occluded. This case, although included in some references to the subject of arteritis, does not belong in that category.

With the possible exception of Barker and Edward's case, the fully developed clinical picture of idiopathic arteritis of the aortic arch and its branches has been rather uniform. It has already been mentioned that in no case was temporal arteritis evident, and on the other hand temporal arteritis has not been reported as a cause of the aortic arch syndrome. The data presented in this brief review provide sufficient justification for keeping the two diseases separate at the present time. In the recognition of Takayasu's disease, it is important not to overlook cases with merely a partial syndrome in which only one, two or three of the main brachiocephalic trunks are obstructed.

Summary

1. Two cases of temporal arteritis with extraocular motor palsies have been described. In addition, in Case 1, the clinical picture included diabetes insipidus, dysphagia, trismus and periorbital swelling.

2. The literature pertaining to extraocular palsy in temporal arteritis has been reviewed.

3. Attention is drawn to the occurrence of transient diabetes insipidus in Case 1. The possibility that involvement of the region of the optic chiasm accounts for the pattern of blindness in some cases of temporal arteritis is raised.

4. The occasion has been taken to summarize the present status of temporal arteritis in relation to the other arteritides.

5. The neurologic manifestations of temporal arteritis, periarteritis nodosa, granulomatous angiitis and idiopathic arteritis of the aortic arch and its branches. (Takayasu's disease, aortitis of the young female) have been reviewed and compared.

The Relationship Between the General Practitioner and the Specialist

W. B. HILDEBRAND, M.D.
Menasha, Wisconsin

JOHN S. DE TAR, M.D.
Milan, Michigan

Here is a concise presentation of the important role of both the generalist and the specialist in our society.

THE relationship of the Generalist and the Specialist and the place of each in the world of medicine during the next generation constitutes one of the most widely discussed subjects and one of the most pressing problems in medical circles today.

The question is often raised as to whether in today's medical world of specialization, with nineteen recognized specialties, five sub-specialties and twenty-seven subdivisions of specialties, there is actually a place or even a need for general practitioners. And if there is a need, what kind of a doctor should he be? What should be his training? Is a one year rotating internship sufficient to enable him to discharge his responsibilities? Should the specialties share the responsibility with the medical schools for the continuous education of the family physician? Or, is the internist destined to become the family doctor with complete elimination of the generalist?

The answers to these questions are very important—important to medical educators who are currently making drastic alterations in the pedagogy of preclinical and clinical training and important to the American people whose attitude will in the long run determine whether the family physician is to survive or perish. And in this day of Kaiser-Permanente plans, health insurance plans, community health association plans, United Mine Worker funds, salaried physicians, the practice of medicine by Blue Cross, and the elevation of the hospital to the point where the board of trustees may dominate the practice of medicine, the study of the future of the general practice of medicine and its relationship to specialization becomes even more engaging.

The American people are not ignorant of the advance of medical knowledge. They know that with the tremendous development of specialized techniques in anesthesiology, in medicine and in surgery, the complete consultation facilities of a departmental hospital offer the very zenith of diagnostic and therapeutic skill. And yet, they sense that with today's super-specialization something has been lost in the triumph of scientific medicine.

Something has been lost in this rapid march of science in the treatment of human beings. That something is the human individual himself—the human being with a soul.

The treatment of the sufferer as just a mass of diseased protoplasm with a hospital number attached to him goes far afield from the tender solicitude of the old family doctor who breathed confidence and courage into his patient, although he sat at the bedside with few specific agents at his command.

Presented by Dr. Hildebrand at the annual meeting of the Minnesota State Medical Association, Duluth, May 25, 1959.

Doctors Hildebrand and DeTar are both past presidents of the American Academy of General Practice.

While the modern trend of specialization has elevated the science of medicine although neglecting its art, one cannot blame today's medicine for a fault which is of ancient origin. Centuries ago Plato complained, "For this is the great error of our day in the treatment of the human body, that physicians separate the body from the soul." Voltaire was just as critical, but a bit more spicy: "A physician is one who pours drugs of which he knows little into a body of which he knows less."

These are all simply different modes of expression of the same thought: that the patient, the sick person, whether in Plato's time, in Voltaire's time, or in our time, values the treatment of his soul equally with the treatment of his body.

Is there a gross incompatibility between the science and the art of medicine? We hold that there is not. We do not accept the old adage "the more the art the less the science."

What is "the art?" There are many definitions. We like this one: "The art of medicine is the skill with which the physician applies his technical knowledge."

Art must complement and supplement science. Neither can exclude the other and still constitute adequate therapy. The highest quotient of art is compatible with the utmost degree of science.

These statements revolve around the basic problems of generalist-specialist relationships.

It is quite apparent that American medicine is just as concerned with the soul of the patient as were Plato and Voltaire. The medical school, the American Medical Association, the American Academy of General Practice and all of the specialties are concerned.

This concern and the actions resulting therefrom are of great importance to medicine as a whole, not just to general practice or to specialization. They are of importance to young physicians seeking to find their proper place in the medical economy of tomorrow.

Medical students are tremendously interested in hearing about general practice. They are concerned with the quality of practice, with hospital privileges, with board certification. They wonder if they should become certified in internal medicine in order to do high quality general practice, and if so, how they will receive adequate training also in pediatrics, obstetrics and the care of traumatic cases.

However, despite the obvious need for a greater supply of family physicians, and despite the just as obviously expressed desire of the American people for an increase in the supply of family physicians who will assume this total continuing responsibility for the health of the individual and his family, there is incontrovertible evidence to prove that our present system of medical education and our present system of hospital organization are contributing to the demise of the general practice rather than to its survival.

Look at the figures: Only 30 per cent of the class of 1930 were found in general practice five years later. This figure went down to 26 per cent of the class of 1945 and 18 per cent of the class of 1950. Projection of this curve to 1980 would approach the zero mark. Fortunately there are signs that the pendulum may be swinging upward again, but not rapidly enough to compensate for replacement, let alone a population increase of over three million a year.

Ninety-four per cent of all residents are now engaged in specialty training and only six per cent are engaged in training for general practice, despite a surplus of general surgeons and a shortage of general physicians.

There are some very definite reasons why medical students and interns who start with high idealism of service to mankind through the medium of general practice finally finish their training in a specialty. These reasons fit into three categories: First, medical school training by specialists having no contact with and no understanding of general practice. Second, graduate training during internship and residency providing unlimited high quality training programs for the specialties and the extremely limited residency opportunities in general practice. Third, the fear of interns, that if they do take general practice residency, their hospital privileges will be no greater than if they had not spent the extra year or two years for proper preparation.

One student describes his training for general practice like this: "Here there is no subject matter in general practice—no family to visit to follow through our medical teachings. Marked dogmatism in each department is present with apparently little attempt made to look at the patient as a whole. If it's an itch—to the allergy clinic. If it's an itch with a rash—to the dermatology clinic. If she's bleeding, GYN gets her. If she's not bleeding, send her to the endocrine clinic. If it's a joint ache, then the orthopods and arthritic clinic

will have a fight over it, and one by one it goes down the line. It's all topped off by the university frowning on rotating internships."

There is little wonder that his school and many others are producing a plethora of specialists experiencing difficulty in locating where they are needed, and a shortage of generalists who are needed but not being produced.

Fortunately, this picture is changing a little.

But first, how about the fear, and the legitimate fear, of the intern that he will not be allowed to practice good medicine in the hospital of his choice as a generalist; the fear that he will not secure a staff appointment, and if he does that he will have no opportunity to demonstrate his professional competence and to secure privileges in proportion to his capacity?

The Wisconsin Surgical Society recently drafted into its by-laws a directive which prohibits its members from participating in any type of preceptorship training program and from assisting a generalist at the operating table.

The Griffen Hospital at Derby, Connecticut, has removed all extension of surgical privileges except for physicians who are board-certified. There is no provision for recognition of demonstrated ability.

A hospital in Newark, New Jersey, will not let a generalist do a simple episiotomy or rupture membranes, not even with the permission of the chief of the section of obstetrics or the resident in obstetrics.

One generalist in Richmond, Virginia, reports that the generalist must turn over his emergencies to a specialist in order to get a bed for his patient.

One generalist in Baltimore, Maryland says that he can admit patients below the age of twelve or above the age of twelve, but not both. In other words, he may practice pediatrics or medicine, but not both.

One of the interns in Pittsburgh applied for staff privileges at the Mercy Hospital where he was finishing his internship. He was told that the staff was sorry, that he had been good enough to intern there but that staff privileges were restricted to specialists and he would do better to apply elsewhere. He applied at the Southside Hospital. There he was told the staff was sorry but he would not qualify because he had not interned there. Do you think such examples as these are shocking? We do. We think they demonstrate a cleavage between specialists and generalists which threatens the very structure of private practice as we know it today. The same cleavage preceded the advent of socialized medicine in Britain. It involves not only professional jealousies, professional selfishness, the prelude to the end of general practice, the threat of governmental control, but it also involves the whole economics of medical care.

The cost of medical care is intimately related to the question of whether the hospitalized patient is shunted from specialist to specialist without supervision of the family physician who knows him best, or whether the personal physician is allowed to supervise his care, utilizing specialty consultation but exercising the guiding hand of control over his financial and medical interests and providing continuity of medical attention. The proper supervision of the patient is directly related to the total cost of his illness and to the direct corollary thereof, government control of medical care.

There must be some middle ground between unlimited, uncontrolled, unchecked low-quality hospital practice and the absurdities of exclusion and limitation. From every point of view, that of sound medicine and that of sound economics, the generalist should be integrated into the modern hospital organization.

Neither the generalist nor the specialist is equipped to render complete medical service; each must be complemented by the other.

The diagnosis of the nature of the generalist-specialist problem is relatively easy. Put in a nutshell, the etiology of the problem is fivefold:

1. The rise of the specialties in keeping with the rapid advance of scientific knowledge.

2. The overproduction of specialists and the underproduction of generalists.

3. The development of the hospital as a community health center, with expensive diagnostic and therapeutic facilities that no one practitioner can finance, a trend aided and abetted in no small degree by the rapid rise of voluntary sickness insurance—our own Blue Shield and Blue Cross.

4. The voluntary self-regulation of the profession and the hospitals in the interest of elevating standards.

5. The insistence by some specialists that board certification be accepted as the standard of competency, countered by the insistence by generalists that demonstrated professional capacity and not

board certification be so accepted. No generalist can show certification in medicine, surgery, obstetrics and pediatrics.

To these five causes may be added the foibles and shortcomings of the human personality with the admission that not all doctors are immune to selfishness and professional jealousies.

The therapy is more difficult. It involves many factors, six of which might be mentioned.

1. Specialists must recognize that the development of medical technology does, in truth, limit the field of every physician, generalist and specialist and that no one physician can cover the field. Further, the generalist must define with greater accuracy the field of general practice.

2. Specialists must recognize that the generalist must be accorded a place in the community hospital. He must first have that membership.

3. Specialists must agree to the allocation of hospital staff privileges in accordance with demonstrated professional capacity and must be willing to cooperate in a teaching program which will enable the generalist to engage in a continuous educational process, thus fulfilling his obligation to both his profession and to society.

4. Medical education must undergo radical alteration to the end that emphasis once again will be placed on the patient as a person rather than on his regional pathology. In other words, the patient must be desegmentalized. Medical educators must so alter their program that the product will be a well-trained, undifferentiated physician prepared for either a specialty or general practice. And this is not an easy task.

5. The outmoded, antiquated, inadequate one-year rotating internship must be abolished and in its place must be established a two year properly organized residency or prolonged internship, as the case may be, for general practice which will enable the young generalist to discharge his professional responsibilities in keeping with today's high standards of medical care.

6. Board certification in general practice must be established not only to afford the hospital staff a means of appraisal of the young generalist applicant, but also to provide a goal of attainment for the general practice resident, without which general practice residencies will continue to go begging.

This may sound to you like a lot of medicine for the cure of disease, but I want to assure you that work is in progress in every single one of these fields and in some it is progressing very rapidly.

In 1953, the AMA House of Delegates directed that a new committee, the Committee on Medical Practices, should start work in an attempt to determine the underlying causes of these unfortunate relationships between specialists and generalists and to recommend a solution. That committee reported first in 1954 with definite recommendations on which the House of Delegates acted:

"It was never intended that staff appointments of hospitals generally, or even in hospitals approved for residencies, should be limited to board-certified physicians as is now the policy of some hospitals. Such policies, if practiced extensively, are detrimental to the health of the American people and therefore to American medicine. Hospital staff appointments should depend on the qualifications of physicians to render proper care to hospitalized patients as judged by the professional staff of the hospital and not on certification or specialty society membership."

The House proceeded to direct that the Committee on Medical Practices be a continuing committee to report every six months, which has been done since December, 1955. Sub-committees have been appointed which are hard at work on many facets of the problem. Medical education circles have reacted to the potentials engendered by the formation of this committee. Many medical schools have set up departments of general practice, and the Congress on Medical Education devoted an entire meeting evaluating education for general practice.

As a result of the long work of this Committee, the AMA House of Delegates will soon hear the recommendations of the special sub-committee on preparation for general practice on a new two year program proposed for medical school graduates planning to become family physicians. This is, in a sense, an expansion of the one year rotating internship which most generalists now take and would replace the present internship. Family practice was chosen as the name for this field since the emphasis is on the medical care of the family regardless of age. The sub-committee predicted that there would be an increased need for the family physician.

A minimum of eighteen months experience in the diagnostic, therapeutic, psychiatric, preventive and rehabilitative aspects of medicine and pedia-

trics should, in a very broad sense, be part of the two year program.

A physician could then elect to spend the remaining six months of additional study in any part of the program that he desired. However, a physician who plans to practice obstetrics should spend at least four months of the elective period in obstetrical training. This entire plan will be reported in detail to the AMA House of Delegates meeting in Atlantic City.

The American Academy of General Practice has taken the lead in the fight for the development and production of better trained generalists, with the realization that the generalist must elevate his standards if he is to survive, that he must engage in continuous post-graduate studies to elevate these standards, and that he must fight for the right to practice in the hospital of his choice in accordance with his professional talents.

The Academy of General Practice believes that the education of its members should be a continuous process. It believes that education on the hospital staff level should be a continuous process and that no applicant, generalist or specialist, should be accorded full privileges on any hospital staff until the staff has had an opportunity to observe him in the discharge of his professional duties. It believes, with the cooperation and assistance of the internist, the pediatrician, the obstetrician and the surgeon, that a great contribution can be made to the quality of medical care by a program of continuous in-hospital training in each department in which a generalist works.

The Academy believes that such in-hospital training and sponsorship will provide, not only education, but incentive for young generalists and it will swell the ranks of family physicians.

It is an interesting observation that all of the resolutions on the improvement of general practice and the right of the generalist to hospital staff privileges in accordance with his ability which were passed by unanimous vote of the House of Delegates of the American Medical Association, were so passed by a body consisting of over 75 per cent specialists voting, not in selfish defense of their own specialties but rather in defense of the institution of general practice which they considered an integral and important segment of American medicine.

It cannot be said that specialists as a class are blind to the dangers inherent in the threatened extinction of general practice.

It cannot be said that the bigoted and myopic attitudes of some specialists represent the majority any more than can it be said that those generalists who demand surgical privileges exceeding their professional competence represent the majority.

It cannot be said that generalists as a class are satisfied to render second-rate medical care or are blind to the necessity of maintaining pace with the advance of medical knowledge and technology. It cannot be said that today's medical educators as a class are satisfied with their techniques or their results.

The expressed attitudes of the American Medical Association, the Specialist societies, the American Academy of General Practice, and the Association of American Medical Colleges all attest to the truth of these statements, exceptions to the contrary not withstanding. The locus of greatest need today is on the hospital staff level. It is our personal impression that problems on this level in most areas through the country show promise of solution.

The signs of progress are most encouraging. After all, there are few questions of such gigantic complexity that they cannot be analyzed and solved by reasonable intelligent people sitting together around the conference table.

When the attitudes and policies of the national medical organizations have found their way into local staff organizations in hospitals, these problems which have loomed so large in the recent past will evaporate, a process which will be beneficial not only to the generalist and the specialist and to all of medicine, but also to the too often forgotten man—the man who pays the bills—the patient.

The Norse god Thor was once taunted by the giant Utgard-Loki into attempting various tests of strength and prowess. Among them he was challenged to lift a cat. To his humiliation, Thor found that he could not budge the animal. It turned out that this was no ordinary cat. It was the exposed portion of the fabulous Midgard serpent whose body encircled the earth. Trying to lift it, Thor had been straining to lift the entire world. I would hope that every resident in specialties and every specialist could be made to understand that his specialty is Loki's cat, and that what he sees of it above the surface may appear small and easily manageable but that in reality it is of necessity bound to the universe.

THE LAW-MEDICINE CENTER

An Experience in Working Together

The philosophy of the Law-Medicine Center in Cleveland is based on the belief that society must solve certain medico-legal problems of man through unity and not diversity, through one center and not two schools, through mutual cooperation and not divisive controversy. Medicine and law when they have met in the administration of justice have too often generated much conflict and confusion. Not only have law and medicine suffered but also justice.

The specific purpose of the Center is to improve the administration of justice—both civil and criminal—through better use of medicine as a source of truth for the law.

In 1953, to achieve this purpose, Western Reserve University and the Cuyahoga County Coroner's Office cooperated to present an instructional program in law-medicine problems. That year the Coroner's Office opened its new $800,000 laboratories on the University campus adjacent to the School of Law, School of Medicine and Institute of Pathology. This public health office of local government has major medico-legal problems in its daily activity. Dr. Samuel R. Gerber, Coroner since 1936, University officials, and public-spirited citizens labored for several years prior to educate the voters of the County on the wisdom of voting for the necessary public bond issue to build a new scientific coroner's office in the University environment. By an overwhelming vote the concept and the building were approved.

The cooperation between the governmental office supported by the taxpayers of the county and the privately endowed, voluntarily supported University has grown broader and deeper since 1953. The spearhead for this cooperation is the Law-Medicine Center officially created by the University trustees in 1954.

Administration of the Center rests in the director, a full-time member of the School of Law faculty, the Cuyahoga County Coroner, Dr. Gerber, and the Director of the Institute of Pathology, Dr. Alan R. Moritz, who also serves as Professor of Pathology in the School of Medicine and is an internationally recognized leader in forensic medicine.

In the University structure, the Center represents not a school but a service institution. For University administration the Center is placed under the Dean of the School of Law. The vigorous support of Dean Emeritus Fletcher Reed Andrews and the present Dean, Dr. Edgar I. King, has been a potent factor for success.

The law-medicine program completing an operation of seven years in February, 1960, has conducted fifty-two separate courses or schools for instruction. In civil justice, sixteen courses or seminars have been given; in criminal justice, thirty-six courses or schools. The student registration for civil justice instruction has totalled nearly 1,200 while criminal justice has attracted over 1,300. These students represent doctors and lawyers, law students and medical students, law enforcement officials (police, prosecutors, probation and parole officers, coroners and medical examiners), insurance claimsmen, industrial relations personnel, labor union officials, social workers, and others. Nearly 300 individuals have served as instructors both from the University faculty and the community of Greater Cleveland, the state of Ohio and beyond.

Current budget of the Center is $40,000 annually. The bulk of the expense is measured by faculty honoraria. In 1954 a $20,000 grant from the Cleveland Foundation, America's pioneer community trust, enabled the program to begin. Since then several interested corporations and individuals have given a total of $7,500 but in the past year only $1,000 of the income came from gifts. The remaining $39,000 represented tuition and service fees, primarily the former.

The Center has published several books and monographs, has conducted research, has provided surveys for law enforcement agencies and has tested law enforcement personnel. Details of these functions—instruction, publication, research, sur-

Mr. Schroeder is Professor of Law; Director, The Law-Medicine Center, Western Reserve University, Cleveland 6, Ohio.

vey, testing—will be described in articles to follow. Some challenging aspects of future law-medicine problems will also be presented.

The central theme of philosophy, purpose and function at the Center—*to use medicine in law to achieve justice*—is vitally affected by man's current law-medicine knowledge and skills being in a state of volatile change. Law and medicine when cooperating in the administration of justice must be prepared to recognize this condition of swift change in modern man's intellect and above all to adapt to this condition to resolve human problems in the medico-legal area. A free, democratic society laboring cooperatively through public offices and private enterprises is our best hope in today's challenging world. The Law-Medicine Center is a unique cooperative activity of such labors by government and university to solve a common problem. By-products of the activity are the dignifying of the professions of law and medicine but, more important, better service to the client-patient—an individual human being with complex medico-legal problems.

OLIVER SCHROEDER, JR.

DIGITALIS TREATMENT OF HEART DISEASE

There have been a number of recent discussions concerning the use of Digitalis. It is most interesting to all who have been concerned with the use of Digitalis in the treatment of heart disease, that despite all of the advances by the pharmaceutical houses and the pharmaceutical chemists, very little has been added to the basic understanding of Digitalis. The multiplicity of the products on the market are totally confusing to most physicians and it is suggested now that the physician should select one whole leaf product, an oral glycoside, and an intravenous product as part of his armamentarium. It is not necessary to know all of the Digitalis preparations on the market. It is only necessary to know the characteristics of the preparation to be used. Nothing is gained by jumping from one product to another. For those patients who do not require digitalization, the whole leaf product is still the best. In individuals who require rapid digitalization and who can take the drug orally, it is suggested that an oral glycoside should be used. For those individuals in whom the emergency is great and no other method seems available, intravenous use of Digitalis is indicated.

The indication for the use of Digitalis, except for certain arrhythmias, is heart failure.

In heart failure Digitalis should be given until there has been complete digitalization. The amount of Digitalis that produces digitalization varies from individual to individual. The drug, however, should be given until the symptoms of digitalization appear. Once the patient is digitalized, he should be kept on maintenance doses of Digitalis. The knowledge that has been added to our better understanding of Digitalis has altered in no way the original directions given by Withering, the discoverer of Digitalis. When digitalization is indicated, it must be remembered that effective digitalization results from individualization.

SYPHILIS IN MINNESOTA

The report of syphilis as a problem in Minnesota is most gratifying. The issue of *Minnesota's Health,* Volume 13, Number 2, gives a succinct account of the solution of the syphilis problem in this state. Unfortunately, the title of this article reads "Minnesota Eliminates Syphilis as a Serious Public Health Problem." Dr. H. G. Irvine would be the last to believe that syphilis is no longer a serious public health problem. His wisdom, his clinical knowledge and his superb understanding of the venereal disease problem brought about our envied position in venereal disease control. It must be emphasized that we have not eradicated syphilis; we have controlled it. The success of Dr. Irvine's program will continue only as long as all lay and professional groups continue their moral and financial support to his philosophy of "syphilis control."

EPIDEMIOLOGY OF LUNG CANCER

In the past twenty-five years, the death rate from lung cancer among male residents in the United States has risen from four to twenty-four deaths per 100,000. Lung cancer is responsible for about 10 per cent of all cancer deaths and is the most frequent cause of cancer death in the male patient. The increase in deaths due to lung cancer is primarily limited to males and to the epidermoid and undifferentiated types of carcinoma. Presently, to every female death there are between four and five males who succumb—and this ratio seems to be widening.

A great deal of speculation exists on how much of the above increase is real. The above statistics are obtained from death certificates and necropsy studies. It is well known that data from death certificates can be erroneous. Our increasing longevity, better diagnostic methods and accuracy, and increased awareness of this disease form the basis for the belief that much of the increase in incidency is relative. When the above three factors are taken into consideration, it still appears that there has been a real increase in lung cancer during the last twenty-five years.

Our present concept of the etiology and pathogenesis of lung cancer postulates that this disease results from chronic exposure of the bronchial epithelium to external irritants or carcinogenic materials. Carcinogenic materials paralyze the normal sweeping action of the ciliated bronchial epithelial cells. The irritation produces increased mucous secretion, distention of the goblet cells, and a crowding out of the ciliated cells. This gives the carcinogen access to underlying basal epithelial cells and over a period of time there is progression from basal cell hyperplasia to squamous metaplasia, cancer *in situ,* and finally bronchiogenic carcinoma.

Evidence is available that prolonged contact with chromates, asbestos, arsenic, and nickel are associated with an increased incidence in lung cancer. During the last decade, and particularly in recent years, excessive cigarette smoking has taken the spotlight as the major cause of lung cancer. The advocates of the cigarette smoking theory base their argument on approximately thirty retrospective and prospective studies which have been conducted in this country and in England. All of these studies show a statistical association between excessive cigarette smoking and the incidence of lung cancer. Many of the conclusions of these studies have been questioned for the following reasons: (1) the problem of inaccuracies in data obtained from death certificates, (2) the problem of obtaining accurate retrospective smoking histories, (3) and bias in selection of participants in the prospective studies.

The prospective studies not only show a statistical association between smoking and lung cancer but also with almost every disease investigated. This immediately brings up the question, "Is it possible that cigarette smoking can be responsible for so many dissimilar diseases?" The proponents of the cigarette theory believe this is possible, while the opponents sight this as further evidence for questioning the accuracy of these statistical studies.

Probably the most important contribution of these statistical studies on smoking has been to stimulate basic research on the possible etiologies of lung cancer. Studies on the bronchial epithelium in smokers and non-smokers have shown that the degree of change in the epithelium from loss of ciliary action to carcinoma *in situ* is roughly proportional to the number of cigarettes consumed. It has also been shown that certain aromatic hydrocarbons in tobaccos are carcinogenic for certain animals.

The studies on the bronchial epithelium were done on autopsy specimens taken from persons who died from lung cancer and other causes. The majority of these patients were in the fifty to sixty-five year age groups. It would be well to try to correlate smoking histories and epithelial changes in persons in the third, fourth, and fifth decades of life to learn how long it takes to bring about the mentioned degenerative changes.

It appears that a great deal more research on the physiology of lung cancer plus animal experimentation and identification of carcinogenic agents is needed before we can make the statement that cigarette smoking is the major cause of lung cancer. Certainly, heredity, socio-economic level, occupational contacts, air pollutants, and other factors need further consideration as etiological agents. Maybe cigarette smoking is not the conclusion to the book on lung cancer, but only one of its chapters.

WAYNE MATHY, M.D.

SPEED AND TRAFFIC ACCIDENTS

Excessive speed was by far the biggest single cause of traffic accidents that caused more than 2,825,000 injuries and 36,700 deaths on U. S. highways during 1958, according to a recent insurance company report.

It was estimated that speed killed and injured nearly 1,000,000 persons in the United States last year, more than 40 per cent of the total.

Cars that did not have the right of way were involved in 25.2 per cent of the accidents causing a total of 608,400 injuries during the year. Reckless driving was blamed for 10.4 per cent of the injuries; cutting in for 4.0 per cent and improper signaling for 3.6 per cent.

President's Letter

SINGING THE "BLUES"

In unions there is strength, and, not to be discounted, is the possibility that organized labor at its convenience will use its power to provide medical care for its members. One wonders whether or not that trend has already begun.

In New York City, for instance, the major labor unions are now seriously considering establishment of their own health insurance program and chain of hospitals "to bring medicine closer to the people." A study is being made by a special council, prompted by bitterness over the recent New York Hospital strikes and dissatisfaction with Blue Cross and Blue Shield coverage.

The union claims that "we have sweatshop health standards in our hospitals. They underpay their staffs and under serve their patients. They make no accounting to the public. Yet, we are confronted with skyrocketing costs that must be paid out of our welfare funds." They claim that labor representatives are outnumbered five to one on the Blue Cross Board of Directors. Represented on the study committee are twenty-six of New York major labor organizations, whose combined pension and welfare funds total $750 million. It was pointed out, however, that the funds are under joint labor-management administration and could not be used for hospital construction without approval by employers.

There will be a great challenge confronting Blue Cross and Blue Shield if jointly administered pension and welfare funds are used to finance hospital construction and operation and to maintain health insurance programs. "We intend," the committee said, "to determine how far short present facilities are of meeting the city's needs in terms of quality, quantity and cost."

New York Blue Cross has been criticized "for failing to heed the voice of labor." It has been pointed out that the recent increase in Blue Cross rates, in the New York area—averaging 26 per cent—meant a 33 per cent rise in rates for the type of coverage purchased by most unions and this coming on the heels of last year's 22 per cent increase. The Central Labor Council represents 600 New York local unions with a combined membership of 1,000,000—these members, and their families, comprising the backbone of New York Blue Cross and Blue Shield enrollment.

In meeting the challenge, what can Blue Cross and/or Blue Shield do? John R. Mannix, Executive Vice President of Blue Cross of Northeast Ohio, has recently stated that Blue Cross "desperately needs a shot in the arm to give it a nation-wide growth spurt" and that Blue Cross "is suffering from hardening of the arteries and has lost the pioneering spirit that sparked its phenomenal growth in the 1930's."

Mannix feels that the eighty-odd plans operating across the United States are not up to dealing, individually, with employes, and labor unions, which want nationwide coverage. Therefore, he suggests that the American Hospital Association in co-operation with the American Medical and Dental Associations, if they agree, get a federal charter for an American Blue Cross as a voluntary, nationwide organization.

The United States, noted Mannix, is the only major nation with no government-controlled health plan, but action must be taken today to strengthen the voluntary medical system of which voluntary hospitals are a key component—or else.

Sincerely yours,

Benjamin B. Foulston M.D.

DELEGATES HEAR GHAA HEALTH CARE VIEWS AND AIMS

Paul R. Hawley, M.D., Director of the American College of Surgeons, in a banquet address given in conjunction with the 1959 Institute of Group Health Associations in New York City, told delegates "there is one thing worse than no medical care; and this is poor medical care." He pointed out that "most medical care insurance plans increase quantity of care with no regard for quality, and actually encourage bad care."

According to Doctor Hawley, one-half of the operations in the United States today are performed by doctors "who are untrained, or inadequately trained, to undertake surgery. The medical care insurance plan makes its largest annual payments for surgery to practitioners without proper qualifications."

In other comments, Doctor Hawley pointed out that only a few health care plans give high quality. Said Doctor Hawley "one of the phenomena in medical care is the confidence placed by the average patient in a license to practice medicine and surgery. Too many patients regard this license as evidence of competence in every aspect of medical care."

Continued Doctor Hawley, "only the few existing plans combining prepayment with group practice have been successful in providing medical care of high quality" because "they select the physicians who give the medical care. Too many of the public are not competent to make an intelligent choice."

HIP Director Describes Effective Medical Care Program.—David P. Barr, M.D., President and Medical Director of Health Insurance Plan of Greater New York, presented the following description of what he considered effective medical care. Said Doctor Barr, "a plan in which prepayment is for service rather than indemnity can offer greater satisfaction to subscribers, greater scope, continuity, and a high quality of care." He said group organization is most important and should be a "true community of interests with pooling and sharing of knowledge, experience and equipment as well as income."

Weakness in Health Coverage Plans Noted.—Dr. Franz Goldmann, formerly of Harvard's School of Public Health, in addressing the GHAA noted that most present health insurance programs do not meet all health needs. He referred to lack of the following as weaknesses in present health insurance programs: Psychiatric care for diagnosis and short-term treatment; Dental service, at least for maintenance care, if not for wider services; Health care for "senior citizens"; Diagnostic and visiting nurse services in Blue Cross plans and extension of hospitalization with full service benefits; "More emphasis on prevention through early diagnosis and prompt and thorough treatment, including medical rehabilitation, 'the front line of attack on dependency' "; "More administrative research, including evaluation of the performance of specific types of plans and assessment of their end results and value."

Doctor Goldmann pointed out to GHAA delegates one reason why these needs are still outstanding is the popular idea that health insurance is not an organized program of medical care but a financial arrangement for payment of certain medical bills.

According to Doctor Goldmann, other reasons frequently given are lack of actuarial basis for extending benefits, lack of demand for them, problems on scope of coverage, and high costs.

Medical Goals Listed.—According to Frederick, D. Mott, M.D., Executive Director of Community Health Association, Detroit, Michigan, "the backbone of good group medical practice" is competent, highly motivated doctors.

He listed the following inducements to attract top caliber doctors: Opportunity for professional growth; provision for medical research; well-equipped group centers; satisfactory remuneration; teaching atmosphere; good supporting staff; availability of a good hospital; and non-salary benefits.

IS THE COST OF MEDICAL CARE TOO HIGH?

Why medical costs are high, as well as what you get today for your medical care dollars, are stories that should be told in a positive way to the American public.

This was the consensus reached by a group of individuals representing medicine, the hospital and pharmaceutical fields, labor, the insurance industry and the ministry at the A.M.A.'s 1959 PR Institute in Chicago.

At the Institute in Chicago's Ambassador West Hotel an entire morning was devoted to a session to determine whether medical care costs are actually too high.

Labor Costs Boost Hospital Costs

Staged in the style of a congressional committee hearing, the session, which was moderated by George Cooley, Secretary of A.M.A.'s Council on Medical Service, heard testimony from the following:

Ray Brown, Director of the University of Chicago Clinics, pointed out that hospital costs rose from an average of $9.39 per patient a day in 1946 to $28.17 in 1958, chiefly due to increased labor costs. Brown pointed out that since hospitals operate a service business, automation does not effect any saving, and wage increases cannot easily be absorbed. There is little chance, Brown said, that hospital costs can be reduced much. Consequently, the medical and hospital professions must talk positively about the forces responsible and explain to the public the advances purchased by the legitimate increased cost.

Public Demands Greater Service

Leonard Martin, Assistant Director of A.M.A.'s Economic Research Department, testified that even though today the patient gets more for his money in terms of diagnosis and treatment, medical cost will always be a factor because people invariably want more service. Stressing that deterioration in hospital care would bring on socialized medicine, Martin said if everyone could be insured for hospital care, people wouldn't be concerned about medical care cost.

Medical Care Produces Top Results

Fred Roll, Director of Public Relations for Smith, Kline & French, Philadelphia, said that while more money is being spent on medical care, top results are being obtained. New drugs are responsible for great advances; the public does not think drugs are expensive "if they work," Roll said. Today's average prescription price is under $3.00 but the entire health team must make personal explanations of this fact and the fact that drugs are high risk products to the public.

Broader Voluntary Health Insurance Coverage

Lawrence Wells, Director of Promotional Activities for Blue Shield Medical Care Plans in Chicago, said survival of voluntary health insurance depends upon performance of Blue Shield—and extension beyond groups, inclusion of senior citizens, broader coverage and comprehensive public education in regard to indiscriminate demands. Economic understanding is vitally needed in regard to what insurance can and cannot do, Wells said, and he urged the medical profession to take the initiative in conducting such an educational campaign to assure continued free enterprise in medicine.

Insurance Industry Offers Cooperation

Arthur Browning, Vice President in Charge of Group Insurance for the New York Life Insurance Company, testified that the health insurance industry is ready and willing to cooperate with the medical and hospital fields to let the public know what the true cost of medical care is. He said the public continually demands broader insurance programs and pointed out that rates must change with changes in service. A recent survey showed that people were more concerned with what they were getting than what they were paying. Browning said abuses of insurance are great in the proprietary hospital field. Since doctors control ninety-five per cent of these hospitals, the medical profession must determine what is going on, especially in big population areas, and correct these abuses.

Unions Want Medical Care "Price Tag"

James Brindle, Director of the Social Security Department for the United Auto Workers in Detroit, said the unions want a price tag on medical care and would like to see organized medicine take the lead in providing service insurance programs. Other indefinite types are unsatisfactory and vague. He also said medical policies should be more medically oriented and added that doc-

tors must run medical insurance programs. Although unions do not like the deductible features in insurance policies, Brindle said Americans have not yet hit the limit in the amount of wages which people will allocate for medical care if the policy offered is good.

Many Questions—Same Answer

In the question period, Dr. L. M. Lichter brought out the fact that insurance abuse is difficult to measure but that in Michigan 75 per cent of the physicians believe the profession is capable of solving this and related medical economic problems. He said the Michigan State Medical Society has set up a referral committee to handle such matters and to settle them fairly for all concerned.

Dr. Donald Harrington, President of the Foundation for Medical Care, San Joaquin County Medical Society, Stockton, California, outlined the San Joaquin County Medical Society's owned and operated Foundation of Medical Care. This organization of participating doctors sets up health insurance contracts, and maintains a claims office for medical review on a local basis.

Doctor Russell L. Deter, Chairman of the Committee on Voluntary Health Insurance and Health Care Costs of the Texas Medical Association, El Paso, Texas, explained the new program being set up by the Texas Medical Association to reduce insurance abuses and Mr. Milo J. Vondracek, Secretary of the Rock River Methodist Foundation, Chicago, suggested the following means of communicating the cost story to the public: letters to county medical societies outlining the problems in the health insurance field with requests for help; educational exhibits; an A.M.A.-produced film for national showings; editorials and fillers for medical society journals; county society symposia; presentation of information on the problem before Medical Student Days programs in orientation programs for new medical society members; and establishment of committees to handle cost and abuse problems.

NOW IT'S PRESCRIPTION INSURANCE

Another experiment in pre-paid care started in March, 1958, in Essex County, Ontario, when Prescription Services, Inc., began as the first known pharmaceutical prescription plan in Canada. It serves an area with a population of 200,000, and agreements with all but seven of the seventy-five pharmacies involved have been signed. A progress report on the first six months shows that of 548 persons enrolled in the last month 104 had 211 prescriptions filled with an average ingredient cost of $1.86 and average retail price of $3.72. Organized labor has been favorable to the new plan, but management has been frank in its opposition to providing another fringe benefit for employes. Sponsors believe that the plan can succeed with slight modifications.

MEDICAL TESTIMONY PLAYS MAJOR ROLE IN "PILL BILL" SUIT

Medical testimony played a major role in a significant legal battle which was in progress in Minneapolis during September and October, when ten members of the Minnesota State Association took the stand to describe the dangerous properties of over-the-counter drugs and medicines.

During the course of a lengthy trial in Hennepin County District Court, where the State made its most recent attempt to halt the sale of drug products by Red Owl, Inc., a supermarket food chain and Groves-Kelco, Inc., a wholesale jobber, medical witnesses testified on the deleterious effects of ingredients contained in over-the-counter preparations and cited instances of harm resulting from their use.

Dr. Haddon Carryer, Head of the Allergy Section, Department of Internal Medicine, Mayo Clinic, described aspirin as a frequent cause of severe allergic reactions and gastro-intestinal bleeding. Acetophenitidin, an ingredient of an aspirin compound involved in the case, is frequently responsible for hemoglobinemia, he said.

Deleterious effects of aspirin on the blood were brought out in testimony by Dr. Howard L. Horns, Minneapolis specialist in hematology and former assistant dean of the University of Minnesota School of Medicine.

Among these effects, he said, is the production of prothrombin, a substance associated with the formation of blood clots. Doctor Horns also stated that in patients under treatment with anticoagulant drugs, aspirin can upset the coagulation balance to the point where serious hemorrhage might result.

Questioned concerning Bromo Seltzer, Doctor Horns said that acetanalid, one of the principal ingredients of this product, may produce hemoglobins which are incapable of carrying oxygen.

Acetanalid may also result in a depression of

the white count in certain individuals, he said, leaving them peculiarly susceptible to infection.

Complications resulting from the use of certain oil-base preparations were described by Dr. John F. Briggs, Saint Paul, who is Chairman of the Section on Diseases of the Chest of the American Medical Association.

In testifying on Vicks cough syrup and Va-tro-nol, he said a drop of oil lodging in the lung as the result of the use of such products can cause oil pneumonia and tumor of the lung.

Dr. J. A. Bargen, Chairman, Department of Gastroenterology, Mayo Clinic, referred to the findings of a nine-year research study in his testimony concerning laxatives. In a group of 265 patients observed during this period, all of whom were long-time users of laxatives with histories of digestive difficulties, he said twenty-seven had undergone a permanent change in the structure of the colon. In these cases, he explained, the haustura had disappeared, resulting in a condition which can be mistakenly diagnosed as colitis.

Dr. Leon Harris, Minneapolis ophthalmologist, said that his clinical experience indicates that prolonged use of Murine eye preparation can result in conjunctivitis.

Dr. Raymond N. Bieter, Head of the University of Minnesota Department of Pharmacology testified at length on the deleterious effects of acetanalid, yellow phenolphthalein and other ingredients found in products which figure in the case.

In testimony concerning incidence of accidental aspirin poisoning, Dr. Richard Raile said that Minneapolis General Hospital, where he is chief of Pediatric Service, recorded 262 cases, one resulting in death, between 1955 and 1956.

Dr. Robert D. Semsch, a Minneapolis pediatrician who is associated with both local and state poison control centers, expressed his belief that information on ingredients and directions for use accompanying many over-the-counter drug products are inadequate for the protection of public health and that labeling does not include sufficient data on contraindications.

During the course of the trial, the defense repeatedly protested that the state had failed to produce evidence of specific instances of harm resulting from the products involved.

On October 7, Dr. Harry Bell, Duluth, took the stand to describe in detail his treatment of a two-and-half year old boy who was brought to him with severe abdominal spasms after ingesting Ex Lax in a Red Owl supermarket.

He was followed by the patient's mother who testified that she placed the chocolate-flavored laxative, which she said she obtained from a self-service rack, in the grocery cart in which the youngster was riding. While she was occupied at a nearby counter, the boy consumed half the contents of the package, she said.

At another point in the trial, Dr. Orley Foster, Minneapolis, related the history of a patient whose condition he diagnosed as bromide poisoning resulting from the habitual use of Bromo Seltzer.

The products involved in the testimony given by these medical men were Murine, Anacin, Alka Seltzer, Bromo Seltzer, Bufferin, Lysol, Pinex, Vicks cough syrup, Va-tro-nol, Aspergum, Aspirin compound tablets, Bromo Quinine, 4-Way Cold Tablets, Pepto-Bismal, Feen-A-Mint, Sal Hepatica, Castoria and Ex Lax.

Representatives of the manufacturers of these preparations came from various parts of the country to observe the proceedings in the Minneapolis court room. This group of spectators included Dr. Frederick G. Cullen, former executive vice president of the Proprietary Association and currently the chief Washington, D. C., lobbyist of that organization.

The lawsuit is regarded as a test case which will establish a precedent of vital significance not only in Minnesota but in other parts of the country where the unregulated sale of drugs and medicines is being opposed.

The defense rested its case largely upon the argument that the products in question are free from regulation by the Pharmacy Board under the provision of the Pharmacy Act which exempts "harmless, non-habit forming, proprietary medicines when labeled in accordance with the requirements of the state and federal Food and Drug Act."

Medical testimony was vital to the support of the State's contention that the products are potentially harmful and that their unregulated sale endangers public health, according to William W. Essling, assistant state attorney general who presented the case for the state.

Beldin H. Loftsgarten represented the Minnesota State Pharmaceutical Association, which intervened in the case on behalf of the State.

Public Health

AN APPRAISAL OF AIR POLLUTION IN MINNESOTA

For some time, the Minnesota Department of Health has been aware of an increasing interest and concern regarding present and potential air pollution problems in Minnesota. To determine the extent of this problem, the Department's Division of Environmental Sanitation, with co-operation from the U. S. Public Health Service, took the first step in a state-wide appraisal of air pollution in Minnesota on October 1.

The objectives of the survey are to assess the nature and extent of air pollution in the State, to inventory and summarize existing State and local legislation relating to air pollution and to assess the present air pollution activities in the State. These data will provide a basis upon which the State or local agencies may determine the type of legislation which would be most suitable and a basis upon which they may determine the type and extent of activities that should be undertaken.

The survey will be conducted through interviews and questionnaires with public and private officials and through field visits to appropriate communities in the State. Data from previous studies and on population and industrial growth, fuel use, topography and climatology and on refuse disposal practices will be compiled and analyzed. Air quality measurements will be made on a limited scale.

Questionnaires have been sent to appropriate municipal officials and to other agencies in the State that might have a knowledge of how air pollution is affecting their area. Persons receiving the questionnaire are urged to return them as soon as possible so that they may serve as a basis for further survey planning. Personal visits will be made to as many communities as possible in all areas of the State with priority given to areas where recognized problems exist.

It is expected that the survey will be completed in about six months and that the report on an Appraisal of Air Pollution in Minnesota will be available for distribution next fall.

DISABILITY DAYS IN THE UNITED STATES

As a result of illness and injury, workers with family incomes under $2,000 per year lost an average of 10.3 days from work during the twelve months ending June 30, 1958, as compared with a loss of 5.9 days for those in families earning $7,000 and over, according to findings of the U. S. National Health Survey of the Public Health Service.

An inverse relationship existed also between income and other forms of restricted activity, such as days in bed due to illness and injury.

Workers sixty-five years of age and over lost about eleven days from work compared with 8.4 days for those in the forty-five to sixty-four year group and 6.3 days for those aged seventeen to forty-four.

City children lost 9.0 days from school, on the average, as a result of illness and injury; rural nonfarm children lost 7.8 days; and farm children lost 7.3 days. However, farm children fifteen and sixteen years of age lost about 10 days from school as compared to 6.5 days lost by urban children of these ages.

This information appears in the latest of a series of published statistical reports issued by the U. S. National Health Survey. The data apply to the total civilian population of the country, exclusive of persons confined to long-term institutions.

Respiratory illnesses, as a group, were the leading cause of activity restriction. They were responsible for 40 per cent of all activity restriction and half of all days in bed. The totals for this group of diseases were affected by the Asian influenza epidemic, but even in a normal year the respiratory diseases are likely to head the list.

Circulatory diseases, including heart disease, ranked second in terms of total volume of disability, followed by injuries and their chronic effects, with digestive diseases running a close fourth.

The data are derived from the continuing nationwide household interviewing with a representative sample of the population, conducted for the Public Health Service by the U. S. Bureau of Census. The information recorded about individuals is confidential and only statistical totals are published.

Editor

LISTEN TO YOUR PATIENTS

"My physician doesn't let me know what's the matter with me," was one of the most common complaints heard by those persons who staffed the Medical Association's booth at the 1959 Minnesota State Fair.

"Listen to your patients," is the advice given by Dr. Jacob H. Conn in the May, 1959 issue of the *Maryland Medical Journal.*

According to Doctor Conn, psychobiologic therapy is a collaboration between physician and patient, each learning from the other. It can never be patterned after a preconceived plan, but must always be modified and adapted to a specific patient's needs in a particular life situation. The patient usually comes to the doctor convinced that his abdominal distress or cardiac dysfunction is due to only one possible cause—a disturbance of organic functioning, totally unrelated to his way of life.

The need to talk is basic. Next to bodily activity, talking is the best method of alleviating tensions. It gives the patient the opportunity to discharge pent-up feelings and provides him with a sympathetic listener, the physician, upon whom he depends for understanding and guidance. Treatment, therefore, begins by the physician's listening to what has gone wrong. It literally is a form of auscultation, and like auscultation of the heart sounds, one must pay particular attention to everything that is heard. It is impossible to present a list of fixed rules that can be used in this phase of psychotherapy. The following general principles will be of assistance:

(a) *Listen patiently to what the patient is saying.* It gives him a feeling that you are genuinely interested in him as a person.

(b) *Do not interrupt when he seems to talk of inconsequential trifles.* There is no such thing as irrelevance in a patient-physician interview. The patient is expressing his feelings as well as talking about facts.

(c) *Think along with the patient.* Ask yourself not only what is he saying but how he is saying it, and why does he say what he does at this particular moment? Does he need sympathy? Is he misinformed? Does he feel guilty, and therefore is seeking reassurance? Is he angry, afraid, sad or evasive as he approaches a sensitive personal topic?

(d) *Show a real interest and personal warmth in what is going on.* Ask for more details, examples, or amplifications of what already has been stated in outline fashion. Ask, "Then what happened?" "So?" "And then," or more pointedly, "Why?"

(e) *Avoid criticism and argumentation.* The patient can accept only a part of what you feel or know to be the whole truth. He has been deceiving himself over a long period of time and is not able to see himself as objectively as others may see him. Therefore, never tell him he is "neurotic" or that "nothing is wrong" or that he is "seeking sympathy."

IS MEDICINE ON THE RIGHT TRACK?

Today, there are many individuals and groups who are challenging the devoted public-service minded intentions of the American man of medicine. Not infrequently his doctor-patient relationship is in danger because of constantly changing public attitude toward him and the art which he practices.

These transitions may be reflected in legislation, the cost of medical care, and attitudes toward aging to mention a few. Because it is essential that the individual physician stay abreast of these changes and proceed accordingly, the American Medical Association annually sponsors a Public Relations Institute for state and county medical society executives and public relations personnel.

Setting the stage for the opening session of AMA's 1959 Public Relations Institute at Chicago's Ambassador West Hotel, August 20 and 21, Leo Brown, Director of AMA's Communications Division, asked two vital questions:

Is medicine on the right track?

Is the non-scientific side of medicine keeping pace with scientific advancement?

Brown said this is a question other groups and institutions also are facing in this space age.

"Caught in the cross-currents of conflicting political and social philosophies, organizations as well as nations are finding it necessary to reassess their positions and their policies."

Medicine Faces Many Challenges

"Medicine finds itself once again fighting 'socialized medicine'—this time wearing the garb of a social security hand-out," Brown said. "The possibility that this legislation may succeed is a very real one. The medical profession cannot afford to be a pufferbilly engine, chugging along lazily, impervious to the upheavals in the world around it."

The alert, progressive and public-service minded men of medicine should be challenged by the problems of today, he pointed out. In addition to defeating legislation that threatens to undermine America's fine medical care system and educating people again to the excellence of our democratic free choice system, it is time for medicine to take more intense interest in what people say are the problems in the health field.

"Many a piece of legislation stems from what politicians claim is a 'desperate need.' Well, let's find out if there *is* such a need. If there is, let's *do* something constructive about it. If there isn't, let's *tell* people about it."

Creative Thinking Necessary

Brown said medicine has the solutions to many of its current problems within its own hands. Physicians must do some creative thinking about the route medicine will travel in the years ahead and activate the men in the profession to play a more active role in developing resourceful programs and providing more community leadership.

"Better to be an engineer on the medical train, carrying the responsibility for the safe passage of those aboard, than the brakeman on the caboose, waving the flag too late," Brown said.

He concluded that probably no professional group is less selfishly motivated but is more criticized for selfish interest than the medical profession. He said community service is one important way medicine can identify itself with public interest rather than selfish interest.

HEALTH EDUCATION FILMS

Medical societies are frequently asked to recommend health education films suitable for showing to school and church groups. Motion pictures are also needed to be shown as presentations before civic groups at health fairs or at special events.

Write to the state office for your listing of selected motion pictures on health education subjects. Many films contain current information and can be obtained without charge (other than return postage).

Minnesota Blue Shield-Blue Cross

The Minnesota Blue Shield claims load continued to increase during the first eight months of 1959. Approximately 225,000 medical service reports were processed by Blue Shield during the first eight months of this year, an average of over 28,000 reports each month and a working day average of nearly 1,300 reports. Less than 10 per cent of these reports were ineligible for payment or were forwarded to other Blue Shield Plans, but even these claims required some processing.

Blue Shield payments to physicians during these eight months totaled $6,878,999. This figure is equal to monthly average payments of nearly $860,000 and far surpasses the total amount paid physicians in the same period of any previous year. During the first eight months of 1958 Blue Shield paid $6,476,003 for physicians services rendered participant subscribers or $402,996 less than was paid during the first eight months of 1959.

A total of 260,457 doctors' services were represented in Blue Shield payments from January 1 through August 31 of this year. This figure is 19,000 services greater than the number of services (241,458) which were provided Blue Shield benefits during the same eight months of 1958.

Minnesota Blue Cross hospitalization expense incurred during the first eight months of 1959 exceeded $25,1000,000, an increase of over $2,800,000 compared to hospitalization expense incurred during the same period of the previous year. This increase is a reflection of increased subscriber usage of Blue Cross benefits, hospital per diem costs and trend of the conversion of Blue Cross subscribers toward the higher benefit levels of coverage.

The 927,637 days of hospital care provided 147,691 Blue Cross subscribers and dependents during the first eight months of 1959 represented 3.2 days paid per year per 1,000 contracts protected, approximately 3.0 per cent over the 3.1 days per year per 1,000 contracts provided during the same period of the preceding year. The number of Blue Cross subscribers and dependents hospitalized and length of hospital stay incurred because of accidental injuries and neoplasms contributed the major portion of this increase in usage. It is interesting to note that through the first eight months, Blue Cross subscribers and dependents have been hospitalized because of diseases of the respiratory and digestive systems less frequently than during the same period of the preceding year.

Communications

A NEW EPIDEMIOLOGICAL STUDY OF CANCER

As reported in the July 11, 1959, issue of the *Journal of the American Medical Association,* the American Cancer Society is undertaking a large-scale study of cancer in relation to various environmental factors. Considering what is already known about causes of cancer in human beings, and considering the circumstances which led to their discovery, there is reason to suspect that many cases of cancer result from exposure to environmental factors not yet identified as carcinogenic for human beings. Once these factors are determined, there is hope of preventing the disease by reducing exposure to the responsible agents just as analine dye workers are now protected from exposure to beta naphythylamine to avoid the risk of bladder cancer.

One approach to the problem is to learn as much as possible about the environment, habits and family history of a very large number of people and then ascertain the later incidence of cancer in relation to these factors. By starting with a population of several hundred thousand people in all walks of life, the number of individuals falling into specific exposure groups should be sufficient to yield reasonably reliable cancer incidence rates. If any of these groups has an unusually high incidence of cancer at some specific site, then further studies can be undertaken to determine whether a direct causal relationship exists.

This is the basis for a new prospective epidemiological study being undertaken by the American Cancer Society under the direction of Dr. E. Cuyler Hammond, ACS Director of Statistical Research. It may be described briefly as follows:

Several hundred counties in 25 states, including Minnesota have been selected as study areas. The selection was made in such a way as to give a satisfactory geographic distribution. Cities of various sizes and types as well as rural areas will be included.

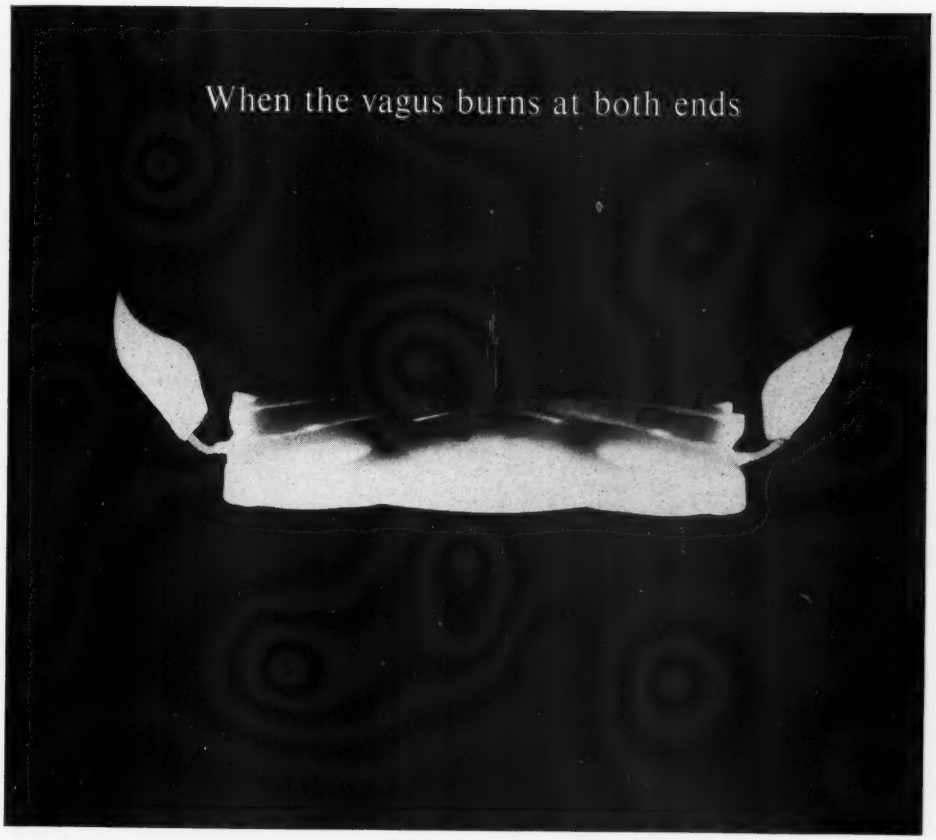
The plan is to enroll about 500,000 families nationwide of which about 20,000 families will be enrolled in Minnesota beginning on October 15, 1959. Volunteer workers of the Minnesota Division of the Society will be used to enroll families in which there is at least one person over the age of 45 and then request every member who is over the age of 30 to fill out a questionnaire. In order to keep the information confidential, each subject will put his filled-out questionnaire in an envelope and seal it before returning it to the volunteer for transmittal to the research center. The volunteers will not interview the subject and will not see the completed questionnaires.

The subjects will be followed annually for six years to determine which of them die in this interval. Causes of death will be ascertained from death certificates (not from the family). When cancer is mentioned on a death certificate, the physician who reported it will be requested to supply additional medical information (e.g., histologic type, stage of disease at time of diagnosis, etc.).

The major purpose of the study is to ascertain the association, if any, between various environmental factors (such as occupational exposures, habits, diet, factors related to the breast and female genital organs, etc.) and the later occurrence of cancer. It is hoped that this will yield clues as to a number of possible causes of cancer.

In addition, it is hoped that the study will provide information of value in relation to lay education. The subjects are asked detailed questions about "present physical complaints" and the answers will be analyzed in relation to cases of cancer diagnosed in the subsequent several months. In order to avoid biasing the subjects, questions are asked about physical complaints which are probably not related to cancer as well as about complaints which may be symptomatic of cancer. Assuming, as is probable, that positive answers to certain of these questions are highly related to the presence of cancer, the data later should be of value in persuading people with such complaints to see their doctor immediately. The aim, of course, is to reduce the factor of "patient delay" in the diagnosis of cancer.

FRANCIS W. LYNCH, M.D.



This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

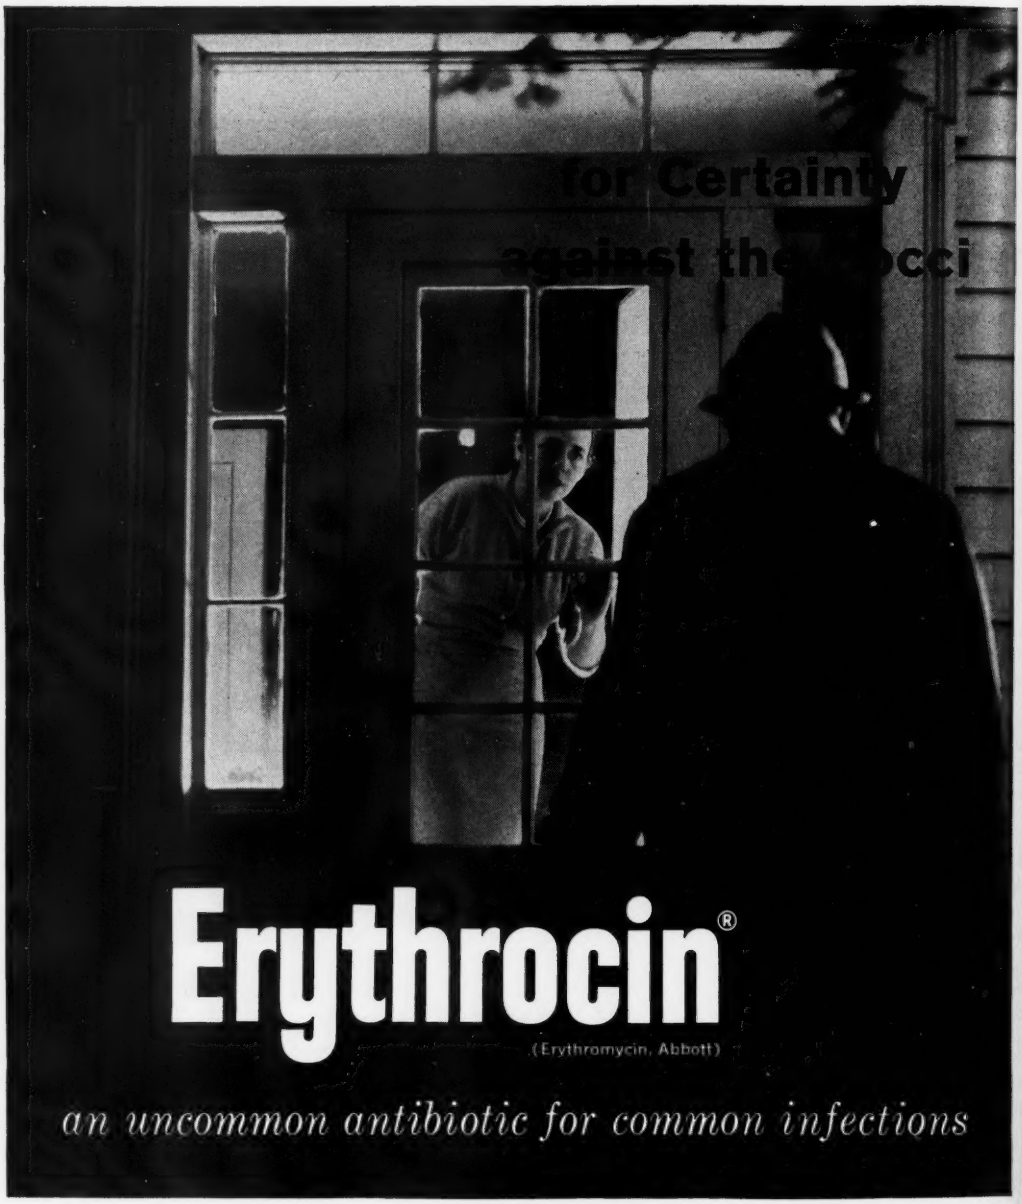
THE TUMOR REGISTRY

The value of the Tumor Registry maintained at each local hospital in Duluth has been questioned by many physicians. The criticism that the treatment of cancer is not influenced by these data may be valid at the present time. However, in spite of incomplete records, variations in therapeutic methods between physicians, patients lost to follow-up, et cetera, the future value of these data may be beyond our ken. The most pessimistic critics of the Tumor Registry state that our present methods of treatment fail to alter the course of carcinoma of the stomach, breast and lung. This latter objection, if true, suggests one fundamental series of observations not now available: the natural history of cancer in various organs.

Unless the most optimistic physicians envision a lytic agent which will destroy all malignant cells and omnisciently spare the normal, then future life-saving methods of cancer therapy will require a base line of experience against which the value of each agent may be measured. If each local Tumor Registry can contribute to such a base line of experience and document the natural history of malignant disease, then these data alone should be ample justification for the careful collection and tabulation of each cancer case by the Tumor Registry method.

J. V. THOMES, M.D.

Pro-Banthine® with Dartal® moderates both mood and gastrointestinal spasm



The slow simmer of anxiety frequently causes kindred gastrointestinal overactivity. The spasticity and the accompanying distress of excess acid lead to loss of efficiency. Patients subject to such psychoenteric upsets require therapy to calm both ends of the vagus.

Pro-Banthine with Dartal contains two agents required for such dual therapy: Pro-Banthine to control and curtail the flare-ups of spasm, excess acidity and excess motility, and Dartal to smother simmering anxiety and tension.

Pro-Banthine with Dartal contains 15 mg. of Pro-Banthine (brand of propantheline bromide) and 5 mg. of Dartal (brand of thiopropazate dihydrochloride) in each tablet.

Dosage: One tablet three times a day.

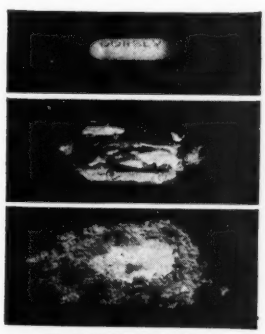
EYES IN INDUSTRY COURSE ANNOUNCED

The Institute of Industrial Health of the University of Cincinnati announces a course of instruction in *Industrial Eye Problems* will be given during the week of January 18-22, 1960. It will be presented by the Institute of Industrial Health in cooperation with the Department of Ophthalmology.

Current concepts regarding vision requirements for specific job categories will be discussed. Eye examination procedures and vision screening devices will be demonstrated. Opportunity for informal discussion of practical problems will be provided.

Physicians interested in attending the course should write for an application blank to: A/60, Institute of Industrial Health, Kettering Laboratory, Eden and Bethesda Avenues, Cincinnati 19, Ohio. The registration fee will be $100.

(Continued on Page 1656)



MAINTENANCE THERAPY WITHOUT STEROIDS IS FUNDAMENTAL

Sound, conservative therapy with salicylates has been consistently reaffirmed as basic, long-term maintenance therapy in the arthritides.

Buffered Pabirin provides superior maintenance therapy. It epitomizes fundamental long-term basic therapy since it can be given month after month without serious complications and with minimal problems to patient and doctor alike.

Buffered Pabirin is formulated to provide high and sustained salicylate blood levels. Each tablet consists of an outer layer containing a buffer (aluminum hydroxide), para-aminobenzoic acid, and ascorbic acid; a core of acetylsalicylic acid.

In the stomach, the outer layer quickly releases the buffer, which protects against nausea, dyspepsia and other gastrointestinal symptoms so frequently encountered with salicylates alone. The core of Buffered Pabirin then disintegrates rapidly, permitting rapid absorption of the acetylsalicylic acid for faster pain relief.

Photographs show 2-stage Tandem Release disintegration.

Each tablet contains:
Acetylsalicylic acid (5 gr.).....300 mg.
Para-aminobenzoic acid (5 gr.)....300 mg.
Ascorbic acid ..... 50 mg.
Dried aluminum hydroxide gel....100 mg.

All Buffered Pabirin is sodium- and potassium-free.

Dosage: Two or three tablets 3 or 4 times daily.

PRIZE ESSAY CONTEST FOR MEDICAL STUDENTS ANNOUNCED

The American College of Chest Physicians is offering three cash awards to winners of the 1960 Prize Essay Contest. First prize, $500.00—second prize, $300.00—third prize, $200.00. Each winner will also receive a certificate.

The contest is open to *undergraduate* medical students throughout the world. Essays may be written on any phase of the diagnosis and treatment of chest diseases (cardiovascular or pulmonary).

The contest closes on April 1, 1960. For application and further information, please write: American College of Chest Physicians, 112 East Chestnut Street, Chicago 11, Illinois.

FELLOWSHIPS FOR STUDY OF ARTHRITIS AND RELATED DISEASES

The National Foundation announces the availability of fellowships for clinical study in arthritis and related diseases for physicians who have an interest in rheumatic diseases and who intend to apply their knowledge of these diseases to clinical service, teaching, or research.

Only physicians, licensed, or eligible for licensure, to practice in the United States and who have had at least two years of specialty training acceptable to the appropriate American Board (or equivalent training) are eligible. All applicants must be United States citizens.

Financial support for the Fellow is $4,500.00 a year with $540.00 allowed annually for each dependent. Annual increases of $480.00 are ordinarily granted. Under unusual circumstances higher stipends may be permitted. For a full academic program, complete tuition and fees are paid; for other programs, a sum not to exceed $1,250.00 including tuition may be arranged.

Applications must be received by:

February 1 for consideration approximately May 1, 1960.

August 1 for consideration approximately November 1, 1960.

November 1 for consideration approximately February 1, 1961.

The National Foundation has authorized the expenditure of $33,400,000 since 1938 for professional education.

For further information, write to: Division of Scholarships and Fellowships Department of Professional Education, The National Foundation, 800 Second Avenue, New York 17, New York.

NEW PUBLICATION

The Society of Nuclear Medicine, 430 North Michigan Avenue, Chicago 11, Illinois, is pleased to announce the forthcoming publication of its official organ, *The Journal of Nuclear Medicine*. The first quarterly issue will appear during the month of January, 1960.

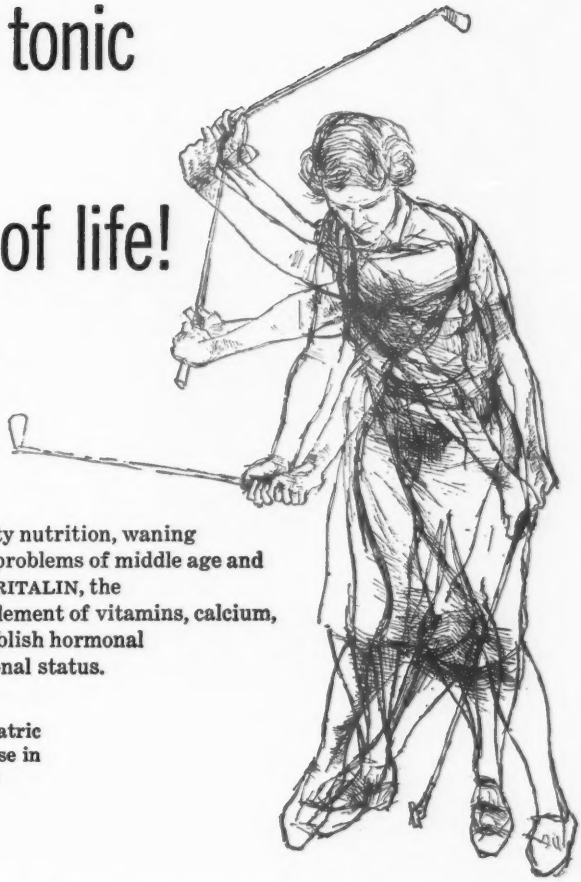
Annual Clinical Conference

CHICAGO MEDICAL SOCIETY

March 1, 2, 3 and 4, 1960

Palmer House, Chicago

Daily Half-Hour Lectures by Outstanding Teachers and Speakers on subjects of interest to both general practitioner and specialist.



Panels on Timely Topics — **Teaching Demonstrations**

Medical Color Telecasts — **Instructional Courses**

Scientific Exhibits worthy of real study and helpful and time-saving Technical Exhibits.

The Chicago Medical Society Annual Clinical Conference should be a MUST on the calendar of every physician. Plan now to attend and make your reservations at the Palmer House.

New revitalizing tonic brightens the second half of life!

Ritonic™

A sense of frustration and inadequacy, faulty nutrition, waning gonadal function—RITONIC meets all these problems of middle age and senile let-down. The unique combination of RITALIN, the *safe* central stimulant, with a balanced complement of vitamins, calcium, and hormones acts to renew vitality, re-establish hormonal and anabolic benefits, and improve nutritional status.

"We found Ritonic to be a safe, effective geriatric supplement . . ."[1] "Patients reported an increase in alertness, vitality and sense of well being."[2]

PRESCRIBE RITONIC

for your geriatric patients, your middle-aged patients and your postmenopausal patients.

Each Ritonic Capsule contains:

Ritalin® hydrochloride	5 mg.
methyltestosterone	1.25 mg.
ethinyl estradiol	5 micrograms
thiamin (vitamin B_1)	5 mg.
riboflavin (vitamin B_2)	1 mg.
pyridoxin (vitamin B_6)	2 mg.
vitamin B_{12} activity	2 micrograms
nicotinamide	25 mg.
dicalcium phosphate	250 mg.

Remember

TV SHOW ABOUT HUMAN SENSES

What science has learned about the operation of the human senses will be seen again on television Sunday afternoon, December 6, at 5:00 p.m., on KSTP-TV Twin Cities, when "Gateways to the Mind" on the Bell System Science Series will be given a repeat telecast over NBC-TV. Viewers in other areas are advised to consult local program listings. The program was first seen on October 23, 1958.

With Professor Frank C. Baxter of the University of Southern California as narrator, the hour-long program uses both documentary film and animation to explain the functions of the sense organs and their connections with the brain. The program is presented in both color and black and white.

Of particular interest to the medical profession is the guest appearance of Dr. Wilder Penfield, McGill University surgeon, to show his experiments in eliciting sensation by direct stimulation of brain areas.

Dr. Hadley Cantril, Princeton University psychologist, appears on the program to explain his experiments in illusions. Experiments in the deprivation of sensory stimulation are also shown.

"Gateways to the Mind" was produced under the technical supervision of Dr. George Wald, professor of biology at Harvard, and Dr. Frederick Crescitelli, professor of zoology at UCLA, and an advisory board of ten leading American scientists.

Bell Telephone Companies throughout the country are making the program available on 16-mm. color film for showings to interested groups.

ASIA-PACIFIC ACADEMY OF OPHTHALMOLOGY

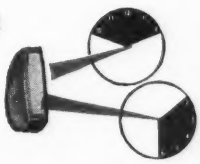
The First Congress of the Asia-Pacific Academy of Ophthalmology will be held in Manila, Philippines, from October 10 to 13, 1960, under the sponsorship of the Philippine Ophthalmological Society. This will be participated in by delegates from different countries of the Asia-Pacific regions and also by guests from the Americas and Europe. Its main theme will be: "Blinding Diseases of the Asia-Pacific Regions."

The Committee on Scientific Program has set February, 1960, as the deadline for the submission of titles of free papers (with brief abstracts of 200 words) and Medical Films, so that these can be included in the official program of the Congress. In addition to these papers and films, there will also be Guest Lectures by prominent ophthalmologists from America, Australia, Europe and India.

For registrations or further particulars, kindly communicate with Dr. Jesus V. Tamesis, Executive Chairman, 42 Quezon Blvd., Quezon City, Philippines.

running noses and open stuffed noses orally

Triaminic®



the leading oral nasal decongestant

- in nasal and paranasal congestion
- in sinusitis
- in postnasal drip
- in allergic reactions of the upper respiratory tract.

safer and more effective than topical medication[1,2,3]

- systemic transport to all respiratory membranes
- provides longer-lasting relief
- presents no problem of rebound congestion
- avoids "nose drop addiction"

Relief with Triaminic is prompt and prolonged because of this special timed-release action . . . beneficial effect starts in minutes, lasts for hours

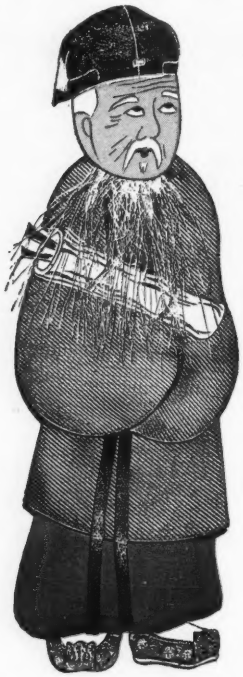
first—the outer layer dissolves within minutes to produce 3 to 4 hours of relief

then—the core disintegrates to give 3 to 4 *more* hours of relief

Each TRIAMINIC Tablet provides:
Phenylpropanolamine HCl .....50 mg.
Pheniramine maleate .....25 mg.
Pyrilamine maleate .....25 mg.

One-half of this formula is in the outer layer, the other half is in the core.

Dosage: One tablet in the morning, mid-afternoon and at bedtime.



References: 1. Lhotka, F. M.: Illinois M. J. 112: 259 (Dec.) 1957. 2. Fabricant, N. D.: E.E.N.T. Monthly 37:460 (July) 1958. 3. Farmer, D. F.: Clin. Med. 5:1183 (Sept.) 1958.

TRIAMINIC JUVELETS: Each timed-release Juvelet is equivalent in formula and dosage to one-half of a TRIAMINIC tablet, for the adult or child who requires only half strength dosage.

TRIAMINIC SYRUP is recommended for adults and children who prefer liquid medication. Each 5 ml. tsp. is equivalent to ¼ of a Triaminic Tablet. *Adults:* 2 tsp. 3-4 times a day; *children 6-12:* 1 tsp. 3-4 times a day; *children under 6:* in proportion.

Woman's Auxiliary

ST. LOUIS COUNTY AUXILIARY

Nursing Scholarships

The St. Louis County Medical Auxiliary has awarded $400 in scholarships this Fall to assist three girls in their nurses' training.

Miss Frances Horvath, 709 12th St. No., Virginia, Minnesota, of the College of St. Scholastica, Department of Nursing, St. Mary's Hospital, Duluth, Minnesota, is the recipient of a $200 scholarship. Twin sisters, Miss Judith and Miss Janith Aili, 822 Celia Street, Ironwood, Michigan, St. Luke's Hospital School of Nursing, Duluth, Minnesota, each received $100.

Dinner Dance

On September 19, the Auxiliary honored their husbands at a Dinner-Dance at the Kitchi Gammi Club. The decorations centered around the forthcoming hunting season, and the gold-painted duck decoys used as table centerpieces were auctioned off to raise a sizable amount for the A.M.E.F.

Membership Tea

The Annual Membership Tea was held on Tuesday, October 13, at the home of Mrs. John F. Schmid. All members, prospective members, and wives of residents and interns were invited to attend.

Northern Minnesota Medical Association Meeting

The wives of doctors attending the Northern Minnesota Medical Association Meeting in Duluth on September 11 were entertained by the local Auxiliary with luncheon at the Kitchi Gammi Club and a tour of the Skyline Drive, the new Port Terminal Building, and other points of interest in the harbor. The theme of the Seaway was carried out in the table decorations and favors.

Mrs. M. F. Fellows, the State Auxiliary President, was a guest speaker. Mrs. John Haavik is president of the St. Louis County Auxiliary and Mrs. Josiah Fuller was Chairman for the women's events.

RAMSEY COUNTY AUXILIARY

The Fall Style Show was both a financial and social success, due to the efforts of committees under Mrs. Phil Roy and Mrs. B. G. Lannin.

Mrs. Hanns Schwyzer, President, entertained Board members at a luncheon in her home in September. Plans were formulated for a tea to be given by the Auxiliary for their members at the home of Doctor and Mrs. Gordon Kamman, on November 19. Past Presidents will be guests of honor.

Many members have taken advantage of the training sessions offered by the Red Cross National Blood Program. Mrs. Charles Froats and Mrs. E. R. Sterner are chairmen of this main project for the coming year.

RAMSEY COUNTY AUXILIARY

(Continued from Page 1660)

Mrs. Ralph Olsen, Cancer society representative, introduced Mrs. Helen Barlow at the October Board meeting. Mrs. Barlow explained the Cancer Research questionnaire which is being started by the National Cancer Society.

STUDENT MEDICAL AUXILIARY

A welcome tea in honor of new members of the Student Medical Auxiliary was held October 25 from 3 to 5 p.m. in Coffman Union, University of Minnesota. Mrs. James Knapp, 6005 W. 35th Street, Minneapolis, state chapter president, presented the welcome.

Special guests included Mrs. M. F. Fellows, state president of the Woman's Auxiliary; Mrs. Frederick Gunlaugson, president of the Hennepin County Woman's Auxiliary; and Mrs. Hans C. Schwyzer, president of the Ramsey County Woman's Auxiliary.

Responsibilities of a doctor's wife were discussed at the November 10 meeting at the home of Dr. and Mrs. C. D. Creevy, 1633 E. River Road, Minneapolis.

The December 8 meeting will be held at the home of Dr. and Mrs. William D. Nesset, 5528 Merritt Circle, Minneapolis. The program will be devoted to making Christmas decorations for homes for the aged.

On December 18 and 19, a rummage sale will be held at 810 S. 10th Street, Minneapolis, with proceeds going to the scholarship fund.

ZUMBRO VALLEY AUXILIARY DISCUSSES RESPONSIBILITIES OF PHYSICIANS' WIVES

Four members of the Zumbro Valley Medical Society Auxiliary recently told 160 wives of Fellows in the Mayo Foundation about the role of the physician's wife in the community and on the "home front."

Mrs. James W. DuShane, moderator, Mrs. Earl C. Elkins, Mrs. Howard P. Rome, and Mrs. Charles F. Stroebel gave a panel discussion, "So You Married a Doctor," at the first meeting of the fall season of the Fine Arts Section of the Magazine Club at the Foundation House.

Using their own experiences as examples, the doctors' wives gave advice.

"Don't spread yourself too thin," was one suggestion. Most communities turn for help to doctors' wives in organizing work on health problems and children's projects. Don't join so many groups you haven't time left for this important aspect of community giving, the panelists cautioned.

Many valuable experiences may be gained by joining church groups first, the speakers said. They agreed that with the time limitations imposed by a doctor's long hours, his wife should never allow community projects to precede her family responsibilities.

The "home front" atmosphere should be one of creativity, with flexible schedules allowing for quiet hours, as well as for family sharing of activities.

A coffee hour preceded the program. Hostesses were Mrs. William M. Michener, chairman, Mrs. F. Richard Dion, Mrs. Ralph B. Johnson, and Mrs. Samuel Weisz.

MINNESOTA MEDICAL FOUNDATION SCHOLARSHIP AWARDED

Twenty-six University of Minnesota medical students won scholarships totalling $13,250 from the Minnesota Medical Foundation for the 1959-60 academic year. Most were for $500.00 each.

The awards, said Dr. Herman E. Drill, Foundation President, brought to $93,500 the total amount given to medical students in scholarships during the past eleven years. There have been 183 separate awards.

The scholarships were conferred at Minnesota Medical Foundation Day exercises September 28 held in conjunction with the opening of the Seventy-first academic year of the University of Minnesota medical school.

Dean Theodore C. Blegen of the University's Graduate School delivered the main address titled "Some Thoughts on the Nature and Meaning of Scholarship." He was introduced by Dr. Wesley W. Spink, former Foundation President and now Professor of Medicine at the medical school.

Dr. J. Arthur Myers, Professor Emeritus at the University's School of Public Health and career tuberculosis fighter, was awarded the Outstanding Achievement Award, highest honor given by the Board of Regents. Doctor Robert B. Howard, Dean of the College of Medical Sciences, conferred the award.

Recipients of Foundation scholarships, some designated by the name of sponsoring organization were: David S. Hopkins, St. Paul, Senior; Michael F. Koch (Minneapolis Guild of Catholic Physicians), Wadena, Senior; Kenneth P. Manick (Minneapolis Gas Company), Minneapolis, Senior; John A. Cich (Modern Medicine), Minneapolis, Junior; Walter D. Cunningham (Minnesota Academy of General Practice), Sturgeon Lake, Junior; Nancy Jo Engeset (Western Oil and Fuel Company), Minneapolis, Junior; James C. Guthrie, St. Paul, Junior; John B. Leary (Minnesota Academy of Medicine), St. Paul, Junior; Robert E. Olson (Erling S. Platou, Nu Sigma Nu), Minneapolis, Junior; and Jonathan A. Parsons (Minneapolis Academy of General Practice), Minneapolis, Junior.

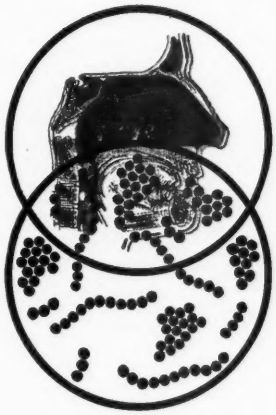
Expansion Plans Announced

Plans for expanding its fund raising and alumni relations programs have been announced by the head of the Minnesota Medical Foundation.

Dr. H. E. Drill, Hopkins, said the Foundation has completed plans to enlist more members and more funds to step up its services to the school. The Foundation, he said, will open its door to greater membership from the general public and will seek the active support of the University's 5,700 medical alumni.

Established in 1939 by medical faculty leaders and alumni, the Foundation now lists 1,200 members and in its first decade has distributed nearly 200 scholarships to medical students, sponsored lectures, published research papers, and held health forums for the public.

In the future, Doctor Drill said, the Foundation will (1) publish reports on the achievements, objectives and needs of the medical school; (2) seek to double its membership; (3) afford specialized liaison services to the school; (4) publish a redesigned version of the University's Medical Bulletin; and (5) work closely with University authorities and the Minnesota Medical Alumni association in fostering close alumni relations.



Eivind Hoff, Jr., newly named the first Executive Secretary in Foundation history, pointed out that plans for future activities were drawn from a survey of needs published by the medical school last winter.

The report detailed such needs as scholarships for medical students; recognition of outstanding teaching or research by faculty members; fundamental research support, building projects and medical student recruitment.

"Planned programs in areas will help the medical school maintain its high rank in medical education," Hoff said. "This is to be the Foundation's major single objective."

when upper respiratory congestion is complicated by bacterial invaders

TRISULFAMINIC provides logical therapy

- for the patient ill with congestion and infection of the upper respiratory tract, as in purulent rhinitis, sinusitis, tonsillitis and otitis media, when caused by sulfa-susceptible bacteria;
- because secondary invasion by such bacteria so frequently follows the common cold.[1]

the reasons for combining Triaminic with triple sulfas

Triaminic and triple sulfas are not only pharmacologically *compatible*, they are a therapeutically *logical* combination for upper respiratory infections: Triaminic for effective decongestant relief from rhinitis, rhinorrhea and sinusitis;[2] triple sulfas for well-established antibacterial action.

The advantages of Trisulfaminic in upper respiratory infections include: proved effectiveness; safety; economy; ease of administration; less likelihood of sensitivity reactions;[3] compatibility with antibiotics and other antibacterial therapy. Provided also as Suspension for additional convenience.

Trisulfaminic®

TRIAMINIC WITH TRIPLE SULFAS

Available as TABLETS and SUSPENSION

Each easy-to-swallow Trisulfaminic Tablet or 5 ml. teaspoonful of Suspension provides:

Triaminic® .....25 mg.
(phenylpropanolamine HCl 12.5 mg.
pheniramine maleate ..... 6.25 mg.
pyrilamine maleate ..... 6.25 mg.)
Trisulfapyrimidines, U.S.P. .....0.5 Gm.

Dosage:

Adults—2 to 4 tablets or tsp. initially, followed by 2 tablets or tsp. every 4 to 6 hours until the patient has been afebrile 3 days. *Children 8 to 12* — 2 tablets or tsp. initially, followed by 1 tablet or tsp. every 6 hours. *Children under 8*—dosage according to weight.

The palatability, convenience and effectiveness of the Suspension make it especially suitable for children and for those older patients who prefer liquid medication.

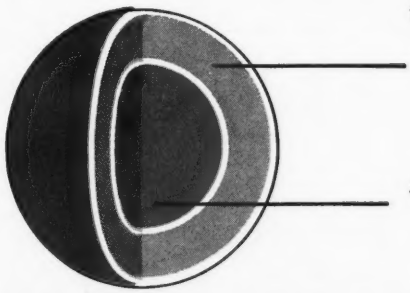
MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

ROSEAU COUNTY HEALER SENTENCED FOR BASIC SCIENCE VIOLATION

On October 13, 1959, Conrad Hanson, fifty-one, Strathcona, Minnesota, entered a plea of guilty before the Hon. Paul Lundgren, Judge of the District Court of Roseau, Minnesota, to an information which charged him with violating the basic science law by maintaining an office for the reception, examination, diagnosis and treatment of persons for diseases, deformities, etc. Judge Lundgren then sentenced the defendant to a term of six months in the Roseau County Jail and to pay a fine of $500. However, the Court, in addition to suspending $200 of the fine, stayed the execution of the jail sentence and placed Hanson on probation for one year. A criminal complaint against Hanson had been signed on July 21, 1959 by a representative of the Minnesota State Board of Medical Examiners after an investigation disclosed that the defendant was treating patients for various physical conditions in his living quarters in the rear of a grocery store operated by him in Strathcona.

When questioned by the Court prior to being sentenced, Hanson stated that he had been in the grocery business for twelve years at Strathcona and that within the past four years he had learned how to treat patients by taking instructions from a healer in Salem, South Dakota. Although Hanson denied that he had charged fees in connection with his healing activities, he admitted that patients left money in the form of donations and that he had kept the money. The defendant also stated that he had made trips to other towns to heal people, illustrating his remarks by saying that he had visited Lockhart and Winger, Minnesota for this purpose. In response to questioning, Hanson admitted that he had attempted to cure patients of such serious ailments as rheumatism, arthritis and heart conditions but he denied that he could cure cancer. Judge Lundgren then cautioned the defendant that one of the terms of his probation required him to refrain from engaging in healing in any manner.



After the defendant's arrest on July 21, 1959, he gave a signed statement in which he said he had been treating from five to fifty patients per day, having seen seventeen that day, by rubbing the feet of the patients and using vibrators. He also stated that he gave out numbers to the patients to enable him to take them in proper order and that he received from 50c to $2.00 for each treatment, the most common amount being $1.00. According to Hanson, he was born on November 24, 1907 in Hues Township near Strathcona and has no education beyond grade school, having taken no scientific training of any kind. The defendant holds no license to practice any form of healing in the State of Minnesota.

From the point of view of the clinical pathologist, the finding of Bence-Jones protein in the serum is so rare, and its correlation with multiple myeloma is so high, that this positive finding imposes on the clinician the burden of proving that the disease in question is not multiple myeloma.

the complaint: "nervous indigestion"

the diagnosis: any one of several nonspecific gastrointestinal disorders requiring relief of symptoms by sedative-antispasmodic action with concomitant digestive enzyme therapy. **the prescription:** a new formulation, incorporating in a single tablet the actions of Donnatal and Entozyme. **the dosage:** two tablets three times a day, or as indicated.

the formula: *in the gastric-soluble outer layer:*

Hyoscyamine sulfate	0.0518 mg.
Atropine sulfate	0.0097 mg.
Hyoscine hydrobromide	0.0033 mg.
Phenobarbital (⅛ gr.)	8.1 mg.
Pepsin, N.F.	150 mg.

in the enteric-coated core:

Pancreatin, N.F.	300 mg.
Bile salts	150 mg.

In Memoriam

CHARLES CURRY BELL

Dr. Charles Curry Bell, St. Paul physician and surgeon, died October 9, 1959. He was seventy-one years of age at the time of his death.

A member of the staffs of Ancker, St. Luke's and St. John's Hospitals, St. Paul, he was also a member of the consulting staff of Miller Hospital.

Doctor Bell was born in Cowley County, Kansas; he was a graduate of the University of Oklahoma, Norman, Oklahoma, and Rush Medical College, Chicago.

He had offices in the Lowry Medical Arts Building, St. Paul, for several years and was active in the practice of industrial medicine.

Doctor Bell was a member of the American Medical Association, the Minnesota State Medical Association, the Ramsey County Medical Society, the St. Paul Surgical Society, the Minnesota Surgical Association, the Clinical Club and the Medical Assembly.

He was a past president of the Ramsey County Sportsmen's Association and a member of the St. Paul Athletic Club, the Masonic Lodge and Central Park Methodist Church.

Survivors include his widow, Violet J.; daughter, Mrs. Nancy Benton, New York City; three sons, Charles C. III, John M. and Richard J., all of New York City; three sisters, Annie E. Bell, S. Josephine Bell and Dr. Mary R. Bell, all of Oklahoma City, and four grandchildren.

THOMAS GRATZEK

Dr. Thomas Gratzek, St. Paul surgeon, died October 9, 1959, at his summer home in Harding, Minnesota. The deceased was seventy-four years of age at the time of his death.

Born in Florian, Minnesota, Doctor Gratzek was a graduate of the University of Illinois Medical School. He spent his internship at Cook County Hospital, Chicago, Illinois. Except for service in the Army Medical Corps in World War I, he had been a physician and surgeon in St. Paul since 1914.

He was a member of the American Legion, VFW Charles F. Skweres Post No. 2817, Polish National Alliance, Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. A Fellow in the American College of Surgeons,

■ Exhibits unusual analgesic properties, different from those of any other drug ■ Specific and superior in relief of SOMAtic pain ■ Modifies central perception of pain without abolishing natural defense reflexes ■ Relaxes abnormal tension of skeletal muscle

SOMA™

N-isopropyl-2-methyl-2-propyl-1, 3-propanediol dicarbamate

■ More specific than salicylates ■ Less drastic than steroids

■ More effective than muscle relaxants

SOMA has an unique analgesic action. It apparently modifies central pain perception without abolishing peripheral pain reflexes. SOMA is particularly effective in relieving joint pain. Patients say that they feel better and sleep better with SOMA than with previously used analgesic, sedative or relaxant drugs.
SOMA also relaxes muscle hypertonia, with its stresses on related joints, ligaments and skeletal structures.

ACTS FAST. Pain-relieving and relaxant effects start in 30 minutes and last 6 hours.

NOTABLY SAFE. Toxicity of SOMA is extremely low. No effects on liver, endocrine system, blood pressure, blood picture or urine have been reported. Some patients may become sleepy, particularly on high dosage.

EASY TO USE. Usual adult dose is one 350 mg. tablet 3 times daily and at bedtime.

SUPPLIED: Bottles of 50 white coated 350 mg. tablets.

Literature and samples on request.

WALLACE LABORATORIES, NEW BRUNSWICK, N. J.

THOMAS GRATZEK

(Continued from Page 1672)

he was one of the founders of the St. Paul Polish-American Club.

He was a former Ramsey County Deputy Coroner.

Doctor Gratzek is survived by his widow, Thesesa A.; two daughters, Mrs. Lee Kunz, New Ulm and Mrs. Robert Emmons, St. Paul; a son, Dr. John B., Madison, Wisconsin; two brothers, John, Strandquist, Minnesota, and Dr. Frank, Anoka; four sisters, Mrs. Pearl Yutrzenka, Mrs. Amelia Przybylski, both of Argyle, Minnesota, Mrs. Andrew Riminski, Strandquist, Minnesota, and Mrs. Wanda Kuznia, Stephen, Minnesota, and ten grandchildren.

HOWARD R. HARTMAN

Dr. Howard R. Hartman, a former member of the permanent staff of the Mayo Clinic and Head of a section in the Division of Medicine, died October 6, 1959. He was seventy-one years of age at the time of his death.

He was born December 1, 1887, at Toledo, Ohio. He received the degree of Bachelor of Science in 1911 and that of Doctor of Medicine in 1914 from the University of Michigan.

Doctor Hartman came to Rochester after graduation where he served his internship at St. Mary's Hospital until June 30, 1915.

Doctor Hartman was on leave of absence from October 1, 1917, to March 31, 1918. On August 1, 1919, he was appointed a first assistant in medicine in the Mayo Foundation, and on October 1 of that year he was appointed to the permanent staff of the Mayo Clinic as an Associate in Medicine.

Doctor Hartman, for many years, was physician to virtually all the Spanish speaking patients coming to the Mayo Clinic.

In 1938 he served as president of the Section of Medicine of the Pan-American Medical Association, which held a seventeen-day meeting in the form of a cruise to Cuba and the West Indies during the course of which various tropical diseases were studied intensively.

In 1944, the President of the Republic of Colombia conferred on Doctor Hartman, the title of Officer of the Order of Boyaca of that country, and in 1940 he was decorated with the Order of El Sol de Peru.

He was a Fellow of the American College of Physicians and a member of the Zumbro Valley Medical Society, the Minnesota State Medical Association, the American Medical Association, American Gastroenterological Association, American Society of Tropical Medicine, International Society of Gastroenterology, Pan-American Medical Association, Alumni Association of the Mayo Foundation, Society of Sigma Xi, Nu Sigma Nu professional medical fraternity, and the Alpha Omega Alpha medical honor society.

Also he was an honorary member of the Academia Nacionale de Medicina of Rio de Janeiro, Brazil; the Sociedad Medico-Cirurgico del Guayaquil, Equador; Academia Nacionale de Medicine of Lima, Peru, and the Associacion Medico del Peru and the World Medical Association.

ROGER H. HASSETT

Dr. Roger H. Hassett, a former Mankato physician and surgeon for thirty years, died August 23, 1959, at his home at 603 Canyon Place, Salona Beach, California. He was sixty-two years of age at the time of his death.

Doctor Hassett was born on June 27, 1896, at Storm Lake, Iowa, and attended school in Currie and Westbrook, Minnesota, and the College of St. Thomas, the University of Minnesota, University of Illinois and the Chicago Institute of Surgery. He started practice in Mankato in 1921.

He was a member of the Knights of Columbus, the Kiwanis Club, the Elks Lodge, American Legion, 40 and 8, the Blue Earth County Medical Society, the Minnesota State Medical Association and American Medical Association.

Doctor Hassett was associated with Dr. H. J. Lloyd from 1932 to 1938 and with Dr. L. G. Samuelson from 1938 to 1942. He established the Medical Center in 1942.

Surviving are: his wife, Marie; two sons, Dr. Gerald Hassett of Encino, California; Roger John of Milwaukee; two daughters, Mrs. Mike Seisel (Patty) of Santa Clara, California, Mrs. Charles Hathaway (Marie) of San Leandro, California; eight grandchildren.

ALEXANDER JOSEWICH

Dr. Alexander Josewich, former Head of the Tuberculosis Section of Veterans Hospital of Minneapolis, died September 19, 1959, at the age of sixty-nine.

A native of Milwaukee, Wisconsin, Dr. Josewich came to Minneapolis when he was two years old. He earned his undergraduate and medical degrees from the University of Minnesota. He was the first physician in Minnesota called to do tuberculosis work in the Army in World War I. He spent thirty-seven years in Federal Medical Service before retiring in 1954.

Doctor Josewich helped organize the Theodor Petersen American Legion Post No. 1 and was a member of Adath Jeshurun Synagogue, Temple Israel, the Jewish War Veterans, Trudeau Medical Society, the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors include his wife, May; three daughters, Lois and Betty, both of Minneapolis, and Mrs. Seymour Ohsman, Cedar Rapids, Iowa; and two sisters, Georgia, Minneapolis and Florence, St. Paul.

* * *

CLYDE ALBERT UNDINE

Dr. Clyde A. Undine, Minneapolis physician for forty-two years, died August 20, 1959. Doctor Undine was seventy-three years old.

A native of Minneapolis, Doctor Undine graduated from the University of Minnesota and attended medical schools at the University of Nebraska and Tulane University. He was on the staff of Deaconess Hospital and during World War I, served as a Lieutenant Commander in the Navy Medical Corps.

Doctor Undine was a member of the Internists Society, the Hennepin County Medical Society, the Minnesota State Medical Association, the American Medical Association, the American College of Physicians, Diabetic Association, Phi Rho Sigma medical fraternity, Minneapolis Lions Club and St. Mark's Church.

Surviving are his wife, Effie; a daughter, Mrs. Bryant Halsey, Morristown, N. J., and a son, Clyde, Jr., Minneapolis.

* * *

The Head of a section of surgery in the Mayo Clinic, **Dr. William H. ReMine,** has been elected to the Society of Head and Neck Surgeons. **Dr. Arnold J. Kremen,** Minneapolis is president of the organization.

* * *

Doctor and Mrs. **Warner Ogden,** St. Paul, have left for a visit of six months in Ghana, West Africa, where Doctor Ogden has an assignment in surgery in one of the new hospitals built by the local government. Doctor Ogden went on a similar expedition to India two years ago.

* * *

The Falls Clinic of Thief River Falls has announced the appointment of **Dr. Erick Reeber** to the staff. Doctor Reeber comes from New York.

* * *

A member of the Olmsted Medical Group, Dr. **Malcolm K. Campbell** recently attended a three-day symposium of Diseases Common to Animals and Man at the State University of Iowa. The meeting was sponsored by the Institute of Agricultural Medicine of the University.

* * *

The LeSueur Hospital Board recently approved the appointment of **Dr. P. J. Hiniker** as Acting Chief of Staff for the hospital. Doctor Hiniker will retain this position until a formed medical staff has been organized.

* * *

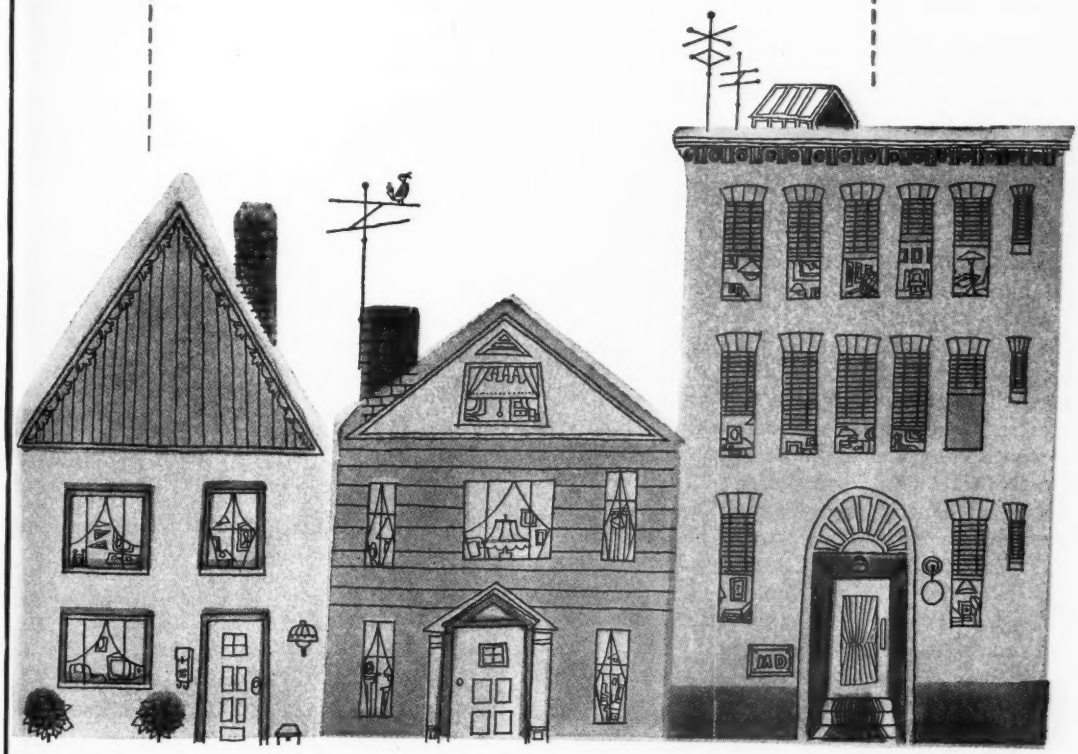
The Thirty-fifth annual reunion and meeting of the Alumni Association of the Mayo Foundation was conducted in Rochester recently. **Dr. George A. Lord** of Hanover, N. H., presided at the meeting. He was a fellow in surgery from 1935-38. Other officers are **Doctors L. Raymond Scherer,** Minneapolis; and **Howard A. Anderson,** Rochester. **Dr. Donald C. Balfour** is honorary president. General chairman of this year's reunion was **Dr. G. A. Peters;** Program Chairman was **Dr. C. A. Owen, Jr.,** and **Dr. H. J. Svien** was chairman of the Committee on Local Arrangements.

* * *

Dr. C. E. Thiem, Mankato, addressed the Medical Record Librarians of districts four and six at their regional meeting in Mankato recently. "Coding of Cardiac Diagnosis" was the topic of Doctor Thiem's talk.

* * *

Doctors of eight counties in the original Southwestern Minnesota sanatorium district payed tribute to **Dr. Sidney A. Slater,** Worthington, at the regional conference



(Continued on Page 1680)

"But, Doctor, I just can't swallow a lot of tablets"

"Little mother, just **ONE**

BONADOXIN®

tablet stops morning sickness (you take it at bedtime)"

The formula tells why BONADOXIN quickly stops nausea and vomiting of pregnancy in 9 out of 10 cases.* Each tiny BONADOXIN tablet contains: Meclizine HCl (25 mg.) for antinauseant action / Pyridoxine HCl (50 mg.) for metabolic replacement

More than 60,000,000 tablets prescribed and taken. Toxicity low, tolerance excellent. In bottles of 25 and 100. Usual dose: one tablet at bedtime; severe cases may require another on arising. See PDR, p. 779.

BONADOXIN also effectively relieves nausea and vomiting associated with: anesthesia, radiation sickness, Meniere's syndrome, labyrinthitis, cerebral arteriosclerosis and motion sickness.

After Baby Comes

For infant colic, try antispasmodic BONADOXIN Drops... stop colic in 7 out of 8 cases.*

Each cc. contains:
Meclizine 8.33 mg. / Pyridoxine 16.67 mg.

See PDR, p. 779.

For fast, complete treatment of vaginal infections

Problem is: she'll wait until discomfort is acute and then expect immediate relief. The answer is Trisert. Trisert preparations contain ALLANTOIN, an effective debriding agent which quickly dissolves heavy mucus often accompanying vaginal infections . . . METHYLBENZETHONIUM CHLORIDE, a quaternary germicide which removes unpleasant odors . . . SUCCINIC ACID, an aid in maintaining optimal vaginal pH . . . 9-AMINOACRIDINE HYDROCHLORIDE which has been included to supplement the bactericidal and trichomonacidal activity of other constituents. Treatment with Trisert Powder will control symptoms fast . . . usually within an hour . . . and provide effective initial treatment for 48 hours. After a second insufflation, the treatment is completed with at home use of Trisert Tablets which will generally bring the infection under complete control within 7 days.

Trisert

TRISERT TABLETS—Patient set, contains bottle of 30 tablets and special inserter. Bulk bottle of 100 tablets.

TRISERT POWDER—Available in 4 gr. individual treatment bottles. 12 to carton.

TRISERT POWDER INSUFFLATOR—Designed for use with Trisert Powder. Its use is urged for maximum efficiency.

on tuberculosis in Worthington. The doctors, all lifelong friends of Doctor Slater were **Doctors C. L. Sherman,** Luverne, representing Rock County; **W. G. Benjamin,** Pipestone, representing Pipestone County; **R. F. Pierson,** Slayton, Murray County; **Walter H. Halloran,** Jackson, Jackson County; **J. H. Dokken,** Windom, Cottonwood County; **W. H. Valentine,** Tracy, Lyon County; **A. L. Vadheim,** Tyler, Lincoln County; and **E. A. Kilbride,** Worthington, Nobles County.

* * *

The Fall Meeting of the Red River Valley Medical Society was held recently in Crookston. **Dr. John Gordon,** University of Minnesota, discussed problems in anesthesia.

* * *

Dr. Kenath H. Sponsel, Minneapolis, recently was a guest speaker at the Aberdeen, South Dakota, District Medical Society meeting. "Hip Fracture" was the subject presented by Doctor Sponsel.

* * *

The Minnesota community of Clarissa recently honored **Doctor** and Mrs. **F. N. Grose** on their silver wedding anniversary. The community held an Open House for the couple.

* * *

Luverne physicians, **Doctors E. S. Boone** and **A. C. Martin,** recently announced that their offices have been moved to a new building at 413 West Main in Luverne. The doctors will maintain individual offices and separate practices but will share a reception room and x-ray facilities.

* * *

The promotion of **Dr. William C. Bernstein,** St. Paul, to Clinical Professor of Surgery was recently announced.

* * *

Dr. Ralph Papermaster, Two Harbors, has recently been elected president and chief of staff at the annual meeting of the medical staff of the Lake View Memorial Hospital. Also elected to medical staff positions were **Dr. Harold Leppink,** vice president and **Doctor Gerald Church,** secretary-treasurer.

* * *

International Falls physician, **Dr. R. D. Hanover,** has given the village of Big Falls his former office building located in that village. The property consists of four lots and a modern house.

* * *

Guest speaker at the McLeod County Public Health Association annual dinner meeting was **Dr. E. M. Litin,** Rochester. Doctor Litin's topic was mental health.

* * *

The community of Cannon Falls recently announced the completion of the **Dr. M. R. Williams'** Medical Arts Building. The doctor and his staff have moved into the building.

Over seven hundred friends from the Fulda area recently honored **Doctor** and Mrs. **B. M. Stevenson** at Memorial Hall, Fulda. The friends gathered to bid a farewell to the Stevensons who left recently for Oregon.

* * *

The Surgical and Medical Clinic of Albert Lea announced the recent appointment of **Dr. Jack T. Berry** to the staff.

* * *

Dr. W. H. Parker and **Dr. K. J. Halverson** of the Mesaba Clinic, recently announced the appointments of **Doctors E. P. Bryant** and **L. M. Flannary** to be associated with them in the practice of medicine.

* * *

The community of Ellendale recently announced that **Doctor Myron Doebler** has accepted a practice of medicine in that community. Doctor Doebler has been practicing in Pine River where he has been associated with **Doctor Charles Pelzl** of that community.

* * *

The Minneapolis Board of Public Welfare recently filled two key posts in the medical staff of General Hospital. **Dr. Fred W. Hoffbauer** was named Chief of Medical Services and **Dr. William Jepson** was named Chief of Psychiatry. **Dr. Thomas Lowry** is the hospital's medical director.

* * *

Ten Minnesota surgeons were among the approximately 1,015 surgeons who were inducted recently as new Fellows of the American College of Surgeons in cap-and-gown ceremonies closing the annual five-day Clinical Congress of the world's largest organization of surgeons. Those receiving this distinction from Minnesota at the 1959 Convocation are as follows: **Dr. George N. Kraemer,** Fairmont; **Dr. Calvin J. Johnson,** Grand Rapids; **Dr. Martin A. Nordland,** Minneapolis; **Doctors John C. Campbell, James K. Masson,** and **Charles R. Sullivan,** Rochester; **Doctors Jerome A. Hilger** and **Lloyd D. MacLean,** St. Paul; and **Dr. Oskar P. Friedlieb** of Virginia.

* * *

Dr. Louis A. Buie, Mayo Clinic and a member of the staff until 1955, was made an honorary member of the Royal Society of Medicine of England on July 1, according to information received from London. The certificate of honorary members, signed by **Dr. Henry R. Thompson,** president of the society, indicates that the honor was conferred upon Doctor Buie "for distinguished services to science."

* * *

Replacing **Dr. Reynold A. Jensen,** Professor of Child Psychiatry at the University of Minnesota, while he is on sabbatical leave will be **Dr. Leo Kanner,** Professor of Child Psychiatry at Johns Hopkins Hospital, Baltimore, Maryland. Doctor Jensen will study child psychiatry techniques, facilities, and research programs in Europe while on leave during academic years 1959-60.

* * *

Dr. A. C. Kerkhof, president of the Minnesota Heart Association announced that the association will support heart research with an additional $35,000 raised by the independent Heart fund this year.

Minnesota physicians attending the thirty-fifth annual meeting of the American Heart Association recently in Philadelphia were: **Dr. A. C. Kerkhof,** president of the Minnesota Heart Association and **Dr. Karl W. Anderson,** immediate past president.

* * *

An Ely Clinic staff member, **Dr. M. G. Dobler,** has recently returned from several weeks' stay in Europe. While there, he did three weeks' postgraduate study at the International Congress of Surgery in Munich, Germany. He was also guest physician at the University of Zurich, Switzerland, and the University of Tübingen, Germany.

* * *

Dr. Randall G. Sprague, Mayo Clinic, recently was honored as one of Northwestern University medical school's distinguished alumni during ceremonies marking the school's 100th anniversary.

* * *

Olmsted Medical Group staff member, **Dr. John R. Watson,** recently announced that he will move to Medford, Oregon, where he will enter the private practice of obstetrics and gynecology.

* * *

Dr. Arthur H. Wells, Duluth, has been elected to the Board of Directors of the American Medical Writers Association. Doctor Wells is Editor-in-Chief of MINNESOTA MEDICINE.

* * *

The twenty-third annual Montana-Wyoming regional meeting of the American College of Physicians held in Billings, Montana, recently had as banquet speaker, **Dr. Wesley W. Spink,** Minneapolis. Dr. Spink spoke on "The Education of a Doctor."

* * *

A group of former associates of **Dr. John S. Lundy,** Mayo Clinic, recently honored Doctor Lundy on his retirement. Doctor Lundy is a founder of the Mayo Clinic's Section of Anesthesiology.

* * *

St. Paul physician, **Dr. John F. Briggs,** and University of Minnesota physician, **Dr. J. Arthur Myers,** recently spoke on diseases of the heart and lungs at a convention of the American College of Chest Physicians.

* * *

Dr. A. B. Sundberg, Heron Lake, was recently named medical consultant to the Jackson County Tuberculosis and Health Association. Doctor Sundberg succeeds the late **Dr. S. A. Slater** of Worthington.

* * *

Delegates at the forty-fifth annual clinical congress of the American College of Surgeons in Atlantic City heard **Dr. William B. Stromme,** Minneapolis, present a paper on "Intra-uterine Fetal Deaths in the Second Trimester."

* * *

Doctors from the Mayo Clinic who served on the committee to select awards given during the thirty-fifth annual meeting of the Alumni Association of the Mayo Foundation were **Dr. James W. Kernohan** and **Dr. C. F. Gastineau.**

The Diarrhea of American Travelers Abroad

Presented at the clinical meeting of the American Medical Association, Minneapolis, Minnesota, December 4, 1958.

B. H. KEAN, M.D.
New York, New York

Dr. Kean is Associate Professor of Clinical Medicine (Tropical Medicine), Cornell University Medical College, New York City.

DURING the past several years my colleagues, Dr. Wilson G. Smillie, Dr. Gerardo Varela, Somerset R. Waters, Dr. Harold A. Tucker, others and I have conducted a series of small studies, each designed to answer a few specific questions about the diarrhea of travelers. The initial studies were conducted among 800 U. S. students traveling to Europe. From these investigations it was determined that the diarrhea of travelers, at least of travelers to Europe, was not due to amebae, to *Trichomonas hominis,* to *Giardia lamblia,* or to any known parasite. In addition, it was established that the incidence of diarrhea was approximately twice as high among those who went to southern Europe and to the Mediterranean area than in those who visited the northern part of Europe, especially Scandinavia. For several reasons, which included the cooperation of the authorities and the availability of a large number of students, the investigations were transferred to Mexico. I would like to report to you briefly on the results of three of our studies there.

Using epidemiologic methods, we interviewed, at the Los Angeles Airport, approximately 1200 U. S. tourists returning to the United States from a vacation trip to Mexico. Half were males and half were females. Thirty-three per cent became ill the first week, and over 90 per cent became ill within the first fortnight of their trip to Mexico. In most, the duration of the illness was brief—one day, but at least half were sick two to four days. Most suffered only one attack, but one-half were sick two or more times. The illness, on the whole, was mild but approximately half of the tourists to Mexico were sick enough to be confined to quarters at least part of their vacation.

A rather unexpected observation was the fact that the incidence of diarrhea appeared to be considerably higher in the younger than in the older. In the student age group (twenty-four years

of age and under) 43 per cent were ill, whereas of the senior citizens (over fifty-five years) only 18 per cent became ill. Whether this represents a reflection of the habits of the travelers or has basic immunologic foundation, is not known.

There has been a lot of speculation as to whether psychologic factors, liquor, and the excitement of travel could be responsible for travelers' diarrhea. To evaluate this aspect of the problem, we interviewed 200 tourists who had just returned from a vacation in Hawaii instead of Mexico. Only 7 per cent reported the development of diarrhea during their visit to Hawaii in contrast to the 33 per cent who became ill in Mexico.

Following these elementary epidemiologic studies, a different type of project was designed in hope of answering the following question: are any of the known, common, enteropathogenic bacteria responsible for the diarrhea of tourists? We arbitrarily defined pathogenic bacteria of the intestinal tract as the following: Salmonella sp., Shigella sp., Klebsiella sp., Paracolobactrum sp., Proteus sp., and twelve different serologic subspecies of *Escherichia coli.* Sixty-two recently-arrived U. S. students studying in Mexico summer school (1958) were asked to provide a stool specimen every day for fourteen consecutive days before, during, and after their illness to ensure the culturing of pathogenic bacteria which might be present in the stool only briefly. It was anticipated that approximately 35 to 40 per cent of the students would become ill. Actually, of the sixty-two, thirty-five remained well and twenty-seven did become ill.

Of the thirty-five well students, twelve had Paracolobactrum sp. scattered rather indiscriminately during the fourteen-day study period, five had Klebsiella sp., and two had pathogenic *E. coli.* Of the twenty-seven sick, fifteen had Paracolobactrum sp., eight had Klebsiella sp., and nine had pathogenic *E. coli.* In none of the sixty-two was Shigella sp. cultured, and in none of the sixty-two was Salmonella sp. cultured. Our conclusions were as follows: first, that neither Shigella nor Salmonella were responsible for tourists' diarrhea; and second, that the scatter and the distribution of the other arbitrarily-designated pathogens was such, that to assign an etiologic role to any of these organisms would be extremely hazardous. In fact, our impression was that the "pathogens" appeared in the same fashion that secondary invaders appear in respiratory tract infections of viral origin. In studies to be conducted in 1959-1960, an effort will be made to incriminate some of the enteropathogenic viruses and to assess the role of staphylococci.

We can now turn to a study in prophylaxis with drugs. In our first epidemiologic study involving a questionnaire of 1265 tourists, 444 indicated that they had used some medication. Of these, more than half contracted diarrhea. The most popular drug was halogenated quinoline iodochlorhydroxyquin marketed under the name of Entero-Vioform. Many of our colleagues have used this preparation with a great deal of enthusiasm.

In our experiment, approximately 600 American students in two schools in Mexico City were asked to take a drug twice a day for fourteen days from the day they arrived in Mexico. This was not actually accomplished—most did not start taking the drug until three days had elapsed. The students "checked in" every day at our health center and if they became ill with diarrhea, the drugs were stopped and an investigation was made.

The three drugs which were tested were as follows: First, Entero-Vioform—it is the most popular and has been recommended by many authorities. The dose was 375 mg. twice a day. The second drug was neomycin. The dose was 375 mg. twice a day—not a large dose, but since we were dealing with unprotected students it was best to be conservative. Small amounts of kaolin and pectin were included in this preparation, which was unfortunate, although the neomycin was the only drug present in effective doses. The third drug was a lactose placebo. All preparations were packaged in exactly the same fashion, with the same size, same taste, and same color; those administering the drugs did not know which drug they were using.

Iodochlorhydroxyquin, Entero-Vioform, proved ineffective. Of those taking the drug, 38 per cent became ill. Of those taking the placebo, 33 per cent became ill. Neomycin scored somewhat better —only 20 per cent became ill.

A more dramatic set of figures was derived by segregating approximately 150 students who began taking the drug on the day of arrival. Of this 150 students, exactly 35 per cent became ill when they took the placebo, 35 per cent became ill when they took Entero-Vioform, 16 per cent became ill when they took the neomycin.

Our conclusion from this study was that Entero-Vioform was no more effective than a placebo and that neomycin had some suggestion of effectiveness.

We are not prepared to advocate the use of any preparation for the prophylaxis of tourist diarrhea. Future studies and the direction they should take must be reasonably obvious to this group. Since 1,500,000 U. S. students travel abroad each year and since this number will likely increase in the next decade, the magnitude of the problem can hardly be exaggerated.

Questions Asked of Dr. Kean at the End of His Presentation

Question: Is there any relationship between this diarrhea and the consumption of liquor by travelers?

Answer: There is no major relationship to drinking. We had no reason to believe that drinking of American tourists in Hawaii was less than in Mexico, although we do admit that the caliber of the drinking may have been different. However, more important, the incidence of diarrhea was twice, almost three times as high in students who went to southern Europe than in those who went to northern Europe. We think the quantity of alcohol consumed was probably the same but it is true that the combinations of liquor might have been different.

Question: Although this is outside the scope of your present studies, Dr. Kean, how do you feel about drinking water?

Answer: We feel that from the day one leaves the continental United States, with the exception possibly of Canada, Hawaii, and England, that the drinking of tap water should be "verboten." Drinking tap water in France, Italy, and most of the other countries which esthetically would be considered civilized, in my opinion, is dangerous.

Question: What about fresh vegetables?

Answer: Fresh vegetables are dangerous even when consumed in New Jersey. Nevertheless we again must make a geographic limitation. We do not think there is any effective way of cleaning or sterilizing fresh vegetables. Potassium permanganate or chlorine, acetic acid, and other preparations are not effective. A blow torch might clean up lettuce in Mexico or in southern Europe. There is very little chance of Americans developing vitamin deficiency during a trip abroad. I have the rather parochial feeling that when we leave the areas where we feel comfortable and safe, that fresh vegetables had better not be consumed. This is especially true for those who are taking a brief trip and to whom two or three days' illness represents a major hazard. If you have any particular countries in mind we might modify this. I suspect lettuce in Scandinavia is safe but most of us go to more exotic parts of the world and there the answer is: "no."

Question: Once it develops, is there any effective treatment of travelers' diarrhea?

Answer: Once the diarrhea develops it follows such a systematic course that almost any treatment that is used will get credit for cure. It is on this basis that so many of the drugs have been popular for so long. Nevertheless there are certain principles of treatment of travelers' diarrhea which should be mentioned. First, it seems perfectly reasonable to advocate that we eat rather than starve. A wonderful, nutritious diet available abroad in almost any part of the world is tea, rice, and applesauce—tea for the liquid, rice for a sense of nutrition, and applesauce because it is comforting and possibly because it contains tannins. A useful drug is paregoric. If fever is present one of the antibiotics—a sulfonamide or tetracycline could be used—but only a very small percentage of these patients is sick enough even to raise the problem of antibiotics. Tea, rice, applesauce, and a little paregoric for twenty-four to forty-eight hours, will usually keep the patient comfortable for the twenty-four to forty-eight hours of illness.

Question: Since paregoric is an opiate derivative, won't some difficulty be encountered in taking it from country to country?

Answer: That is a most important point and I am glad you raised it. It is against the law for a patient or a doctor to take paregoric—even one ounce of paregoric—outside the United States or across any international borders. It would be unwise to recommend to any public group that paregoric be taken abroad. However, in those countries where the narcotic problem is the greatest, there it is most difficult to obtain a reasonable amount of paregoric. If you were to prescribe a small amount, for example 120 cc. of paregoric to a patient on general principles and that patient were to take that paregoric abroad, it is unlikely that any question would be raised by the authorities. But once again, it would be extremely unwise to make such a recommendation to any public group.

Experiences with the Billroth I Gastric

● *Despite the speed with which many medical and surgical techniques become old-fashioned, "ancient" procedures may continue to be valuable. Such is true of the Billroth I method for gastrectomy. Since its birth in 1881, it has gone through several cycles of wide application and neglect. This article emphasizes its current application and the excellent results it produces in properly selected cases.*

THE BILLROTH I operation has been discussed considerably in the last several years. This is an old operation, actually representing the method employed by Billroth in his first successful gastrectomy, and it became rather routine in many surgical centers in which resection was employed largely for gastric lesions (before duodenal ulcer was treated by removal of part of the stomach). When European surgeons focused great attention on gastric resection for duodenal ulcer and when variations of the Polya operation became commonplace, the Billroth I procedure was neglected in many places. During and immediately after World War II, a great reawakening of interest in the Billroth I method was evident, and a large series of patients so treated is now available for significant review.

Several variations have occurred in the Billroth I concept. Billroth himself did largely an antrectomy in his first operation, in 1881. He narrowed the aperture of the stomach by closing a bit of the lesser curvature before accomplishing end-to-end gastroduodenostomy. Two years later, Kocher publicized his method of closing the gastric aperture completely and anastomosing the duodenum to the posterior wall of the stomach just proximal to this point of closure. In 1911, Schoemaker made a significant contribution, pointing out that all or most of the lesser curvature of the stomach might be removed and that, by closing this aspect at a sharp angle, one created a tubelike structure from the remnant of the greater curvature, allowing retention of a good portion of functioning stomach; a satisfactory end-to-end gastroduodenostomy was the final step. Von Haberer, in 1922, followed by Finney 1 year later, made known the still useful method in which the stump of the duodenum is closed and, after complete mobilization, the side of the duodenum is anastomosed with the cut end of the stomach. Horsley, in 1926, merely reversed the Schoemaker principle by closing a portion of the greater curvature and placing the anastomosis toward the lesser curvature. Finally, in 1933, Von Haberer described a method (that must have occurred to many surgeons long before) in which the pouch of the gastric remnant simply was puckered down to meet the stoma of the duodenum in a complete end-to-end fashion.

My own interest in the Billroth I type of operation developed in 1947, when it was demonstrated that, in the very occasional total gastrectomy, reconstruction might be accomplished by end-to-end esophagoduodenostomy. This was true large-

Billroth Resection

EDWARD S. JUDD, M.D.
Rochester, Minnesota

Read at the meeting of the Minneapolis Surgical Society, Minneapolis, Minnesota, May 7, 1959.

From the Section of Surgery, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

ly in patients who had lost a good deal of weight and who had a certain amount of visceroptosis. In addition, tension could be removed from the anastomosis by complete "Kocherization" of the duodenum, followed by suture of the duodenum to the anterior surface of the pancreas to eliminate all dragging and pulling on it. The advantages of this method appeared obvious, and I have continued to employ it in isolated instances. The fact that total gastrectomy may be done in this manner certainly answers critics of the Billroth I operation, who consider that it is impossible to resect a sufficient amount of stomach and still employ an end-to-end anastomosis.

Technical Observations

A decision concerning the type of reconstruction is not made until the extent of the resection has been thoroughly mapped out and the commitment is clear. If it then appears that any degree of tension will be present, the duodenal stump is inverted in the usual manner and some form of a Billroth II operation is used. One may remove the entire lesser curvature readily, if he wishes, and may close over this aspect of the stomach by employing the Furness clamp and pin (Schoemaker method). The use of matching anastomotic clamps makes it easy to assess the exact amount of greater curvature to be encompassed for purposes of anastomosis, as the duodenum already has been measured in its matching clamp when it is severed. I am still old-fashioned enough to want two complete rows of suture to close the Schoemaker aspect of the repair, and I frequently buttress this with a final layer.

I have preferred the open method of anastomosis for some time, as the surgeon can tell more accurately just where each stitch is going and he is less likely to invert too large a "cuff," resulting in obstruction. Also, the incidence of hemorrhage at the suture line is more readily minimized, as the suture line may be inspected by removing the clamp momentarily and securing any bleeding points by direct suture before the final rows are placed. Special attention must be paid to the "fatal angle of Billroth," which is at the bottom end of the Schoemaker reconstruction of the lesser curvature where the upper margin of duodenum is joined to the anastomosis. It is extremely important to place a deep mattress suture of silk, which passes first through the anterior gastric wall and then into the posterior gastric wall, continuing across the upper aspect of the duodenum and finally back to the anterior

gastric wall. When this suture is snugged up, it results practically in a purse string, with effective closure of this previously troublesome angle.

Conditions in Which the Operation Is Used

Peptic ulcer is the primary indication for this operation, which continues to have wide acceptance at the Mayo Clinic in the treatment of gastric ulcer. It is a temptation to employ it also for duodenal ulcer, but the duodenal ulcer that demands surgical treatment often has distorted the duodenal wall so greatly that one would scarcely consider use of the Billroth I procedure. However, my colleagues and I do use it in certain instances. Some authorities consider that carcinoma of the stomach is an absolute contraindication to use of the Billroth I technic. However, we have not hesitated to use it if the carcinoma is well away from the duodenum and if complete and radical subtotal gastrectomy is possible without any compromise. In the cases of severe chronic gastritis that occasionally confront the surgeon who is operating as the result of a mistaken diagnosis and who is reluctant to do only gastrotomy and biopsy, especially when hemorrhage is a part of the history, this operation has proved useful. It is a temptation to employ this procedure rather frequently for gastrojejunal ulcer in which extensive resection of the jejunum, with repair and prolonged and difficult manipulation, is required to carry out a proper high gastric resection. We have yielded to the temptation on occasion, although we have attempted to individualize the cases. The method has a certain appeal in the treatment of multiple polyposis of the stomach, as it minimizes surgical intervention. The operation is also useful in other and less common situations.

Duodenal Ulcer and the Billroth I Resection

My senior colleague, Dr. Waltman Walters, frequently has pointed out that the rate of recurrent ulceration after use of the Billroth I method in treating duodenal ulcer is too high to allow its routine employment. He argues, with considerable weight of evidence, that the constant regurgitation of alkaline material into the stomach, which is an accompaniment of the Polya or the Billroth II method, is usually lacking after the Billroth I procedure. More often, we have not employed the operation, as already mentioned, because a badly distorted duodenum tends to discourage consideration of an anastomosis to be placed there. On such occasions, we are satisfied to obtain some type of closure of the stump that will not disrupt. Critics of this operation have said that the enthusiasts would be inclined to do too limited a resection because they are thinking ahead to the anastomosis and may remove a suboptimal amount of stomach. However, when one reflects on the occasional total gastrectomy done with an end-to-end anastomosis, this does not appear to be a valid argument. As indicated previously, we still do an occasional Billroth I operation for duodenal ulcer when the situation appears to be correct. This might include the elderly patient who would not withstand a prolonged operation or the patient with an acutely perforated ulcer in whom resection as an emergency procedure apparently is feasible.

Other Operations Concomitant With This Procedure

Since the Billroth I method represents the least amount of operative intervention in gastric resection, it is useful when other surgical procedures might be done at the same time. If a more prolonged and complex operation were done on the stomach, the surgeon might be tempted to leave the extirpation of other lesions for another day. Thus, splenectomy occasionally is done without undue regard to having imposed too much surgical risk. Cholecystectomy is not at all unusual as a secondary procedure. Appendectomy frequently is done without great concern. The "take down" of a previous gastroenteric stoma, with resection or repair of the jejunum and immediate resection of the stomach, often is done most advantageously in this way. Extensive ventral hernias have been repaired at the same time as the Billroth I operation. Partial hepatectomy, partial pancreatectomy, segmental colonic resection and numerous other operations have been conducted successfully at the same time.

Our Present Stand

At present, several surgeons at the Mayo Clinic are enthusiastic about the Billroth I method in the treatment of benign gastric ulcer because we think that we can remove exactly as much stomach as desirable and still re-establish continuity in the most simple and direct fashion.

Several of us are interested in hemigastrectomy plus vagotomy for those patients requiring gastric

resection for duodenal ulcer who, in an earlier year, would have been candidates for "gastric crippling" if an extremely high gastric resection were done. The procedure of combining vagotomy with removal of half of the stomach and completing the operation by a Billroth I method strikes an attractive compromise that bears further watching. We have a growing series of such patients who all suffered from complications of duodenal ulcer and who now are flourishing without the numerous side effects that might have been the rule otherwise. It is still too early to allow final conclusions, but present impressions lead us to continue the trial.

Carcinoma of the stomach, if it is not too close to the pylorus, can be well handled by this method. All of the omenta can be removed, along with the spleen, various groups of lymph nodes, and part of the pancreas, if desired, and reconstruction still can be accomplished by the end-to-end method; although this extensive procedure is not often feasible, it works out well on occasions. I recently examined a patient who had this operation six years ago, at which time several lymph nodes in the omentum were found to be metastatically involved. At present, the patient is in excellent health; roentgenologic studies reveal a small gastric remnant that functions efficiently, with no evidence of recurrence.

Gastrojejunal ulcer already has been mentioned as a possible indication for this operation. After the surgeon takes down the gastroenteric stoma, which may be a hazardous procedure if the transverse mesocolon is badly involved, completely mobilizes the ulcer, resects the jejunum and does an end-to-end anastomosis, he is still faced with a high gastric resection, which may impose a great deal of surgical trauma on a rather depleted patient. In such instances, it is a temptation to use the Billroth I method, and I have done it fairly frequently, apparently with good results. The combination of this operation with vagotomy gives at least theoretic protection against further recurrent ulceration.

Advantages of the Operation

Obviously, this is by far the simplest method to achieve the desired results. It is not necessary to attach the stomach to the intestine at some distance from the point where nature intended it to be attached. Only one suture line is present, which minimizes the constant worry of the surgeon in this regard.

The method is relatively safe. Recent study of a large series at the clinic shows a mortality rate of less than 2 per cent.

It is the most direct method that can be devised. The food enters the duodenum at almost the normal natural level, and it is mixed with bile, pancreatic juice and succus entericus exactly where nature intended it to be. It is our opinion that the immediate postoperative convalescence is definitely better for this reason. "Dumping" and similar unpleasant side effects occur less frequently than they do after other procedures. Analysis of feces in many of our patients demonstrates that the loss of fat and nitrogenous products in the stool after a Billroth I operation is consistently less than it is after a "full width" Polya procedure. Not only is the early convalescence usually much easier for the patient but the long-term situation appears to be better. Further evidence in this regard is forthcoming when one hears surgeons advising that those patients not doing well after the Billroth II operation for duodenal ulcer (because of the dumping syndrome) should have their reconstruction altered by the Billroth I method.

Finally, from the technical standpoint, the surgical dilemma is kept to a minimum. There is no duodenal stump to worry about, which is often the source of the extremely difficult and occasionally fatal complications that may arise with other methods. Also, there is no dilemma concerning the anterior versus the posterior position for the anastomosis, nor is the operation prolonged and made more difficult when such a decision has been made.

Conclusions

The Billroth I method for gastric resection is an old and time-honored operation. It had been neglected for several decades, but it has been revived of late. Under properly selected conditions, it is an excellent operation that continues to yield a high incidence of eminently satisfactory results.

A Review of Billroth I Gastrectomy

TABLE I. AUTHOR'S EXPERIENCE—BILLROTH I TYPE GASTRECTOMY

	Total Cases—20
Indications	
Gastric ulcer	12
Duodenal ulcer	7
Gastric polyp	1
Deaths	
Postoperative	1
Unrelated	1
Lost to follow-up	2
Recurrence	0
Present known good results	16
Dumping	1 (mild)

Inaugural thesis presented before the Minneapolis Surgical Society, May 7, 1959.

M. D. McCAMPBELL, M.D.
Minneapolis, Minnesota

IN RECENT YEARS, there has been a revival of interest in and use of the so-called Billroth I type subtotal gastric resection, or more correctly, subtotal gastrectomy with gastroduodenostomy. The first gastrectomy was performed by the Frenchman, Jules Emile Péan, on April 9, 1879. He re-established continuity by gastroduodenal anastomosis. The second one was performed on November 16, 1880 by Ludwig von Rydygier. Both of these patients died in the immediate postoperative period.

The third recorded gastric resection was performed by Theodore Billroth on January 29, 1881, for carcinoma of the stomach. The patient survived the operation but died four months later due to diffuse hepatic and omental metastasis. The first two such operations performed by Billroth were done with the anastomosis on the lesser curvature side. However, later, Billroth changed to the greater curvature side for his anastomosis because he felt it would minimize the chances of stomal obstruction, this complication having caused death in his second operation.

Soon after 1881, the gastroduodenal anastomosis fell into disfavor. Its decline would seem largely due to the difficulty in preventing leakage in an anastomosis between the large gastric stump and the smaller end of the duodenum. On January 15, 1885, Billroth performed a prototype of what is now known as the Billroth II gastric resection. This found favor with most of the surgeons of that day, and for a long time satisfaction with this procedure seems to have contributed to failure to refine and overcome the technical problem of the Billroth I procedure.

In the early 1900's, Schoemaker began to remove much larger amounts of the lesser curvature of the stomach in order to gain a wider margin beyond gastric carcinoma. His method equalized the gastric and duodenal stump so that anastomosis could be satisfactorily carried out. It is the modification of Schoemaker that is in wide use today, although other modifications of the Billroth I, particularly those of Finney and Horsley, have enjoyed favor by some surgeons. For a more complete discussion of the history of the gastric resection, the reader is referred to the excellent monograph by Moore and Harkins[1] published in 1954.

On consideration of what type of gastric operations should be performed when resection is indicated, for a variety of reasons, the following factors would seem to indicate that the Billroth I might well be favored:

1. It is the most physiologic in that it removes the antrum and vagal stimulation and re-establishes continuity.

2. The ulcer is removed.

3. It should give the best protection against future complications. Harkins states that because of Brunner's glands, the duodenum is better equipped to resist acid pepsin. Dragstedt[2] has suggested that the duodenum naturally possesses greater mucosal resistance than the jejunum. Connelly, et al,[3] state that gastric secretion studies after three-fourths gastrectomy almost always show either no free hydrochloric acid or greatly reduced HCl and that marginal ulceration does not occur if the gastric pH remains above 5.0.

4. There is no blind duodenal stump and no afferent limb to become obstructed or form jejunocolic fistula.

5. The technique of the Billroth I is easier and can be performed entirely in the supracolic compartment of the abdomen.

6. It is faster because it reduces the time consumed in closing the duodenum and opening the jejunum as required in the Billroth II.

7. The nutritional status is better. Ellison, Cole and others[4] have shown that less nitrogen and fat is excreted in the stool after the Billroth I procedure than after the Billroth II. Wollaeger[5] has shown that a better weight gain occurs.

The presence of kyme in the duodenum gives maximal stimulation of secretion leading to bile and pancreatic secretion and thus along with the normal continuity promotes a better mixing of the digestive elements with food.

Lundh,[6] in a series of studies reported in Stockholm in 1958, stated that the superiority of the Billroth I anastomosis over the Billroth II anastomosis in nutritional respects seemed clearly shown from his studies and that in the Billroth I group are found the more favorable conditions for digestion and absorption in that part of the intestine where absorption and digestion normally take place.

8. There is slower emptying of the gastric remnant which results in less dumping syndrome.

Description of Procedure.—Since 1956, we have been performing subtotal gastrectomy with gastroduodenostomy wherever possible for a variety of indications and, in fact, in all cases which meet the following two requirements: (1) that the ulcer can safely be excised, and (2) that after seventy-five per cent resection of the stomach, anastomosis can be carried out without tension at the suture lines.

The procedure has been essentially the Schoemaker modification of the Billroth I resection carried out as follows: A left subcostal incision extending approximately two inches to the right of the midline is used. The stomach is delivered and the omentum divided from the peritoneal reflection on the duodenum to and including the most distal one or two vasa brevia except in cases of large gastric ulcers or obvious or suspected gastric carcinoma in which case the entire omentum is removed. The right gastric artery is divided, the lesser omentum entered and the duodenum freed up to a point beyond the ulcer which is possible in most cases but may necessitate mobilization of the second part of the duodenum by incision of the lateral peritoneal reflection. The duodenum then is transected and a clamp is left on the duodenum. Next, approximately 75 per cent resection is carried out, placing a clamp on the lesser curvature side at the level of the most distal vas brevis at a right angle to the curvature for a distance of 5 cm. Another clamp is then angled up to within 1 inch of the esophagastric junction and the distal stomach thus excised. The lesser curvature side of the cut end is then closed in two layers, using a running over-and-over hemastatic suture of No. 0 chromic followed by inversion with Lembert sutures of silk. Then, if the remaining 5 cm. open end of the stomach can be easily approximated to the cut end of the duodenum without tension, and indeed they usually overlap, an open two-layer anastomosis is carried out. In all cases, the left gastric artery is divided near its origin.

Gastric suction is utilized for the first twenty-four to forty-eight hours and the tube then removed. The patient starts first on clear liquids and gradually progresses to five or six small soft feedings daily by the fourth or fifth postoperative day. In contrast to the various modifications of the Billroth II procedure, we have had no cases in which gastric suction was necessary beyond seventy-two hours. During the time of suction, fluid and electrolytes are carefully watched and replaced as indicated.

My cases are few in number, but at least they serve as encouragement in greater use of this procedure. I performed twenty Billroth I gastric resections as described above since the latter half of 1953 with follow-ups varying from five years to six months. There were two deaths, one at fourteen days postoperative, due to myocardial infarction, in a man seventy-eight years of age who had

an otherwise uneventful postoperative course. Another death occurred at eighteen months of entirely unrelated circumstances and at the time of death the patient's nutritional course was good

per cent recurrence rate after resection for gastric ulcer and 9 per cent for resection for duodenal ulcer. Connelly, Lempka, et al,[3] in a series of 133 cases, report a 1.5 per cent mortality with no re-

TABLE II

	Total Patients	Gastric Ulcer	Duodenal Ulcer	Other—Incl. Mixed	Percent Dumping Incl. Mild	Mortality	Percent Excellent and Good Results	Recurrence

with no complaints referable to the gastrointestinal tract. Two patients, who were lost to follow-up after slightly more than one year, were free of complaints and rated as excellent results at that time (Table I).

The indications for surgery in these cases were: gastric ulcer (12), gastric polyp (1), duodenal ulcer (7). Of the sixteen cases followed, thirteen have maintained or exceeded their preoperative normal weight and the remaining three have lost less than ten per cent of their preoperative normal weight. There are no proven or suspected recurrences at the present time. One patient, one year following surgery, had a short period of mild biliary regurgitation and at that time x-ray was negative for recurrent ulcer and now two years after surgery that patient is free of symptoms. One patient had a transcient episode of very mild dumping which was not disabling and was relieved by the usual conservative method. All patients have estimated their results as good or excellent. The summary of a number of reports or series to be found in the literature is presented in Table II. It is interesting to note that overall recurrence rates of ulcers run from 1 per cent to 15 per cent, the latter reported by Goligher[7] in a series of 148 duodenal ulcers. Walters, Lynan, et al,[8] reported a high recurrence rate occurring in 237 cases with 5

currences. While no effort here is made to compare directly recurrence rates between Billroth I and Billroth II procedures, certainly any recurrence rate above 5 per cent would reflect poorly when compared with the usually reported recurrence rate after Billroth II. I think that the study of the mortality rate will show that all cases are comparable when one takes into account the years in which the procedures were performed. In reporting 207 cases, Horsley and Barnes[9] showed an overall mortality rate of 8.7 per cent. However, in the cases performed since 1946, the mortality rate was only 1.5 per cent. Also in studying Table II, the wide range in evaluation of excellent and good results as well as the wide range in percentage showing some degree of dumping after the Billroth I is striking. Harkins, who perhaps has been one of the most enthusiastic advocates of the Billroth I procedure, favors a 75 to 80 per cent resection, and certainly his cases are striking. However, the criticism is often leveled at the fact that a large number of his follow-ups are of shorter length as compared to follow-ups in the series reported by Walters. However, Harkins does show a 5.3 per cent of dumping which includes mild cases, a mortality rate of 3 per cent, an overall 1.1 per cent recurrence rate, and 96 per cent of excellent or good results.

Hoar[10] has recently reported eighty cases of 85

to 90 per cent gastrectomy of which thirty-two patients had gastroduodenostomy. In these patients, all the lesser curvature and all but 2.5 inches of the greater curvature were removed. There were no recurrences of ulcer in his series with a follow-up of six months to three years. There was no mortality. Eighty-two per cent of the patients had excellent to good results. The remainder had fair results but were in no way incapacitated. Doctor Hoar concluded that the gastroduodenostomy was a far better procedure because 44 per cent of the patients with this anastomosis had no symptoms, while only 23 per cent of the patients with gastrojejunostomy had no symptoms, and dumping was less frequent and severe in the gastroduodenostomy group. He stated that this extent of the resection should lower the serum pepsinogen to the 200 tyrosine unit level and that in other reports marginal ulceration has been associated with levels above 300. It is his conclusion that if gastroduodenostomy is done for duodenal ulcer, at least 85 per cent of the stomach should be resected.

Summary

1. The theoretical considerations favoring the Billroth I procedure for peptic ulcer are briefly discussed.

2. A small series of twenty cases was reported without recurrent ulceration or serious morbidity. While the results are encouraging, the number is too small and the follow-up too short to be conclusive.

3. A number of series of Billroth I procedures reported in the literature are reviewed. In the light of the overall experience, it would seem that the following conclusions are warranted:

(a) The Billroth I procedure may well provide a better nutritional status for the patient.

(b) Because of the preponderance of evidence showing a high recurrence rate when this is performed for duodenal ulcer, this operation might best be reserved for those cases in which gastric ulcer is present or in which there is some overall reason weighing against performance of a Billroth II type procedure. There may be some evidence that 75 to 80 per cent resection will help protect against the increased recurrence rate following duodenal ulcer.

(c) Fifty per cent gastrectomy with gastroduodenostomy and vagotomy may ultimately offer a superior surgical approach to this complex problem.

Dragstedt, in a recent editorial in *Archives of Surgery*, maintained that his work on the intestinal phase of gastric secretion suggested from the physiological point of view that the Billroth I operation is superior to the Billroth II for acid media entering the duodenum from the stomach inhibit gastric secretion and thus tend to negate the intestinal phase. However, when the food from the stomach enters the jejunum directly, the intestinal phase of secretion is stimulated.

Juvenile Rheumatoid Arthritis

BERNARD M. NORCROSS, M.D.
Buffalo, New York

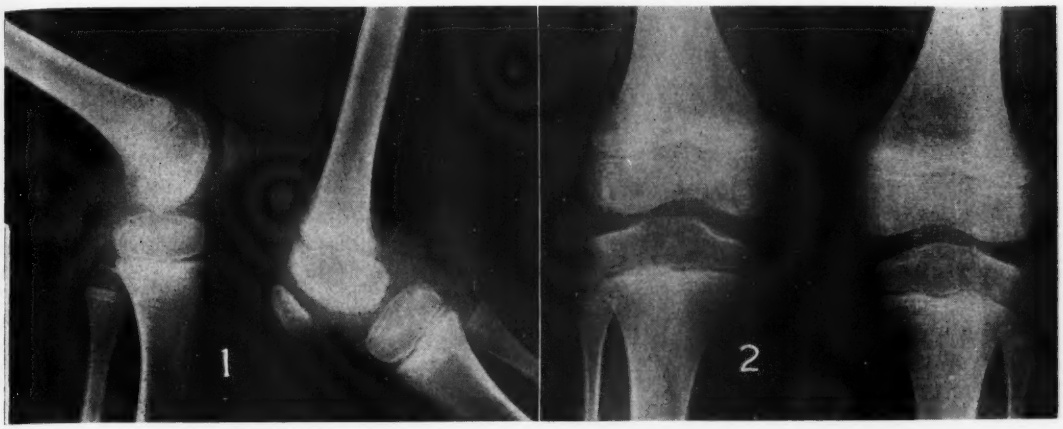

Fig. 4. Roentgenogram of cervical spine and jaw of a girl, age eighteen, illustrates the failure of normal mandibular development.

From the University of Buffalo College of Medicine, Arthritis Clinics of the Buffalo Children's Hospital and Buffalo General Hospital. This paper is published in greater detail in "Progress in Arthritis," Grune & Stratton.

Many reports on juvenile rheumatoid arthritis paint a particularly black picture because of experience with hospitalized patients. This report of sixty-two patients from a combined out-patient and hospital experience gives encouragement about the prognosis in patients receiving conservative therapy.

IN 1897, Still reported such unusual findings in children with rheumatoid arthritis that he believed they constituted a distinct disease (Still's disease).[1] Girls were more frequently affected than boys. The onset was usually insidious with a continuous low or intermittent fever, and not related to joint symptoms. Profuse sweating and mild anemia were common. The characteristic clinical findings included retarded physical growth, marked muscle wasting and absence of joint pain. The joints most frequently involved were the knees, wrists and cervical spine. Still attached much importance to enlargement of the lymph nodes and splenomegaly, the absence of osseous and cartilagenous changes, and involvement of serous membranes (pericarditis and pleurisy). These findings constituted the chief argument in establishing a new clinical entity.

It is difficult to believe that there is any valid reason to consider "Still's disease" as a different

Figs. 1 and 2. Roentgenograms of the knees in a boy, age eight, demonstrate the "wooly" subchondral bone outgrowths of early rheumatoid arthritis.

Presented in the annual postgraduate course, University of Buffalo, September 14, 1959, and the American College of Physicians postgraduate course, October 5, 1959.

entity than rheumatoid arthritis. Bone and cartilagenous destruction do occur and there is no fundamental difference in the anatomical or pathological lesions of "Still's disease" and rheumatoid arthritis. Many gradations of severity of the disease develop in recurrent attacks. Moreover, one of the distinctive findings in juvenile rheumatoid arthritis, that is, abnormal bone development, is merely the result of the disease upon the growing epiphyses. Because only a few large series of patients have been reported, marked discrepancies exist in the knowledge of the course and result of the disease in the average patient. We hope to clarify some of these differences in the following report.

Incidence

If one judged by the paucity of large series of juvenile patients in the medical literature,[2-12] it would be reasonable to assume that this disease is rare. However, it is our experience that rheumatoid arthritis in children is more frequent than previously believed. In a twenty-year period (1935-1955), eighty patients with juvenile rheumatoid arthritis were observed by us, an incidence of 2.7 per cent of all cases of rheumatoid arthritis. Since this group includes ambulatory office patients as well as hospitalized patients, we believe that it represents a faithful picture of the average incidence and course of this disease. The results are based upon the course of the disease in sixty-two children who have been studied periodically for more than seven years.

Sex and Familial Incidence

In universal agreement as to the greater frequency of juvenile rheumatoid arthritis in the female sex, most authors have determined the ratio to be two to one,[2,4,5,12,13] which coincided with our group of forty-one females and twenty-one males. A familial occurrence of rheumatoid arthritis or rheumatic fever, as high as 30 per cent,[2,7,8] has been demonstrated in several series. However, we found only six patients (10 per cent) who had close relatives with rheumatic fever or rheumatoid arthritis.

Age of Onset

General agreement places the peak incidence of onset before or during the third year, followed

Fig. 3. Roentgenogram of the wrists in a boy, age ten, demonstrates abnormal carpal development.

tions should be considered only as a precipitating, rather than the causative factor. The frequency of respiratory disease (especially due to hemolytic streptococci) just prior to the onset of rheumatoid arthritis is almost as impressive as in patients with rheumatic fever. In several reported series, the incidence of prior respiratory infections varied from 45 to 57 per cent.[2,6,10] In our series, 35 per cent of the patients had a history of an antecedent respiratory infection with hemolytic streptococci recovered from the throats of all except three.

Figs. 5, 6, 7, 8. Roentgenograms of the pelvis illustrate the progressive arthritic changes and malformation of the left femoral head and acetabulum in a boy from age six to seventeen.

by a secondary rise between the eighth and eleventh years of life.[2,4-7,13] In our series, onset occurred before the third year in 56 per cent, and symptoms first appeared between the eighth and eleventh years in 30 per cent. In one patient, our youngest, the disease began during the tenth month. This case is not unusual since Sury[4] reported eight patients who developed their disease during the first year. Patients over twelve years of age at onset were not included because they reacted in a pattern typical of the disease in adults.

Precipitating Factors

Since the etiology of rheumatoid arthritis is not known, it is believed that upper respiratory infec-

In our opinion, trauma to a joint is of questionable etiologic significance (less than 10 per cent of our patients). We believe it is only coincidental and not the cause of rheumatoid arthritis in children. The possible relationship of a hereditary factor in juvenile rheumatoid arthritis was not apparent in our group.

Type of Onset

The mode of onset was insidious in forty-six (74 per cent) of the patients with painless swelling of one or more joints and minimal constitutional reaction. Fever, anorexia, weight loss and anemia were mild but were observed in ten of this group. In the remaining sixteen patients (26 per cent),

TABLE I. SYSTEMIC MANIFESTATIONS IN TWENTY-SIX PATIENTS

Fever	26
Anemia	23
Weight loss	22
Interference with osseous growth	12
Carditis	12
Lymphadenopathy	10
Splenomegaly	9
Hepatomegaly	5
Ocular involvement (scleritis, iridocyclitis)	5
Paralytic ileus	1

the onset of the disease was acute, with severe and impressive symptoms. This group of children developed high or prolonged fever, severe anemia requiring transfusions, cardiac abnormalities, marked weight loss, enlargement of the spleen, lymph nodes and liver. They were seriously ill, had a protracted illness with frequent recurrences, and usually experienced a poor final result.

TABLE II.

Joint First Involved		Later Involvement During Course of Disease	Total Involvement
Knee	36	22	58
Hand	5	32	37

	62		

Constitutional Reactions

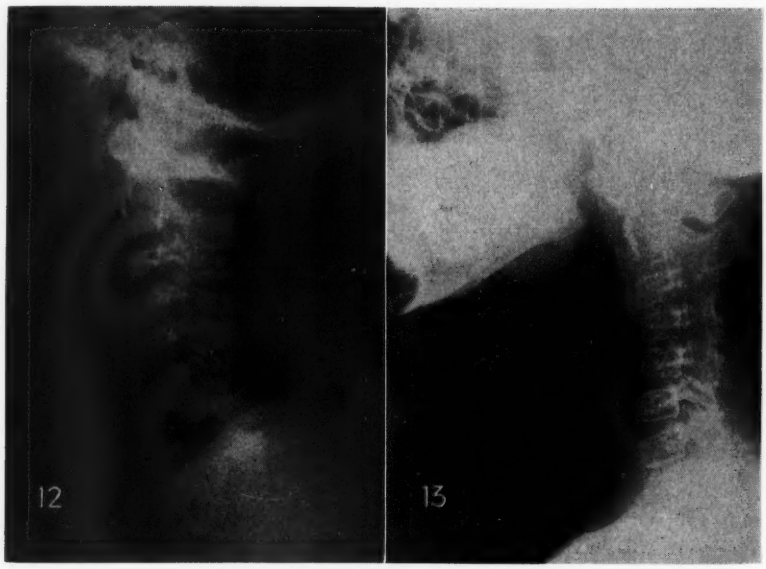
Systemic manifestations were present in twenty-six of our patients (40 per cent). The systemic findings and their incidence are shown in Table I.

TABLE III. ACTIVITY OF RHEUMATOID ARTHRITIS

	Number of Patients		Duration of Activity
One period only (forty-one patients)	17 18 6		1-2 years 3-6 years 7-10 years
	Patients	Number of Attacks	Duration of Activity
Multiple periods of activity (twenty-one patients)	9 6 4 2	2 3 4 5	3 to 20 years

Loss of weight was a frequent early finding but usually approached normal when the activity of the disease subsided. Failure of normal growth was observed in six patients, but two regained normal height when the disease became inactive. Four patients had permanent defects as a result of premature epiphyseal fusion or because of accelerated growth.

Fig. 9. Roentgenogram of the same boy at age seventeen illustrates the failure of normal mandibular growth and also fusion of the posterior articulations of the second and third cervical vertebrae.



The occurrence of murmurs, friction rubs and electrocardiographic abnormalities was observed in twelve patients; two patients developed cardiac failure during acute episodes. Postmortem findings of severe pancarditis (similar to rheumatic fever) were present in two of the three fatalities. Six of the twelve patients later revealed no evidence of cardiac involvement, but the three remaining patients have developed valvular disease (two aortic and one mitral stenosis).

Initial Joint Involvement

Juvenile rheumatoid arthritis had a predilection for initial involvement of large joints, especially the knee, in younger patients. In older children who are approaching puberty, there is a higher incidence of initial involvement of small peripheral joints, similar to adult patients. Frequency of joint involvement in our group of sixty-two children is tabulated in Table II.

Figs. 10 and 11. Roentgenograms of the knees in a girl, illustrate the marked progression of arthritis from age seven to ten.

Figs. 12 and 13. Roentgenograms of the cervical spine in the same girl, demonstrate fusion of the second to the fifth cervical vertebrae and subluxation at C5 and C6 (age seven to twelve).

In six patients (9 per cent), only one joint was involved during the course of the disease. Monarticular involvement of the knee occurred in four patients; the hip and ankle joint were affected in the other two patients. Four patients had migratory joint symptoms resembling rheumatic fever, before definite evidence of rheumatoid arthritis was apparent.

Duration of Activity of the Disease

The average duration of activity was five and one-half years in our patients, but recurrences of the disease were observed for periods as long as twenty years. Forty-one patients (66 per cent) had only one period of activity while twenty-one patients (33 per cent) had multiple periods of activity.

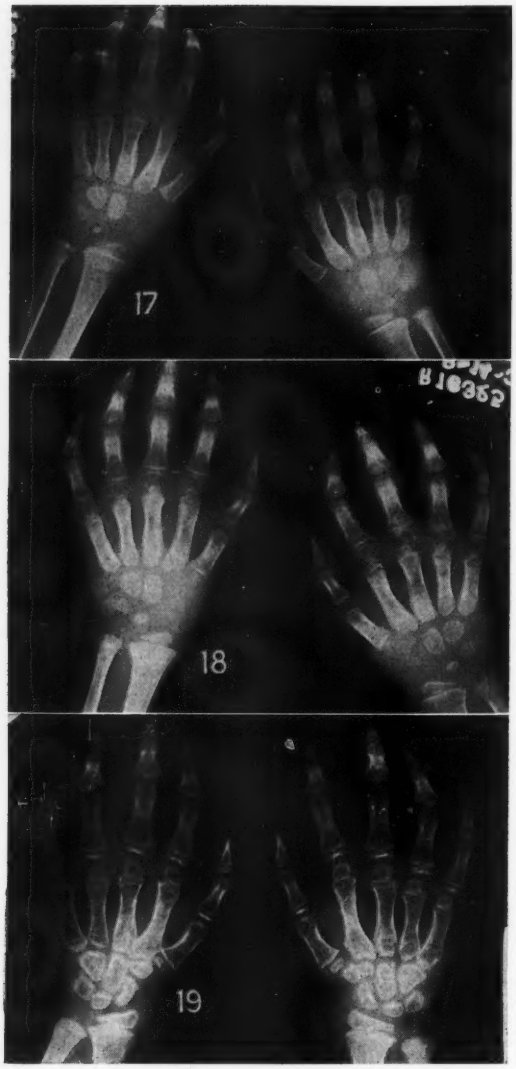
Reactivation of the disease followed upper respiratory infection due to H. streptococci in seven patients. Severe trauma produced a recurrence in three patients after the disease had been inactive in two persons for ten and twelve years. One patient had a recurrence of the disease following pregnancy after sixteen years of quiescence.

Differential Diagnosis

Juvenile rheumatoid arthritis was confused with other diseases in more than one-third of our patients. The greatest difficulty occurred in the differential diagnosis of rheumatic fever in twelve patients. The clinical picture of rheumatoid arthritis rapidly became apparent in eight patients, although six subsequently developed cardiac lesions. In six patients with monarticular involvement, it was possible to exclude specific infectious arthritis (especially tuberculosis) by means of aspiration of a joint and culture of the fluid, tuberculin test, and biopsy of the synovia. Leukemia was considered presumptively in three patients and osteomyelitis was suspected in two patients.

Treatment

Treatment of juvenile rheumatoid arthritis does not differ from that of adults. This program employs the same fundamental measures of bed rest, physical medicine, supportive therapy for general health, orthopedic procedures to prevent or correct deformities, and in some patients, the administration of gold salt or hormones. The most effective treatment in our experience has been prolonged bed rest in combination with injections of gold salts and physical therapy, when this program can be carried out intelligently in the pleasant atmosphere of the home. Complete bed rest is continued until all evidence of joint inflammation has subsided.



The evaluation of drugs (chrysotherapy or hormones) is difficult because the disease is often self-limited and subject to remissions or recurrences. Chrysotherapy was administered to thirty-five patients (weekly injections of 10 to 20 mg. until a total of 600-900 was given); twenty-three patients (65 per cent) improved during the period of gold treatment. In twenty patients, corticotrophin or adrenal corticosteroid therapy was given. All patients had prompt relief of constitutional and arthritic symptoms, and suffered no serious side effects. There can be no question but that hormone therapy diminished the severity of the disease in every patient. The only discouraging factor was the radiographic demonstration of progressive arthritic changes in five patients, despite marked clinical improvement. However, it is our belief that hormones are of benefit in juvenile rheumatoid patients with severe involvement of joints and constitutional symptoms. Hormone therapy was not used in patients with mild juvenile rheumatoid arthritis for they responded well to conservative therapy and chrysotherapy.

Figs. 14, 15, 16. Roentgenograms of a girl, illustrate the severe arthritic deformities that resulted in a seven year period following onset at age seven. There is fusion of both hips, knees, ankles, feet, wrists, and hands. Premature fusion of one epiphysis with stimulation and overgrowth of the other produced bizarre deformities of both the upper and lower extremities.

Prognosis and Results

The prognosis of juvenile rheumatoid arthritis in this group was not as pessimistic as the original

Figs. 17, 18, 19. Roentgenograms of a boy, age three, demonstrate the periosteal accretion of bone in the phalanges during a five month period and resorption of the new bone eighteen months later.

description by Still[1] or the recent report by Barkin[2] would indicate. An explanation for the "poor" results is that their series included a high incidence of severe cases requiring hospital care and excluded the mild patients encountered in office practice.

Factors Which Affect Prognosis

The prognosis of juvenile rheumatoid arthritis was unfavorably influenced in patients with prolonged duration of activity or an acute onset with severe constitutional reaction to the disease. There was no apparent relation of the ultimate prognosis to the age at onset or to the sex of the patient.

Cause of Death

Three patients have died. In addition to severe rheumatoid arthritis, pancarditis and amyloidosis, one had pulmonary tuberculosis, and the second had staphylococcus septicemia with multiple abscesses. The third who died in another hospital of an acute, exsanguinating hemorrhage (at her menarche) did not have an autopsy but was believed to have amyloidosis and carditis on previous examinations.

TABLE IV.

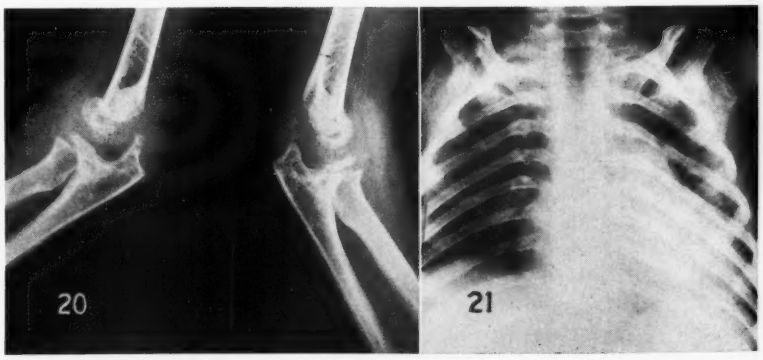
Died	3	3	4.8%
		14	22.5%

Interference with Normal Osseous Growth

Complex and bizarre effects were observed on the normal pattern of osseous growth. These changes include premature fusion of epiphyses with failure of normal bone growth, stimulation of epiphyses with excessive growth, periosteal growth along the shaft of the phalanges, and abnormalities resulting from a combination of these factors and the arthritic process.

Table V lists the regions of the osseous growth disturbances in twelve patients (20 per cent).

Summary



Juvenile rheumatoid arthritis is a chronic joint disease of children associated with systemic manifestations in 40 per cent of the patients. The peak incidence occurs during the first three years of life, with a secondary rise between the eighth and eleventh years. The most important precipi-

tating cause of the disease is a preceding respiratory infection (when associated with the hemolytic streptococcus).

The course of juvenile rheumatoid arthritis is variable. The disease is often mild with a duration of less than two years in 25 per cent of the patients. Joint and systemic involvement are severe in another 25 per cent of the patients and the disease may continue to be active with frequent recurrences for twenty years or more. The average duration of activity was five and one-half years after onset in this series.

The ultimate prognosis of the disease was determined by the type of onset and by the duration of activity or frequent recurrences. The sixteen patients (25 per cent) who had an acute onset with severe constitutional symptoms suffered the poorest result. The prognosis for functional recovery is good (77 per cent). Abnormal bone development resulted from the effect of the arthritic process on the growing epiphyses in approximately 20 per cent.

The treatment of juvenile arthritis is the same as in the adult form of rheumatoid arthritis. Prolonged bed rest combined with chrysotherapy and adequate physical therapy produced the best results. The judicious use of hormones definitely reduced the morbidity of the disease in severely involved patients. When hormone therapy was carefully eliminated, no exacerbations of the disease were encountered.

Figs. 20 and 21. The severe destructive changes of the elbow joints and the marked cardiomegaly are illustrated in the same boy at age five.

Ectopic Pregnancy

A Report of 219 Cases

DALE R. DUNNIHOO, M.C.
WILLIAM MASTERS, M.D.
St. Louis, Missouri

From the Department of Obstetrics and Gynecology, Washington University School of Medicine, St. Louis, Missouri.

ECTOPIC pregnancy, by definition a gestation occurring outside the uterine cavity, may be met by the gynecologist as an acute and obvious emergency, or it may present a difficult diagnostic problem. Frequently a ruptured corpus luteum cyst, threatened intrauterine abortion, or pelvic inflammatory disease may most successfully mimic this condition. In recent years the more widespread use of such techniques as culdocentesis, culdoscopy and colpotomy, as well as the attitude of "ectopic awareness," has materially aided in effective diagnosis and treatment.

Ectopic pregnancy may occur in the tube, ovary, abdominal cavity or in the cervix. There will be different clinical symptoms, depending upon the site involved. Within the tube, nidation may take place in the ampullary, isthmial, or interstitial segments. Ampullary involvement may either terminate by rupture or by abortion through the end of the tube. Isthmial implantation will almost invariably result in early rupture due to the restricted diameter of the tubal lumen. Finally, involvement of the interstitial portion may rupture into the uterine cavity, into the abdominal cavity, or into the broad ligament. The development of an ovarian, abdominal or cervical implantation is a most infrequent occurrence.

Material

During the ten year period ending January 1, 1958, there were 219 patients, in whom ectopic pregnancy was proved at surgery, were admitted to Barnes and the St. Louis Maternity Hospitals. There were no mortalities. During this period, there were 40,361 deliveries giving an incidence of 1:184 (0.54 per cent). Others have noted a somewhat higher incidence, 0.93 per cent,[1] 0.77 per cent,[2] 0.74 per cent,[3] 0.72 per cent,[4] and 0.62 per cent.[5]

Etiology

Any factor which prevents or delays the passage of the ovum to the uterine cavity may be responsible for ectopic gestation. Infections, secondary to abortions, post-partum endometritis, or gonorrheal salpingitis may impede passage of the ovum by adhesions or luminal kinking of either the intimal or serosal surfaces of the tubes. Previous pelvic surgery, peritonitis, or endometriosis may also set the stage for ectopic pregnancy. Usually these situations provide partial obstruction from involvement of the serosal rather than the mucosal tubal elements. Transmigration of the ovum from one ovary to the opposite tube has been noted in a significant number of cases. The resulting ectopic implantation is thought to

be due to the advanced development in size of the ovum as a result of delay during migrational activity. Congenital malformations, such as bicornuate uteri with rudimentary horns, as well as the clinically nebulous diagnosis of tubal spasm, may prevent normal progress of the ovum toward the endometrial cavity implantation site.

A relatively high incidence of previous salpingitis in cases of ectopic pregnancy has been reported in the literature. Carrabba and Silberblatt,[2] noted an incidence of only 18 per cent, however, others have noted 27 per cent,[6] 28 per cent,[7] and 29 per cent.[8] In the present study, fifty-seven cases (26 per cent) either gave a history of previous pelvic inflammatory disease and/or had evidence of it at surgery.

Bookrajian and Luther,[6] have reported the incidence of previous lower abdominal laparotomy in 10 per cent of subsequently developing ectopic pregnancies, contrasted with the 30 per cent, as noted by MacFarlane and Sparling.[9] In the present series, a positive history of previous pelvic surgery was obtained in fifty cases (22 per cent).

A positive history of previous abortions has been reported[10] with an incidence ranging from 15 to 32 per cent of the cases. The present series developed a 31 per cent incidence of previous abortion. In addition, 5 per cent of the patients had repeat ectopic pregnancies. This agrees well with other reports.[2,6,7,8,9,11,12]

Transmigration of the ovum was observed in almost a third of the cases previously reported from this institution.[13] In the present study, twenty-one cases, or 21 per cent of those cases in which this observation was made, were found to contain the corpus luteum of pregnancy in the opposite ovary.

Age

Ectopic pregnancy may occur at any time during a woman's reproductive years. However, the greatest incidence has been noted repeatedly to be in the age group of twenty-six to thirty-five years.[2,4,6,14,15] Findings in the present study agree well with those in the literature in that 132 patients (60 per cent) were between twenty-six and thirty-five years, with the youngest eighteen and the oldest forty-four years.

Parity

It has generally been observed that ectopic pregnancy occurs more commonly in patients of low parity. Bookrajian and Luther[6] found that 67 per cent of their patients were para ii or less. Douglas and associates[14] also noted that 65.7 per cent of their patients fell into this group. Our findings were comparable in that 68 per cent were para ii or less.

Physical Symptoms

The typical triad of ectopic pregnancy symptoms consists of pain, amenorrhea, and vaginal bleeding. Of these, pain is the most frequent symptom. Farell and Scheffey[16] noted pain in 100 per cent of their cases, whereas others have recorded 98.5 per cent,[11] 98.4 per cent,[6] 98.7 per cent,[2] 94 per cent,[8] 90 per cent.[7] The complaint of pain was absent in only 5.6 per cent of cases previously reported from this institution.[13] In this study (96 per cent of patients described some pain) approximately half the complaints were recorded as being severe and/or cramping. Pain was localized to one of the lower quadrants in 56 per cent. While the complaint of pain does not have to be present, its absence certainly casts doubt on the diagnosis.

The pain symptom complex varies considerably. The symptoms may be described as sharp and stabbing, dull and aching, or any variant of these basic patterns. There may or may not be complaints of the cramping type of distress. Usually the pain is confined to one of the lower abdominal quadrants. However, the distress may be bilateral, or even generalized over the entire abdomen. Quite frequently the pain complex may be referred into the back, the rectum, the diaphragm, or to the shoulders as the result of peritoneal irritation. Shoulder pain has variously been reported as 0.7 per cent,[7] 8.5 per cent,[11] 11.3 per cent,[12] and 26 per cent.[2] In this series, fifty-three patients (24 per cent) described this referred complex symptom. Half of the patients noted unilateral shoulder pain only, usually on the same side as the involved fallopian tube.

Menstrual irregularity is certainly the second most common finding in the clinical picture of ectopic pregnancy. The typical history is one of a missed period followed two to three weeks later by vaginal spotting with the subsequent onset of pelvic pain. Amenorrhea of over one month's duration was noted in 144 patients (65 per cent), and intermenstrual bleeding in 185 cases (84 per cent). A combination of both a period of ame-

norrhea followed by intermenstrual bleeding was noted in 125 patients (57 per cent). These observations agree well with those reported in the literature in regard to amenorrhea, 42.5 per cent,[1] 52 per cent,[17] 64.5 per cent,[11] 75 per cent,[8,9] and in intermenstrual bleeding, 90 per cent,[9] 87 per cent.[4] It has often been stated that the vaginal bleeding of ectopic pregnancy is mild in comparison to that of abortion. While this is a good rule of thumb, it should not be relied upon completely, as the vaginal bleeding may be quite profuse subsequent to death of the ectopic gestation, and the loss of decidua from the intrauterine cavity.

Syncope and weakness have been recorded in up to 40 per cent of the cases in the literature: 3 per cent,[18] 12.5 per cent,[1] 17 per cent,[16] 25 per cent,[2] 29.1 per cent,[11] 35.4 per cent,[9] 36.4 per cent,[17] and 40.8 per cent.[6] These symptoms were recorded in 44 per cent of the present series, 17 per cent of whom noted syncope.

Symptoms of pregnancy, with some part of the typical triad of nausea and vomiting, breast changes and increased frequency of urination were present in 50 per cent of the cases studied. Breast changes occurred in 61 per cent, nausea and vomiting in 58 per cent, and increased frequency of urination in 39 per cent.

Physical Signs

A number of findings on physical examination in ectopic pregnancy are worthy of note. Abdominal tenderness has been noted to be present in all the cases reported by Davis and Malloy,[1] while others have noted 93 per cent,[16] 90 per cent,[8] and 81 per cent.[17] This complaint was recorded in 196 patients (89 per cent) of those studied to develop this report.

Tenderness of the cervix on motion has been regarded as a valuable sign in ectopic pregnancy. Crawford and Hutchinson,[8] reported this in 31.6 per cent, and Bookrajian and Luther,[6] in 44 per cent of cases. Cervical tenderness was recorded in 41 per cent of the cases in this study.

Uterine enlargement was noted in 47 per cent of our patients. However, others have reported 12.5 per cent,[1] 25 per cent,[8] 29 per cent,[16] and 46.3 per cent.[9]

Cervical signs of pregnancy were found to be present in one half of our cases. Cervical softness was present in 39 per cent, and a positive Chadwick's sign was noted in 31.5 per cent.

Fullness of the cul-de-sac was noted in 58 per cent of our patients. Langman and Goldblatt[10] also noted this in over 50 per cent of their cases.

Laboratory Determinations

Whereas others[8] have noted positive pregnancy tests in as high as 75 per cent of instances, no more than 50 per cent of the present series recorded positive pregnancy tests. For this reason, we feel that the frog test is of little value in ectopic pregnancy. If positive, it may lend support to a considered diagnosis of ectopic pregnancy. However, no reliance should be placed upon a negative pregnancy test. Under no circumstances should a diagnosis of ectopic pregnancy be rejected purely on the basis of a negative pregnancy test.

Hemoglobin and red cell counts are of significance primarily when repeated tests over a period of observation show decreasing values. Occasionally the presence of an anemia, with a hemoglobin of under 10 grams (demonstrated in only 39 per cent of the cases studied), may be of value in defining the overall clinical picture.

Crawford and Hutchinson[8] noted a leukocyte count of over 10,000/c.mm. in 90 per cent of their 132 cases, with only 12 per cent being over 20,000/c.mm. Leukocyte counts in our cases revealed that 68 per cent had less than 12,000/c.mm. and 84 per cent less than 15,000/c.mm.

Procedures

Temperatures were recorded prior to surgery in all but thirteen patients. A temperature of 37.5° C or less was found in 80 per cent, with 95 per cent having a temperature of less than 38° C. This agrees well with the values noted by others.[8]

One of the most definitive tests for ectopic pregnancy is that of culdocentesis. This was carried out in 103 cases, with positive results in 92 per cent. Others[8] have reported a similar incidence. The procedure is simple and can be performed in the outpatient clinic without difficulty or complications.

Colpotomy is a valuable diagnostic as well as a therapeutic procedure. Occasionally, in those cases in which the diagnosis is borderline with a negative culdocentesis, a colpotomy may be performed, with a minimum of operative trauma to the patient. If present, the tubal pregnancy

may frequently be removed through the colpotomy incision. This procedure was carried out in only six of our cases.

Culdoscopy is also a useful procedure in ectopic pregnancy, and has its primary use in the patient with longstanding symptoms. This procedure was used in only two cases in this series.

A diagnostic dilatation and curettage was performed in forty-seven cases with a decidual reaction noted in 45 per cent and normal interval endometrium in 35 per cent. Crawford and Hutchinson,[8] noted a decidual reaction in 27 per cent of their cases.

Occasionally, it is necessary to do an examination under anesthesia in order to reassure the operator that he is making the proper diagnosis. This is particularly true in those patients who are experiencing too much pain or are too obese for an adequate pelvic examination. This procedure was carried out in 55 per cent of the cases. If the diagnosis of ectopic pregnancy is entertained on the basis of positive history or physical findings, it is up to the physician in charge to make a definitive diagnosis regardless of the extent of the laboratory or diagnostic procedures deemed necessary to satisfy his medical curiosity.

Diagnosis

The diagnosis of ectopic pregnancy is at best a difficult task. So many conditions may mimic this disease that only constant awareness of the possibility of its presence will be of assistance in making a correct diagnosis. In short, any physician dealing with women in the childbearing ages should be "ectopic conscious."

A differential diagnosis of ectopic pregnancy should include consideration of (1) corpus luteum cyst, (2) pelvic inflammatory disease, (3) threatened abortion, (4) ovarian cyst with twisted pedicle, and (5) appendicitis. Of course many other conditions may also develop symptoms similar to those of ectopic pregnancy. However, the clinical concerns listed above are the most prevalent situations that may be confused with the primary diagnosis.

Whenever the diagnosis of ectopic pregnancy is strongly suspected, certain procedures should be carried out in order to establish the diagnosis. A hemoglobin and/or hematocrit should be determined to detect any existing anemia, and also to serve as a baseline for further evaluation of later blood loss. Leukocyte counts and evaluation of the temperature serve to differentiate any infectious processes. Of major importance is the performance of a culdocentesis. Aspiration of non-clotting blood from the cul-de-sac usually narrows the diagnosis to either an ectopic pregnancy or a ruptured corpus luteum cyst with intra-abdominal hemorrhage. Both of these conditions may necessitate surgical intervention to determine the source and amount of hemorrhage.

The incidence of correct preoperative diagnosis of ectopic pregnancy in the literature is slightly over 80 per cent.[4,8,11,14] In the present series 193 patients (88 per cent) were correctly diagnosed preoperatively. In 104 of these cases, the diagnosis was so obvious that only the diagnosis of ectopic pregnancy was considered.

Operation

The presence of shock preoperatively has been noted in a varied percentage of cases. Bookrajian and Luther[6] recorded shock in 35 per cent, whereas Carrabba and Silberblatt[2] noted this in only 10 per cent. Others have noted 15 per cent,[4] 21 per cent,[16] 25 per cent,[9] 27.5 per cent,[1] and 33 per cent.[7] A blood pressure (systolic) of less than 100 was noted in eighty-eight (40 per cent) of the cases in this series.

In 158 cases, the amount of abdominal bleeding was estimated at the time of operation. Less than 500 cc. of blood were encountered in 55 per cent of these cases. Crawford and Hutchinson[8] also noted less than 500 cc. present in 47 per cent of their cases, with 26 per cent having over 1000 cc.

As may be expected from the foregoing data, transfusion became a necessity in 61 per cent of the patients, of whom two-thirds required multiple transfusions. As a general rule of thumb, if a patient needs transfusion during the course of an ectopic pregnancy, one unit (500 cc. whole blood) will not be sufficient for adequate patient protection.

Laparotomy was performed on the day of admission in 139 cases (63 per cent), while in another fifty-one cases (23 per cent), it was carried out within a second twenty-four hours after admission. Because of the uncertainty of the diagnosis, the remaining 14 per cent of patients were observed for varying periods up to a week before surgery was performed.

Throughout the literature it has been noted that ectopic pregnancy occurs predominantly on

the right side; 64 per cent,[14] 63 per cent,[9] and 53 per cent,[8,19] The preponderance of right-sided involvement was again demonstrated in this study, with 61 per cent occurring on the right side. Tubal abortion or rupture was also more prevalent on the right side (61 per cent). In four cases evidence of an old ectopic pregnancy was found on the opposite side from the side of acute symptomatology.

The most common site of involvement is generally stated to be in the ampullary portion of the tube.[7,8,9] In the series under consideration, the ampullary portion was involved in 77 per cent, the isthmial in 10 per cent, and 7 per cent were found in the cornual area. In the remainder of cases, the site of implantation was either not recorded or could not be determined from the pathologic report.

The operative procedure most commonly performed was the removal of the involved tube only, with preservation of the ovary whenever possible. Unilateral salpingectomy was done in 144 cases (66 per cent). Removal of both the tube and the ovary, often because of adhesions and involvement of the ovarian blood supply, was carried out in fifty-three patients (24 per cent). In 7 per cent, a partial salpingectomy, and in 1.5 per cent, a tuboplasty was performed in well-localized ectopics without extensive involvement of the tube. In one case, ligation alone was performed, and in one other the tube was milked and left intact. Bilateral salpingectomy was carried out in sixteen cases, for coexisting old ectopics, dermoid cysts, hydrosalpinx, and as part of the procedure during hysterectomy for myomatous uterus and cervical cancer.

The appendix was removed in forty-eight cases (22 per cent), once for subacute appendicitis, the remainder as incidental procedures. This is a relatively high rate of incidental appendectomies, in view of the reports in the literature.[8,20] We have, however, noted no unsatisfactory results from this technique in these cases.

Postoperative Complications

Postoperative complications such as unexplained fever, upper respiratory infections, cystitis, ileus, transfusion reactions with urticaria, and minor stitch abscesses were noted in approximately one half of the patients. Of these, unexplained fever was present in 70 per cent, and was usually of low grade. In general, it was felt by the attending physicians to be due to the resorption of blood from the peritoneal cavity. Crawford and Hutchinson[8] have also noted a 55.67 per cent incidence of unexplained fever postoperatively.

Summary and Conclusions

We have presented a series of 219 cases of ectopic pregnancy that have been proven at surgery at Barnes and St. Louis Maternity Hospitals during the ten-year period ending January 1, 1958. A comparison of results was made with some of the reports in the literature. While some of the figures are in the same range as these reports, there are some notable exceptions, for example, the incidence of transmigration of the ovum differs widely from most reports. We have made no attempt to interpret our findings, but merely seek to add them to the growing body of knowledge concerning ectopic pregnancy.

Varieties of Tuberculosis in Children

JOHN S. CHAPMAN, M.D.
Dallas, Texas

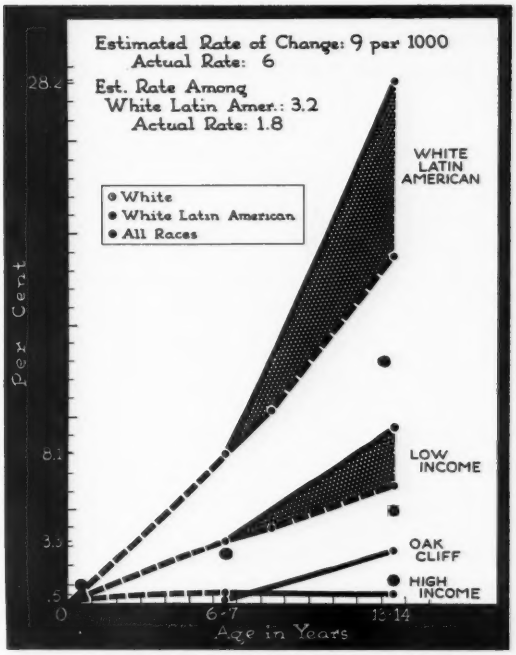

Fig. 1. Tuberculin skin-testing program in selected areas in the city of Dallas. Tests in 1956, 1957, and 1958 at age of six to seven, and thirteen to fourteen. Shaded areas represent differences between projected rates of infection in 1956, and rates of infection actually found in 1957 and 1958. Large black dots represent actual infections in thirteen to fourteen-year-old children in 1958.

Isoniazid has produced significant alterations in the course of tuberculosis in children.

TUBERCULOSIS is a pathological term that signifies the formation of a certain type of tissue reaction. This reaction is common to many agents, some living, some non-living. Tuberculosis as used in the present discussion refers only to the tissue changes that result from infection with M. tuberculosis, and chiefly from the variety hominis. Closely related mycobacteria, the "anonymous" strains as grouped by Runyon, however, produce lesions and disease in most respects hardly differ-

entiable from tuberculosis and sometimes even so designated.

The varieties of tuberculosis as they occur in infants and children are fairly classic in their manifestations. The first consists of a primary pulmonary lesion, almost always very quickly associated with extension to the draining lymph node of the bronchial group. The second phase of the disease is associated with the development of allergy, the necrosis of tissue and the secondary effects that result from such necrosis. Among these may be mentioned cavitation of the original pulmonary lesion and rupture of lymph nodes into adjacent bronchi or vessels. The third variety commonly encountered is hematogenous dissemination, either in the form of occasional mycotic emboli with resultant distant but localized disease, or in the form of an acute bacteremia known as miliary tuberculosis. The fourth variety consists of ordinary tuberculosis of the lung manifesting itself in essentially the same forms as may be found among adults. Finally, a fifth variety, if one accepts the designation, is that form of tuberculosis produced by the anonymous mycobacteria.

TABLE I

Race	Total Population	Hospitalized Children
White	80%	25%
Negro	16%	50%
Latin-American	4%	25%

The background for this sequence of events and this classification has been discussed elsewhere and the pathogenesis of these successive manifestations elaborated upon.[1,2]

The present discussion is drawn from an experience of somewhat more than ten years and hospitalization and personal study of over 200 infants and children. The youngest was six weeks of age and the oldest twelve years (children above that age were managed in other hospitals). Table I indicates the population from which these children were drawn, the figures being given in percentages rather than absolute numbers. Only children who are clinically ill are admitted to the hospital, unless x-ray films or other examinations indicate extensive disease. Most admissions are under the age of three years and from 35 to 50 per cent have evidence of hematogenous disease.

In the usual term of incidence, hospitalization has been calculated to be about 40/10,000 Latin-Americans below the age of twelve years, 3/10,000 Negroes and 1/10,000 whites. These figures, however, refer to the estimated total number of all children. A much more significant figure can be derived from calculating incidence of hospitalization against the number of positive reactors.

Such figures for a time were unavailable, but during the past three years under the auspices of the Dallas Pediatric Society and the Dallas Tuberculosis Association, a method of spot-checking was worked out that allows a fairly reliable estimate of the number of reactors in each of the three groups. For purposes of the test, primary public schools were chosen in the areas of the city in which were the largest numbers of registered cases of tuberculosis, and all first-graders for whom consent could be obtained were tested with Old Tuberculin 1-1000. The results indicate that at the age of six years in areas chosen for "worst" economic and social environment, 2 per cent of white children, 2 per cent of Negro and 8 per cent of Latin-American children reacted to the test dose (Fig. 1). Information from each of the schools tested resulted in approximately the same figures. On the other hand, a school selected for a middle social position resulted in 1 per cent reactors and another chosen for unusually high economic and social environment resulted in 0.5 per cent positive reactors. (In these two schools all students were Caucasians.) If admissions to the hospital are calculated against the estimated number of reactors within the first six years of life, the incidence figures become 1/40 for Latin-Americans, 1/20 for Negroes and 1/100 for whites. Seemingly, the Latin-American or Negro child is not only more frequently infected in early life but also has a higher rate of serious illness. The reasons for these social and economic and racial differences are under study at the present time.

In the entire series, but few children could be classified under the first heading alone, that is, with a simple parenchymal component. Perhaps this is the result of inability to recognize a parenchymal component alone since the x-ray film might well be simply that of a small pneumonic area, and since the disease is essentially without clinical manifestation until allergy and necrosis begin.

By far the commonest admission has been for the second category, the child in whom not only the first draining node, but oftentimes the entire mediastinal group have become greatly enlarged (Fig. 2). In a few such cases, the parenchyma of the lung has been clear, and prolonged follow-up has failed to reveal so much as a fleck of calcium to indicate the site of the pulmonary invasion, though the hilar and mediastinal nodes meanwhile have become heavily calcific. The majority of children become symptomatic at this time and are brought in with complaints suggestive of mediastinal mass and of interruption in air-flow through trachea or bronchi. The films have then revealed segments of lobes completely airless and much contracted, associated with a mediastinal mass. In such children, bronchoscopy, which is a frequent procedure in this service, has revealed either marked distortion and external occlusion of the bronchi or localized and apparently specific bronchitis or both.[3] A few such segments when subsequently resected have presented no pathological evidence of tuberculosis but only the results of bronchial obstruction and secondary pyogenic disease with atelectasis, emphysema, bronchiectasis and fibrosis. The greater part of the parenchymal infiltration in such cases would appear to be non-specific, suppurative inflammation.

The treatment of such a condition in which greatly swollen nodes produce external compression of bronchi has been by and large unsatisfactory from the standpoint of the preservation of the damaged segments, however well the further extension of tuberculosis may be controlled. Bronchograms have revealed residual saccular bronchiectases in a number of cases though the gross shadow of obstructed lung has cleared. The significance of this observation lies in the fact that chemotherapeutic agents for tuberculosis, while they check the multiplication of tubercle organisms, cannot and do not rapidly reduce the size of inflammatory masses such as matted mediastinal nodes.[4]

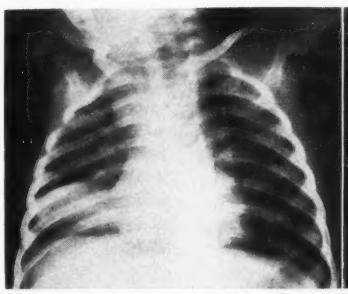

Fig. 2. Characteristic obstruction of bronchus associated with tracheo-bronchial lymphadenopathy in an eighteen-months-old child. (March 7, 1951)

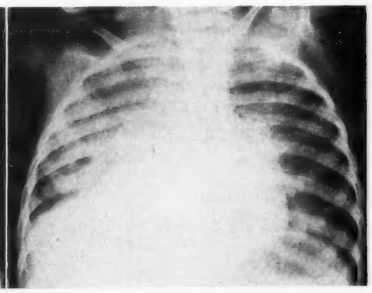

Fig. 3. Complicated primary tuberculosis in a young child. Right lower and middle lobes are obstructed, all mediastinal nodes are enlarged and there is wide-spread dissemination superimposed. (October 22, 1951)

In a number of instances, the infection has spread upward from the right paratracheal nodes to involve the anterior deep cervical group so that masses appear at the base of the neck and, of course, undergo the progressive changes characteristic of tuberculous nodes. It is necessary to make some particular mention of this mode of node-by-node extension to distinguish it from other modes of lymph node infection with the human organism.

Hard upon these manifestations the hematogenous phase develops (Fig. 3). While this experience would hardly support Wallgren's classic time-table for the various manifestations, as a generalization it is probably reliable with respect to the order if not the exact time of appearance. In some twenty cases of tuberculosis of bone, the osseous lesion has not usually developed during the phase of the massive mediastinal involvement. On the contrary, meningitis and pleural effusion have appeared during the presence of mediastinal nodes in over half of these cases. Miliary tuberculosis has also supervened at this time and in the very young infant may develop without the intermediate phase of recognizable lymphatic disease. The youngest such case was eight weeks

old at the time of her admission with miliary lesions. Whether or not pleural effusion should be regarded as a manifestation of hematogenous disease is open to some question. The prerequisite

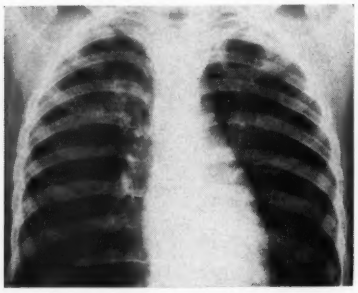

Fig. 4. Usual variety of pulmonary tuberculosis encountered in nine-year-old Latin-American girl. (August 4, 1952)

for its appearance is a subpleural tubercle, a structure which may result either from peripheral spread from a caseating primary site or from hematogenous seeding. In only about a third of the cases of meningitis or pleural effusion has the child been as much as five years of age or had evidence of having healed a primary lesion.

On the contrary, the few instances (about twelve out of 200) of ordinary pulmonary infection encountered have without exception been in children above six years of age and none has been Caucasian (Fig. 4). All have been girls, and the average age is about nine years.

Results of treatment since the advent of isoniazid in 1952, have been outstanding. In the nineteenth century, European writers regularly reported death rates of 25 to 50 per cent in pediatric patients with recognizable tuberculosis. During the period of streptomycin-PAS alone, the writer observed two cases of meningitis to develop in children in the hospital under daily treatment. Meningitis treated with these two drugs resulted in 30 to 40 per cent mortality. Since isoniazid became available, no patient from a much larger group has developed meningitis while under treatment, the mortality from all forms of tuberculosis has been 5 per cent, and a portion of these have resulted from chronic convulsive states long after meningitis as an active process had healed. Miliary tuberculosis has resulted in a single death, that within two days of admission.

Perhaps in osseous tuberculosis the results of isoniazid therapy have been most striking. Reference to old records makes it evident that many younger patients with Pott's disease died either of meningitis or miliary disease. No case of osseous tuberculosis has died. Three cases of Pott's disease, which accounts for half of osseous tuberculosis, have healed without requiring fusions (Fig. 5). Three cases of tuberculosis involving the knee have undergone complete healing with full restoration of the motion of that important joint. It has been possible to drain freely any collection of pus that has been encountered and no persistent sinuses have resulted, nor has any sinus, however deep or chronic, failed to heal.

A review of varieties of tuberculosis in children can hardly be complete without some reference to the disease produced by the anonymous mycobacteria. The disease produced by these organisms in the present writer's view preferably should be called mycobacteriosis, and further classified according to the groups established by Runyon's careful study of hundreds of strains. Of the four groups, Group IV, distinguished by very rapid (two to three days) growth, has so far not been shown to be pathogenic. The other three groups, which are distinguished according to their ability to produce color, have shown definite evidence of varying degrees of pathogenicity and an apparent geographic distribution.

Group I, the photochromogen, which is colorless when incubated in the dark produces a yellow color when a young colony is exposed to light. Strains of this group have been reported most frequently from the central and south central portions of this country. Group II, the scotochromogens, produce orange colored colonies when grown in the dark and only become a little more pigmented when exposed to light. These organisms, less pathogenic than Group I, may also be both less homogenous as to strain and more widely distributed geographically. Group III, the non-chromogen strains, fail to produce color under any conditions. This group may also contain a variety of strains of varying pathogenicity. Most of these organisms reported and identified have come from the Southeastern part of the United States.

The pathological lesion produced by the anonymous strains is not readily differentiable from that produced by the human organism. Some pathologists are of the opinion that lesions tend to be

more liquid and truly suppurative than characteristic lesions of M. tuberculosis.

The drug susceptibility of these organisms is less than that of M. tuberculosis. Group I organisms more closely approach the susceptibility of human strains, but fresh isolates may manifest partial resistance to isoniazid though usually none to streptomycin. Group II and Group III organisms are more variable and usually manifest a higher grade of resistance to the usual antituberculosis agents.

Fig. 5. *(left)* Lateral view of lumbar spine September, 1952, after drainage of large cold abscess. *(right)* Same August, 1954, after two years of therapy with INH-PAS, comparatively little use of supports in the interval.

In spite of these facts, all cases mentioned have been treated with isoniazid and PAS in usual dosages and there have been no relapses or recurrences. It should be mentioned, however, that local excision of nodes has been routine and that the regimen of drugs has been continued for eighteen months.

While these organisms were first observed to produce a tuberculosis-like disease of the lung in adults (somewhat questionable in regard to Group II) the early papers of Weed et al[5] and of Prissick and Masson[6] indicated that organisms other than M. tuberculosis, hominis, caused disease in the lymph nodes of children and Prissick and Masson were able to isolate one such organism from an osseous lesion of a child. The organisms reported by these authors were not studied for group identification. Since then six cases of scrofula caused by such organisms were reported from Dallas.[7] Of these, five were caused by Group I organisms and one by Group II. At the time of the report, the speculation was hazarded that since the nodes usually involved were the tonsillar or submandibular nodes, it might be quite likely that the site of invasion was the tonsil or adenoid, with a less probability that invasion might be through the gingiva during inflammation from dentition. Since that time, an opportunity has arisen to perform cultures on tonsil and an adenoid of a child from whose submandibular node a photochromogen had already been recovered. The tonsil and the adenoid each produced a culture of the same organism so that the oropharyngeal site of invasion seems highly probable.

Since the report, organisms have been isolated from the nodes or drainage of six other children. Two of these have had involvement of other nodes, in one an axillary group, in the other inguinal nodes. A puncture wound of the hand was found in one child and one on the foot in the other. In regard to total strains isolated, one of the strains has been a member of Group II, one of Group III and eight of Group I. (It should

be noted that in the Dallas area, approximately the same ratio of groups to each other has been found in pulmonary disease of adults, while skin-tests with appropriate antigens have also indicated a marked preponderance of reactions to Group I strains.)

In addition to the nodes, one boy with a cyst-like lesion of the distal end of the femur gradually developed a swollen knee. Aspiration revealed pus that contained organisms of Group III morphology and gastric washings produced two separate cultures of Group III organisms. On one of the other services, a somewhat older Latin-American boy died of meningitis from which the only organism recovered was a Group III strain.

Two or three other children have had similar submandibular infections, but though the organisms were readily and frequently seen on smear, cultures failed to result in growth, so that these remain open to doubt.

It is readily appreciated that if such organisms result in disease of bone, joint and meninges, there should be at some time a pulmonary lesion that could be identified as a result of these mycobacteria. None has been reported to the writer's knowledge. There are three cases among recent admissions who may represent such a possibility. One of these children, an older Negro girl, had a severe attack of bronchitis with what was thought to be a very small, lobular pneumonia. Three sputums sent up from clinic were each positive for acid-fast organisms, but culture of all three failed to produce a growth. The child's cough and fever persisted in spite of ordinary antibiotics but diminished rapidly when she was given PAS-isoniazid. The second patient was referred from a suburban town, where her physician, an excellent pediatrician, had found her to have a persistent upper lobe pneumonia that failed to respond to antibiotics. Two sputum smears were made in his laboratory and review by a technician highly trained in the field of mycobacteriology led to a strong suspicion that these were Group I organisms. Culture again failed, but the child recovered rapidly after she was given PAS-isoniazid. The third case, that of an older white girl, was much like the second, except that almost the entire left lung was involved.* Pleural fluid and bronchoscopic aspiration again produced smears containing acid-fast organisms somewhat atypical in morphology. Once again, all types of antibiotics having failed to affect her course, she was given PAS-isoniazid and her pneumonia resolved in about two months.

It should be added that most of these children have reacted in varying degree to tuberculin, though sometimes only to 1 to 100. Their families have been entirely negative so far as chest films are concerned and siblings have had negative tuberculins.

*Since the preparation of this report, a fourth child with pneumonia and pleural effusion has been encountered. The organism cultured from the pleural fluid of this patient was a photochromogen. The clear proof of the etiology of this patient's disease lends support to the suspicion mentioned above.

Summary

1. Tuberculosis in children manifests itself in several varieties, the most common of which is lymph node disease of the tracheobronchial and mediastinal lymph nodes.

2. Often associated with and deriving from this variety is hematogenous disease either of the mycotic embolic or bacteremic type with tuberculous meningitis as its most dangerous manifestation.

3. Isoniazid has produced a significant change in the course of tuberculosis in children.

4. In certain areas infections caused by anonymous mycobacteria may result in confusion, particularly in relation to scrofula, much less frequently in relation to osseous, meningeal or pulmonary disease.

X-Ray Hazards and Common Sense

This concise article is full of common sense regarding x-ray radiation. The attention of all physicians should be drawn to the magnitude of this problem. It is our responsibility to our patients that we protect them against excessive radiation. Protective measures and devices are described in this article.

L. M. HAMMAR, M.D.
Mankato, Minnesota

Presented at the annual meeting of the Southern Minnesota Medical Association, Rochester, Minnesota, September 14, 1959.

"I WILL NOT have my chest x-rayed! I read in the paper that x-rays can produce deformed offspring." This statement by a sixty-three-year-old woman, was actually made when she was urged to have a chest radiograph for a persistent cough. Unfortunately, such beliefs are fairly commonly held. Truths and half-truths disseminated through the lay press, many times in a sensational manner, are eagerly read and often only half understood. The result, then, in the mind of the lay reader, whose knowledge of heredity may be vague at best, is a real fear and a most difficult one to dispel. It is our duty as medical advisors to study the problem, get the facts, and give these patients our best advice.

In order to have a proper understanding of the dilemma facing these patients, let us approach the

situation with a questioning attitude and an open mind. Let us start by asking, is there a real hazard? If so, what is the magnitude? How may a person's health be affected? What may be the effects on coming generations? And finally, how may we minimize the dangers? With answers to these questions, we shall be in a position to give our patients better advice.

I feel particularly fortunate in being able to address this group since this, for the most part, is a meeting of generalists. Most of you, no doubt, have your own x-ray equipment; some of you may be doing fluoroscopic examinations; a few of you are using radium. If you are using any of the above, you are getting some radiation. The tissue effects from any type of radiation are produced by ionization, and to measure these effects it is necessary to have a unit of radiation exposure. This is actually a measure of the ionization produced in a standard volume of air. This unit was devised more than twenty years ago and is known as the roentgen or, abbreviated, by the symbol r. For most purposes in measuring radiation hazards, the unit milli-roentgen or 1/1000 roentgen is used, abbreviated mr. These amounts of ionizing rays can be readily detected and measured right in your office. Certain maximum permissible exposures have been postulated, expressed in the above units.

In attempting to answer the question, is there a real hazard?, it must be determined what harm x-rays do to the body, what hereditary changes may be expected, and whether safe limits of exposure are being exceeded.

The local effects of heavy x-ray exposure are well known; they became evident soon after discovery of x-rays. The pioneers in this field worked with unshielded tubes, producing x-rays of low penetrating power, requiring long exposures. It was not uncommon for both the operator and the patient to develop erythema in areas of skin exposed during diagnostic procedures. After many years, some of these operators developed permanent skin changes such as chronic painful ulcers and skin atrophy. Modern equipment presents few of these problems. Tubes are shielded by a lead envelope, the soft rays can be filtered out, the x-ray beam is of good penetrating quality produced by high voltage. The beam can be coned down to cover only the area of interest and the operator is protected by a leaded wall. Exposures are measured in most instances in fractions of a second. Local reactions are now seen only after therapeutic exposures when they are deliberately achieved.

The general effects of body irradiation are more obscure but have been undergoing intensive study. The changes are often so gradual as to avoid detection. Studies of the life span of individuals exposed to chronic whole body irradiation are not conclusive. The effects on the life span of experimental animals, however, are well established. By assuming that there is a comparable effect on the human body, calculations have been made attempting to relate the experimental results to longevity in man.[1] Values determined by the above means vary greatly. Figures range from a shortening of life by fifteen days per roentgen to one day per r of chronic body exposure.

How does x-radiation work to reduce the life span? Again it must be admitted that the exact mechanism is unknown and assumptions must be made. One of the most reasonable assumptions relates the deleterious effects to somatic mutation. Vast experimental evidence has been accumulated showing the potent effect of x-rays in producing mutations in germ cells. The chromosomes are the vulnerable structures. They are composed chemically of desoxyribose nucleic acid which has a fascinating molecular structure.[2] The molecules are known to be giant sized. Each chromosome consists of thousands of these molecules. The internal structure of this DNA molecule is capable of some variability and this variability offers an explanation of the coding of information for enzymatic control of metabolic processes. DNA resides in the chromosomes of all body cells—somatic as well as reproductive, it is the hereditary material. Changes in this hereditary material will be handed down through mitosis to each succeeding generation of descendant cells. Should these cells be in a strategic location, vital body processes might be impaired and life shortened. X-rays are capable of producing molecular changes through their ionizing properties. The most vulnerable and vital part of the cell would be the giant molecules of DNA in the chromosomes. Chronic body radiation then is probably capable of producing somatic mutation. Through this effect the aging process is accelerated, either through cell death, or inability to carry out its normal function.

What are the hereditary effects produced by x-rays? Again we must seek the answer from

animal experiments. Studies on humans exposed to long term radiation have been done but their scope has been too limited to be of great statistical significance. Questionnaires were sent to radiologists and to a control group of non-radiation exposed physicians by Macht and Lawrence.[3] They found a slightly greater number of stillbirths, neonatal deaths and certain congenital abnormalities in radiologists' children than among non-radiologists' children. It is to be borne in mind, however, that this is a study confined to the first generation of offspring of individuals exposed to chronic radiation, and as yet no studies have shown true hereditary defects produced by radiation induced mutation of human germ plasm carried into the second generation. One of the few studies of second generation offspring of radiated mothers is that of Kaplan,[4] who, since 1925, has treated female sterility with small doses of radiation to the pituitary and ovaries. Of 700 cases treated, 308 women have borne 540 living children. Of these children, thirty-five have grown up, married, and in turn have produced forty-three children. No defects were noted in the second generation. Small as were the doses given to these women, they greatly exceeded gonadal doses during diagnostic radiation. In this connection, I should like to mention a case under my personal observation. A diagnosis of Hodgkin's disease was established by pathological examination of a cervical node in a twenty-three-year-old married woman. Intensive radiation therapy was given to the involved node, but the patient subsequently developed metastases in the mediastinal nodes, ribs, pericecal nodes and spleen, all of which were given roentgen radiation. The amount of radiation reaching the right ovarian region was estimated at 1,200 r and to the left at 100 r. The patient responded well to the above treatment and several blood transfusions. During remission of the disease, she became pregnant and delivered a normal male child, who is now three and one-half years old, and as far as can be determined shows no evidence of any congenital abnormality.

The above cases are quoted, not to minimize the genetic dangers of radiation, but to point out that it is impossible to recognize small mutational defects which undoubtedly exist in these offspring. They may be evidenced only through slight changes in longevity, in minor dysfunctions of an organ or groups of cells, or may be completely undetectible by present methods. I am thoroughly convinced that the conclusions of Muller[5] from his works on hereditary damage produced by radiation of fruit flies are valid, that radiation induced mutations are nearly all detrimental, and that radiation produces a considerably greater mutational effect in man than in drosophila.

In order to determine whether a hazard exists, it is necessary to set a dose limit. For individuals working with ionizing radiation, this figure is now .3r/week. It has also been recommended that no one receive a gonadal dose exceeding 10 r, in addition to background, from conception to age thirty. Background radiation is that received from naturally radioactive substances, which are present everywhere, and from outer space in the form of cosmic rays. These are rather low figures and believed to be safe. Are these conservative limits being exceeded? I believe that in the majority of cases radiation is being held down to tolerable limits. There are abuses, however, which constitute hazards. They are well known to radiologists but less familiar to occasional users of x-radiation.

Among the more important abuses of x-rays is the non-indicated x-ray study—allow me to mention a few which I have encountered. First are studies requested by the patient—usually a patient covered by hospitalization insurance with an allowance for x-ray studies. The responsibility for this abuse, however, lies with the physician who acquiesces and orders the studies. Second are unwarranted studies requested by overzealous physicians. In this category may be listed multiple x-ray studies ordered en bloc; for example, stomach, colon, gallbladder and intravenous urogram. Frequently, such studies are ordered before simpler tests such as urinalysis or stool examination; and, I am ashamed to state, sometimes before a physical examination is done. Next example in this group is too frequent follow-up. It is foolish, pointless and hazardous, for instance, to x-ray a duodenal ulcer every two weeks. Further abuse in this connection is ordering x-ray studies before they are indicated, for example, after only a few days of stomach symptoms to rule out ulcer. Lastly, under abuses by over-zealous physicians, and probably most important, is exposure of children to multiple studies without adequate shielding of gonadal regions. Again in the class of non-indicated procedures may be mentioned x-ray studies made at the insistance of relatives. Along

the same line, in cases of litigation, an attorney will sometimes request complete x-ray studies. I do not believe it is within the province of a nurse to order x-ray studies, yet in many instances the doctor has not seen the patient before he is sent to the x-ray department. School nurses particularly seem to pre-empt this privilege.

One possible source of excessive x-radiation to both the patient and the operator is use of fluoroscopy. Frequently, it is done under less than ideal conditions—that is, before complete dark adaptation of the fluoroscopist's eyes has been attained. The use of too large fields radiates a large volume of the patient's body, and in older machines, may even allow the direct x-ray beam to reach the operator, unattenuated by the patient's body or the lead glass screen. Many of the older machines have inadequate lead protection about the tube and are devoid of aluminum filtration. Unless the operator knows for sure, that his machine has this protection he should check the presence and amount of filtration in his machine. It should have at least a 2 mm aluminum filter; 3mm is still better. These older machines also have a short target-table top distance, which increases the amount of radiation to the patient. Use of fluoroscopy to remove foreign bodies and to reduce fractures is extremely hazardous; it can only be condemned. Fluoroscopy in infants and children should be reduced to the absolute minimum. Unless the shutters are constantly kept to the smallest possible opening, large volumes of the body are irradiated, including the critical gonadal and bone marrow regions. Infant fluoroscopy is low in diagnostic yield. Tissue contrasts are poor. Technicians and nurses are required to hold the infants and they too get significant exposures.

Another source of excessive radiation is the portable x-ray machine. Many of the models in use today are limited in penetrating power; that is, in kilovoltage. They require excessively long exposures. Most have no diaphragming device and in many cases the cones are not used. The resulting film is low in diagnostic yield. The operator is seldom adequately protected. For these reasons it is better to move the patient to the x-ray department whenever possible.

Since we now know that x-rays are potentially dangerous both to the operator and to the patient, it behooves us as conscientious practitioners to do all in our power to minimize the dangers. A very practical manual on the *Medical and Dental Use of X-rays With Control of Radiation Hazards* recently came off the press. It was prepared by the American College of Radiology and written by Dr. Richard Chamberlain who addressed Minnesota State Medical Association in May, 1959. I can summarize in no better way than by reiterating the recommendations given in this manual.

Common sense is the best protection against radiation hazards. The benefits to be derived from increased accuracy of diagnosis greatly outweigh the dangers inherent in use of x-rays. Nevertheless, this method should be employed only after due consideration. Weigh the benefits against the risks. Have good and adequate indications for any x-ray procedure you order. Avoid "head-to-toe" examinations. Be especially cognizant of potential dangers to children. Know your x-ray machine, its filtration, the amount of radiation it produces. Use highest kilovoltage and lowest milliamperage applicable to any procedure. Use cones and shutters to keep the field of exposure as small as possible. Use lead rubber to protect the gonadal regions whenever possible.

Remember always that while x-rays are one of medicine's greatest boons they are not without danger. The danger cannot be directly seen. The peril to future generations cannot be disregarded. Responsibility for the health of millions of people yet unborn may be in our hands. It is a real and serious responsibility—guard it well.

The Organ of Sight

MALCOLM A. McCANNEL, M.D.
Minneapolis, Minnesota

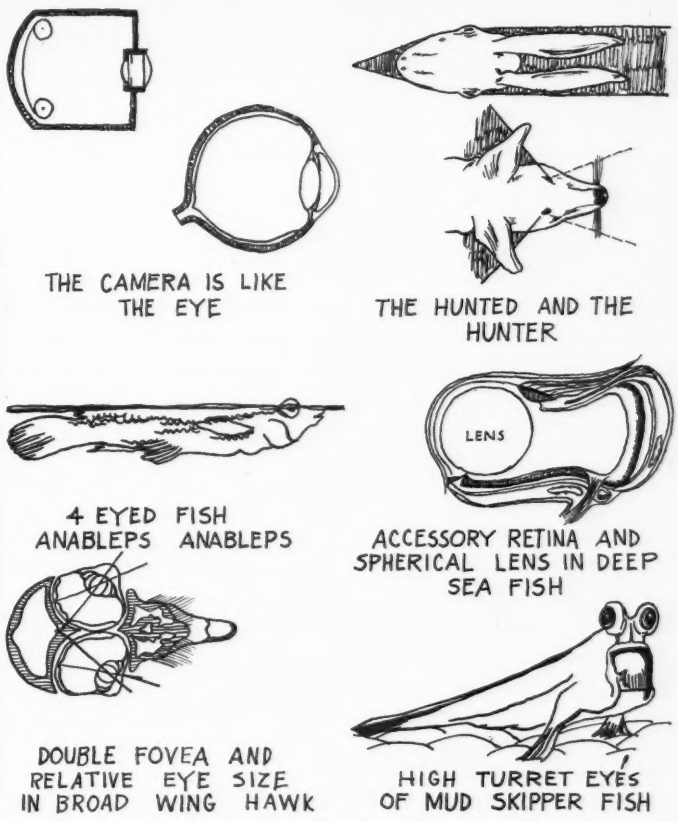

Fig. 1

Adapted from an inaugural thesis given before the Minneapolis Academy of Medicine.

THE SUBJECT of any inaugural thesis always poses a difficult problem to the specialist. He knows that he is to present his material before a group which comprises all of the specialties in the practice of medicine, and is constantly mindful, then, that his audience is a composite general practitioner.

For the sake of broader interest, material has been gleaned from pre-medical and ophthalmological text books and a review of some comparative anatomy pertinent to the eye and its form and function has been assembled.

In gathering ideas and material on this subject, so many ramifications, by-ways, and concepts were brought to the writer's attention that it was soon evident that only a few of the structural eye adaptations which seemed of interest could be presented, hoping to whet physicians' appetites to seek further information from the works of Walls, Detweiler, Prince, Wolfe, Wood, and others. It seems almost unbelievable to learn of the interest, time and tenacity shown by such a man as Casey Wood, whose famous work on the "Fundus Oculi of Birds" covers several hundred ophthalmoscopic examinations of our feathered friends in that one volume alone.

It is common knowledge among students of biology that vertebrate eyes are constructed along a common architectural plan. There are many fascinating deviations to be observed in this structure, but all of the functions—the light collecting, the bending and refracting of the rays, the sen-

sory mechanism in receiving, and the transmitting devices to the higher centers, are found in all vertebrate eyes.

General Structure and Extraocular Muscles

Consider, for a moment, the human eye and review some of its form and function with a few selected clinical applications. In a human, the eye is well protected by its bony orbit. The orbit has seven facial bones all locking together so the eyeball itself is recessed for protection. It is cushioned in its fat as well as in the extraocular muscles and is cradled there in a soft, yet firm, enough position to be protected while remaining mobile. The lids have tremendous musculature so that they can close quickly in the presence of danger. In order to keep the lids from being floppy pieces of skin and muscle, nature has constructed a connective tissue tarsus to give the lids some rigidity and form an attachment for the levator muscle. The two eyes are not only partially supported but are also rotated in a coordinated fashion in their orbits by the extraocular muscles. There are six attached to each eye. It is estimated that the ocular muscles alone are one hundred times more efficient and strong than they need be to rotate the eye. Ophthalmologists become very preoccupied with these muscles not only because the problem of strabisms affords them a good share of their bread and butter, but also because those eyes which respond to glasses, orthoptics, surgery, and similar measures provide a great satisfaction by correcting obvious cosmetic and functional defects.

Wetting Mechanisms

The lacrimal glands which secrete tears, and the ingenious collecting apparatus at the inner corner of the eyes which drains excess moisture down the nasal lacrimal duct into the nose, are useful in man, but the latter is absent in the elephant, fortunately for the veterinarian who might feel the need to perform dacryocystorhinostomy surgery.

The lacrimal gland provides a secretion which is a very good wetting agent, has a tremendous ability to annihilate micro-organisms, and tends to wash away any foreign material coming into contact with the eye. The amount and consistency of its flow is important as are the precipitating factors, whether the normal drip, drip, drip during the day or the increased amount precipitated by a speck of dust or the veritable waterfall that occurs with psychic doldrums.

Very little of the secretion formed during our waking hours ever spills down the cheek unless there is a ptosis or a relaxation of the tone of the periorbital muscles as occasionally seen in the elderly. Nature has even very thoughtfully provided oil glands in the tarsus and its border to increase the surface tension and prevent this spillage just as a housewife might put a little butter around the lip of the syrup pitcher so its contents won't run down the belly of the container and soil the tablecloth.

The Photography Simile

Remember, the eyeball is really composed of the segments of two spheres. The corneal-scleral coat is the tough sturdy outer covering and the first of three. Just inside the sclera is the uveal tract whose name comes from uva, the Greek word for grape which it resembles. Its three portions are the iris, ciliary body, and the choroid. The innermost coat is the retina which, even with its ten layers, is not much thicker than a sheet of cellophane; and the nerve fiber elements stream out the back of the eye to form the optic nerve.

It is an old cliché, of course, to say the eye is like a camera. The two do have a very striking resemblance. Each of them possesses a front and a rear lens. In the eye, the front lens is represented by the cornea and the posterior lens by the crystalline lens itself. Between these two lenses, whether in the eye or camera, a variable aperture is placed to control the amount of light which can enter. Both interiors are lined with black material to absorb light rays and to produce a light-free camera. In the eye, the black melanin pigment cells of the lining cause serious consequences when they go wild and form a malignant melenoma usually seen in the age group over forty. Mother nature can also play a wry trick by eliminating this pigment, resulting in attendant photophobia and blepharospasm which you have all seen in your albinic patients.

The camera is focused by mechanically moving the lenses toward or away from the light-sensitive photographic film. In the eyes, this distance is constant but the thickness of the crystalline lens is altered by the ciliary mechanism through a process we call accomodation. In the camera, the first steps in taking a picture depend upon the decomposition by light of a photosensitive

substance. This is usually silver bromide suspended in a colloidal gelatinous film. The eyes also depend upon decomposition of photosensitive substance in the visual receptors, and a photochemical break-down and resynthesis are constantly going on.

By recalling college physics, one remembers that a one diopter convex lens will bend parallel rays of light and bring them to a focus at one meter. The eyeball is approximately one inch in diameter and because of this short distance it requires roughly a sixty diopter lens system to bring parallel entering rays into a clear focus on the retina. The cornea itself is by far the strongest lens of two and accounts for about seventy-five per cent of the light ray bending necessary for this small camera. The crystalline lens accounts for approximately twenty-five per cent, or fifteen diopters.

The eye needs an even stronger lens system if the person looks at a close object, especially at the third of a meter necessary for reading the evening newspaper. The lens begins to lose its tremendous accommodative powers from the day human beings are born, but it is only when the middle forties come and the lens does not respond glibly and swiftly to the owner's demands for such mundane tasks as removing a sliver from the finger or reading the stock-market reports that it becomes necessary to provide an auxiliary lens in front of the eye. These spectacles may euphemistically be called reading glasses or the patient may submit to bifocals, the Benjamin Franklin invention of lenses split in two with distance vision above and the near glass below. All oculists grin inwardly when a very serious forty-five year old mother tells them that she is sure her youngster is hurting his eyes because he is holding printed material and coloring books so very close to the eyes and is reading and drawing at a four inch distance. This actually mirrors her concern over her own presbyopia which is starting to creep up on her as her near point is creeping away.

All oculists are extremely preoccupied with the crystalline lens, for if through disease, injury, or senescence it should become less transparent, its opacities block the entering light rays. It is inappropriate, here, to list all the misconceptions which are so prevalent in relation to this clinical entity called 'cataract.' To mention only one, a patient with a cataract will probably construe the reluctance of his oculist to perform cataract surgery as the necessary waiting time for it to become "ripe" as it used to be said. This is no longer true. A cataractous lens, any degree, can be removed at any time. The ophthalmologist is actually probably waiting until the other eye fails to the point which he deems necessary before doing a cararact extraction. For even if a cataractous lens is successfully removed and better than 20/20 vision is achieved, if its fellow eye has useful vision, the two eyes can never work as a team to give binocular or stereoscopic vision. This is due to the disparity of the size of their two images. If one of the eyes can still give useful service surgery is often deferred. The laity who misinterpret this hesitancy for surgery put it on a waiting to get "ripe" basis because this is easier to understand than an anisometropic aniseikonia.

The Eye in Other Animals

Let us consider the eye and its structural adaptations in some species other than Homo Sapiens. The animal world is divided into three main activity groups: those which are diurnal, or active in the daytime, those which are nocturnal, and those which are arhythmic, or active at all times and under all conditions. There is also the division between those animals that are primarily hunters, and those that are the hunted. The entire anatomy of the eye and the orbit of the eye is dependent to a certain extent on the animal's activities. If one understands this, one can assume a great deal about an animal's habits and inclinations by a study of its ocular anatomy. For example, many nocturnal animals possess extremely large corneas and huge lenses as if Mother Nature had decided that they should gather every possible illumination. Most animals have round pupils, and the nocturnal animals can get along with circular pupils if they stay out of bright light. However, slit pupils provide a smaller aperture and, as Detweiler says: "Any strongly nocturnal rod-rich animal which cares, or dares, to venture out in the sun—whether a cat stalking a barnyard sparrow, a Gecko seeking flies, a snake seeking warmth, or a shark basking at the surface—needs a slit pupil and will be found to have one."

It is a general rule that eyes which are well forward in the head and are more suitable for

concentration on hunting are accompanied by less prominent snouts. The shape of a rabbit's head and the position of its eyes are fairly typical of a hunted type of an animal. This position gives it a very peripheral type of view. In predatory animals, such as a fox or wolf, the eyes are well forward and concern themselves less with pursuit by other animals.

One of the most interesting eye adaptations is seen in the four-eyed fish called Anableps anableps. This minnow swims on the surface of quiet waters. The eye actually has two pupils, one for air vision and one for water vision. The water line cuts the eye in two. The lens in this eye is pear shaped and the curvatures of the dioptric system used for the submerged pupil are sharper than those employed in the superior or air pupil. Thus both aquatic and aerial views are focused simultaneously upon different regions of the retina. This might be called a genuine bifocal amphibious eye.

Some fishes are constantly submerged except for an occasional leap out of the water. The archer fish, or toxotes, is one that spies its prey outside the water, leaps out and shoots a projectile stream of water at an insect, knocking it down to the surface that it may be devoured. Walls in his book says "If the hydraulic artillery of the Archer fish is dependent upon what he can see from the surface below, he must have a truly remarkable trigonometric range finder in his brain to cope with the ever varying distortion of angles, sizes, and distances."

In some fish the eyes are vertical and in others the eyes are tubular and horizontal. Since their habitat is under water, a markedly spherical lens is maintained. The index of refraction of water and the cornea is approximately the same; thus, the contact of the water against the cornea nullifies the dioptric strength of the cornea, and the intraocular lens from necessity compensates by becoming more spherical and of much stronger dioptric power. In the eye of the Dissoma Anale, a deep sea fish, an accessory retina is found laterally in its vertical eye. This continues up the side and is quite close to the lens. It is felt that the two retinae allow focusing at both distance and near, which can be compared to the bifocals which we find necessary for presbyopia.

A change of the eye position from birth to maturity takes place in some fish. Broadly speaking, it can be said that this movement depends first upon the necessity to achieve survival and then later to perform specific tasks. In the flounder, for instance, there is an eye on each side of the head at birth, but as the flounder matures and turns on its side, the bottom eye migrates through a hole in the skull to assume a position with its fellow eye on the same side, the upward side.

Relative Eye Size

The size of the eye varies tremendously. Amphibians and reptiles have small eyes. Fishes and birds have large eyes. The size of the eye bulbs is relatively constant for members of the same species. There is no constant relationship between the body size and the eye size. Duke Elder points out that eye size seems to be correlated to a greater degree with the nimbleness of the animal's movements and the necessity for sharp vision than with body size. The eye of an antelope, for instance, is larger than that of an elephant. The eagle's eye is larger than man's and some hawks' eyes are equally large. Nocturnal animals and deep sea fishes have characteristically large eyes. A large sized eye holds more advantage for a bird than does an enclosed orbit. Since there is not room for both, nature has increased the strength of the eye by including bone and cartilage in the anterior portion of the hawk's, as well as the owl's sclera, to mention two. Also the eyes in these two examples occupy about one-third the size of the whole head.

In man, the fibrous tunic, or outer layer of cornea and sclera, is made of dense connective tissue. In fish, this layer becomes hyaline cartilage and in some of the reptiles and birds, the cartilage or scleral ossicles are all continuous around the eye to give it support. On the coast of Asia, West Africa and Polynesia, is seen an interesting fish called the mud skipper or Periophthalmus. Its eyes are built in high turrets and swival around as if on universal joints. The eye actually revolves under a secondary covering which protects the cornea from drying out when exposed to air.

Protective Membrane

The nictitating membrane is found in some birds and amphibians; it is a "third eyelid" and is derived from the conjunctiva. Ovio states that this membrane is less developed as the animal's paw is more able to wipe the eye. All that re-

truly repository injectable B_{12} quickly achieves and sustains high B_{12} blood levels for a minimum of 28 days

The Depinar special repository base permits slow absorption from the injection site, thus decreasing the need for frequent administration. Depinar continually bathes the tissues in vitamin B_{12} to provide more effective therapy and make patients feel better longer. A recent clinical report* shows over 98% of Depinar is retained after one week . . . and "Serum level vitamin B_{12} . . . sustained for 28 days or more from the single dose."

Each package of Depinar consists of a multiple dose vial, containing cyanocobalamin zinc tannate (lyophilized) equivalent to 2500 mcg. vitamin B_{12}. The vial of diluent contains 5 cc. Sodium Chloride Solution for Injection. When reconstituted, each ml. of Depinar contains 500 mcg. vitamin B_{12}.

ARMOUR

(Continued from page 1786)

mains in man is the semi-lunar fold of the eye. In birds and some amphibians the nictitating membrane as it is stretched over the eye becomes more transparent in the center and thus forms a sort of window. The tendon of the nictitating membrane passes behind the eye bulb for a better purchase. Birds seem to use the nictitating membrane to the best advantage because, although difficult to verify, it is thought that they keep their eyes covered with it during flight because dehydration of the cornea would result with the prolonged and rapid passage of air over the eye.

When a group of animals changes a way of life, as for instance to burrow below the ground, a delicate cornea would be subject to all kinds of injuries from the abrasive action of the grit and sand. A most effective defense is the spectacle or "brille" which is a thickened transparent membrane over the cornea. Eyelids are a natural defense but some animals have kept them closed for so long, because of living below ground, that the eyes have degenerated to the point of uselessness. An example of a true burrower is the mole which has an eye, less than two millimeters in diameter, which is considered almost totally blind.

Lens and Aperture

Lenses in all vertebrate eyes have a common origin in that they are derived from the invaginated lens plate from the surface epithelium or ectoderm. As one ascends the evolutionary scale, the lens becomes less spherical and more biconvex. In some animals such as the nocturnal Gecko, or nocturnal lemur, the Galago, the lens is also quite spherical. In this case, the lens is so enormous that it is almost equal to one-third of the vitreous cavity. In the human it is about one-ninth the size of the vitreous cavity.

The aperture, or pupil opening, in the front of the eyes varies greatly with different species. So great is the individual variation of the structure and configuration of the iris in humans, that it was long ago suggested by Bertillon, the criminologist, that it be used as a basis for criminal identification. Recently the theory has been revived. Among the more imaginative obstetricians, literature has been published which attributes to the knowing practitioner an ability to predict the sex of an unborn child by a biomicroscopic examination of the pregnant mother's irises. This work, to my knowledge, has never been confirmed.

The ability to make a pin point aperture provides a great capacity to form sharp images at great distances by the phenomenal pin hole principle. I know of only one animal which has a lensless eye and a pin hole camera type vision. This is the nautilus, a spiral-shelled mollusk. This eye has the advantage of being in focus at varying distances from the object being viewed. This principle can be put to use by any of one's myopic friends who accidently drop their glasses on the bathroom floor. One can take a conventional calling card and cut it to fit the spectacle frame. Punch multiple pin holes in the card and the patient will be able to get around with it until a new lens is made.

The Light-Sensitive Retina

There is probably no other portion of the vertebrate eye that has undergone as many changes and adaptations as has the retina. The foregoing describes how the pupil controls the amount of light in the eye. There is another mechanism that exists for adjusting the eye to changing illumination.

Over a hundred years ago, the discovery was made that in the retina there are two main types of visual photoreceptors or cells. These are called rods and cones, each serving a different function of vision. The rods are so-called because of their form and are primarily concerned with colorless vision at low intensity of light and are so situated in the retina that they subserve moving and peripheral, or tail of the eye vision. This is called scotopic vision. On the other hand, the cones are concerned with color, form, and vision at an increased intensity of light. This is called photoptic vision. This concept is called the duplicity theory of von Kries. In the human eye, there are approximately seven million cones and more than one hundred million rods. The rod-cone ratio varies when you pass from the center of the retina in the macular area where there are primarily cones to the periphery where the cones are quite sparse or absent and the rods predominate.

In some animals, photochemical change occurs in the retina so that in bright light the cones contract and the rods elongate. At the same time, the epithelial pigment migrates down over the rods' outer segments to shield them, as it were, from a strong light. With the cones thus being

made accessible to the strong light present, this is the best possible condition for vision. The reverse is true in dim light or nocturnal vision. Here the cones elongate and the rods contract and the pigment contracts back towards the body of the cell. In this diminished light, the rods have become available for the weak light and the cones have moved out of the way. In man, the rods and the cones do not contract, but he does have migration of pigment called dark adaptation of the retina.

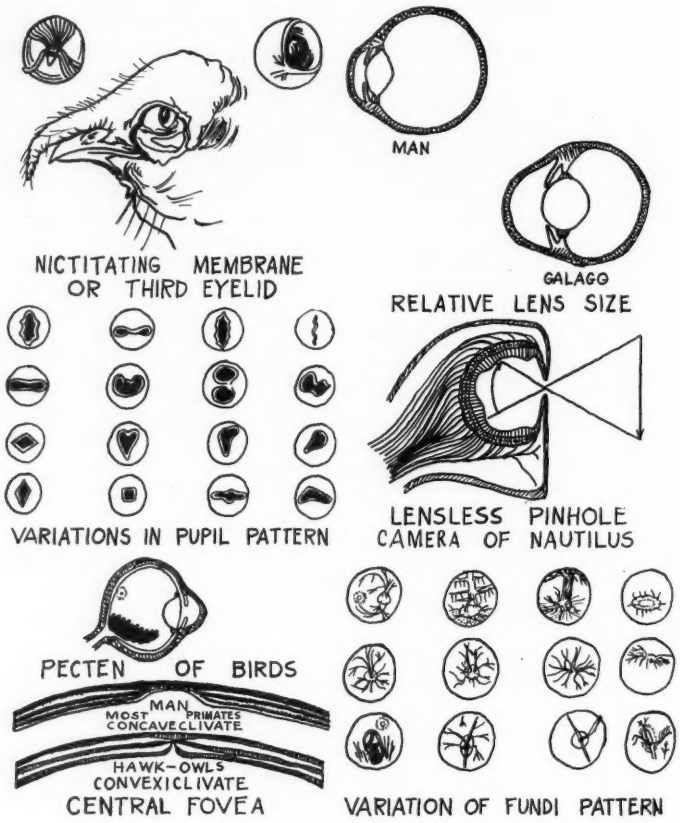

Fig. 2

Some Variable Structures in the Fundi

An ophthalmoscopic view of the fundus can vary tremendously from species to species. Great variations can be found not only in the position and shape of the disc but also in the disposition of nerve fibers in the vessels and fundus. In a bird's eye for instance, you will always find a pecten. This is a pleated triangular membrane that extends into the vitreous chamber usually near the optic disc. It is richly supplied by blood vessels and is folded and convoluted as it extends forward from the nerve head. It is completely covered with pigment which gives it a velvety appearance. Many theories have been expounded on its use. One is that it helps the bird in its celestial navigation; another is that it helps nourish the eye because of the cone-rich retina; another, that it is a protection of the eye against intense light because the rich blood supply can help carry away the heat of the sun at high altitudes.

Several devices noted above have been used in the animal world, to improve vision at night. One which has not been mentioned is called the "tapetum." This is a layer of reflecting tissue of metallic crystals behind the retina. This produces "eye

shine," the reflection seen coming from the eyes of animals when the headlights of an automobile flash on them. The reflecting tapetum is never seen inferiorly to the horizontal equator of the eye. If it were present below, it would catch all of the glare from the sky and would cause a dazzle in the animal's vision. The tapetum is usually responsible for the color of the animal's eyes. Red color in the fundus is seen in primates, including man, and the color comes from the blood in the choroid modified by the density of the pigment of the epithelium. A yellow color is usually seen in cats, elephants, and squirrels. There is an enormous variation in the ophthalmoscopic patterns, and if one really wishes to be startled, he should take an ophthalmoscope and look into the fundus of a horse.

The Point of Focus

And finally we shall discuss, for a moment, the fovea. In photography, a fine-grained emulsion film takes a much sharper picture than a coarse-grained emulsion. Such a situation is felt to exist in the fovea. In the macular areas, there is a great variation in the concentration of the number of cones in any given space. One researcher felt there were approximately one million cones per square millimeter at the fovea of the hawk, Buteo, compared with man's fovea which is estimated to have about one hundred and sixty thousand per square millimeter. This disparity alone would convince one that a hawk's vision is much sharper than man's. It is felt by conservative researchers that the resolving power of visual acuity in some hawks and eagles is approximately eight times that of humans. The depression, or thinning of the retina at the foveal area has usually been thought to be constructed so that light may have unimpeded access to the visual cells without passing through the various layers of the retina as it does elsewhere. In this connection, Walls, in 1942, offered a very stimulating theory based on the difference in refractive indices of the vitreous and retina. Walls felt that when light struck the foveal clivus, or depression, it was refracted and broadened its image by bringing into play a larger number of visual cells than would otherwise be utilized. The convexiclivate fovea is seen in those creatures which we readily admit have vision that is far superior to our own. In man's concaveclivate fovea, because of its broader base, the refractive index of the clivus is not so great. Some animals have two foveas. In birds, there is often a foviate band which is called a strip fovea. This sometimes joins the temporal and central foveas and is usually found in the more predatory birds and the faster flyers.

Conclusion

This presentation is concerned with only a part of the structural adaptations of the eye. It is self-evident that in the general scheme of evolutionary ascendency, the human eye does not represent the acme of efficiency as far as an organ of sight is concerned. One notes that birds are equipped with a much more efficient focusing apparatus and a more complex macula subserving higher visual acuity than is man. However, *Homo sapiens* can draw himself up with customary superiority and loudly declare that these other animals do not possess his Betz cells and cortical connections which provide such reasoned visual judgments and interpretations, and that with this superiority of the visual brain cortex over animals, one can help keep and hold the intellectual supremacy of man.

Endometriosis of the Sciatic Nerve Without Evidence of Pelvic Endometriosis

Report of a Case

Read at the meeting of the Southern Minnesota Medical Association, Rochester, Minnesota, September 14, 1959.

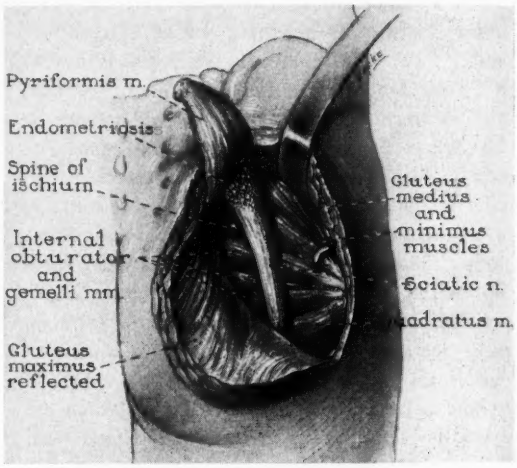

Fig. 1. The operative approach and the lesion of the endometrium in the sciatic notch with the piriformis muscle reflected.

● *Cyclical pain occurring anywhere near the pelvis and having the same rhythmicity as menstruation should suggest the possibility of endometriosis. In this case, endometriosis involved the sciatic nerve in the absence of any other evidence of ectopic endometrium. The pain was controlled by establishing an artificial menopause.*

The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

SINCE the work of Mixter and Barr[1] in 1934 on rupture of the intervertebral disk in the lumbar region as a cause of sciatica, and later papers by Love, Camp[2] and others[3] demonstrating this clinical entity, there has been a growing tendency on the part of physicians to consider rupture or protrusion of an intervertebral disk in the lumbar region as the only cause of sciatic pain. This has occurred in spite of papers by Bankart,[4] Young[5,6] and others emphasizing the other causes of sciatic pain. Among the other causes are spinal arthritis, neoplasms of the soft pelvis and the pelvic bones, infections and other diseases of the sacro-iliac joints, osteoarthritis of the hip, peripheral neuritis, osteoid osteoma or eosinophilic granuloma of the femur or pelvic bones, soft-tissue tumors of the popliteal space, fractures of the vertebrae, and myositis or bursitis in the gluteal region. Tumors of the sciatic nerve itself may produce sciatic pain also.

We wish to report in this paper an unusual case of endometriosis involving the sciatic nerve and producing sciatic pain. The cyclical nature of the pain and the difficulty in establishing a diagnosis were important features of the clinical course. In addition, we wish to present the pathologic features and a theory on the possible pathogenesis of this condition.

Only a few cases of endometriosis associated with sciatic pain have been reported. Caprioglio[7] reported the case of a woman with supposed pelvic endometriosis who had sciatica, but no operative procedures were carried out. Dagnelie[8] reported in detail a case of sciatica of cyclical nature in

which he was able to palpate nodules on the sciatic nerve in the pelvis. His patient was relieved of symptoms by testosterone, but no exploratory operation was carried out. Schlicke[9] reported another case of sciatica in which a painful nodule in the posterior part of the thigh proved to be an endometrioma on biopsy. Ectopic endometrial tissue in the area of the sacrococcygeal junction was reported to be a cause of sciatica by Amaral Ferreira.[10] The many other reports of ectopic endometrial tissue in the literature will not be reviewed in this report.

Denton and Sherrill[11] reported the only case of endometriosis involving the sciatic nerve itself that was proved by biopsy so far as we could determine. Their patient, a forty-eight-year-old white woman, had had recurrent right-sided sciatica for three years; the attacks would begin two to three days prior to her menses and subside two to three days after cessation of menses. Physical findings included hypalgesia in the distribution of the first sacral nerve root with a positive result from the straight-leg raising test and tenderness over the sciatic notch. A myelogram revealed protrusion of the fourth lumbar intervertebral disk on the right side. However, they did not perform laminectomy, but explored the sciatic nerve and found a 2-inch tumor involving the lateral quarter of the nerve just above the greater trochanter. In this case, as in ours, the endometrioma of the sciatic nerve appeared to be a solitary lesion and was not accompanied by other lesions of endometriosis in the pelvis or elsewhere.

Report of Case

A thirty-two-year-old married woman, gravida 4, para 2, first registered at the Mayo Clinic in September 1957, because of low back pain and pain in the posterior portion of the right thigh of two years' duration. The pain typically began two to three days prior to her menses and lasted two to three weeks. There was only a seven- to ten-day pain-free interval between menses. Her gynecologic history was normal. There were no menstrual irregularities, and her general health and a review of systems were noncontributory.

Examination revealed a woman of medium stature who was apparently in good health. Except for moderate hypertension the only other positive physical finding was limitation of motion during the straight-leg raising test on the right side to 45 degrees. Laboratory findings were within normal limits. Roentgenograms of the lumbar vertebrae revealed a transitional lumbosacral segment and four normal lumbar vertebrae. Because the patient had a history of sensitivity to iodides, an air myelogram was made. The results of this were equivocal, although some deformity of the air column at the lumbosacral level on the left seemed likely. A tentative diagnosis of protruded intervertebral disk was made, and the patient was instructed in conservative measures.

She returned in March 1958, reporting much the same history of cyclical pain of increasing severity. Results of the general examination were the same as previously, but neurologic examination revealed definite weakness in the anterior tibial, toe-extensor, and peroneal muscles. The straight-leg raising test on the right showed limitation of motion at 30 degrees. Reflexes were normal. An electromyographic study revealed fibrillation, grade 3, on a grading basis of 1 to 4, in the anterior tibial, toe-extensor and peroneal muscles. This was interpreted as indicative of denervation of the muscles supplied by the fifth lumbar nerve root. Gynecologic examination which had been negative previously was repeated because of the possibility of endometriosis, but no abnormalities were found.

On March 25, 1958, an exploratory hemilaminectomy was carried out at the fourth and fifth lumbar interspaces on the right side. At the fourth lumbar interspace a degenerated protruded disk was found and removed. The surgeon reported that the nerve root appeared to be tightly compressed prior to the removal of the disk and was loose after the disk was removed. A protruded disk lying laterally at the fifth lumbar interspace on the right side was removed also. Because of the congenital anomaly of the lumbar vertebrae, an iliac fusion was carried out extending from the fourth lumbar to the second sacral segment on both sides. Postoperative convalescence was complicated by a staphylococcic pneumonitis which responded promptly to antibiotics.

The patient returned home without being relieved of symptoms. By August 1958, five months after operation, however, she said that she was nearly free of her symptoms, and the fusion was found to be successful.

The patient again returned to the clinic in February 1959, with recurrent pain which was identical to that which she had had prior to operation. The symptoms were somewhat more severe and examination disclosed that the right hip was held in abduction and external rotation. There was obvious atrophy of the hamstring and sural muscles as well as those in the anterior aspect of the leg. She stood with a list to the right side at the lumbosacral junction, and there was spasm of the erector spinae muscles. A high degree of tenderness was found at the sciatic notch.

On February 19, 1959, a diagnostic paravertebral block at the fifth lumbar level on the right side with lidocaine hydrochloride (xylocaine) was performed. This did not relieve her pain, and the procedure was discontinued because of rather severe bleeding. At this time exploration of the sciatic nerve was decided on because of the aggravation of the pain on internal rotation of the hip and the definite tenderness at the sciatic notch.

On March 12, 1959 (Fig. 1), the sciatic nerve was approached through a modified Gibson incision, and at the level of the sciatic notch the nerve was found to be encased and infiltrated by a dense, brown, fibrous process for a distance of about 1.5 inches that extended

into the adjacent surrounding tissue at the sciatic notch. Decompression and neurolysis were carried out, and specimens of the tissue and of the nerve sheath were removed. A small incision into the posterior part of the capsule of the hip revealed no abnormalities of the hip joint itself. The piriformis muscle was sectioned at the time of operation.

Following the operation the patient remained free of pain until the fourth day of her next menstrual period when the pain recurred and was present for approximately ten days. It then began to subside. Examination at that time revealed poor function of the peroneal division of the sciatic nerve. The pathologic report had revealed an endometrioma involving the sciatic nerve, so that the patient was offered irradiation to suppress ovarian function. This was accomplished by roentgen therapy over the pelvis. The patient has had no pain since that time. The motor function of the peroneal division of the sciatic nerve has not recovered to date.

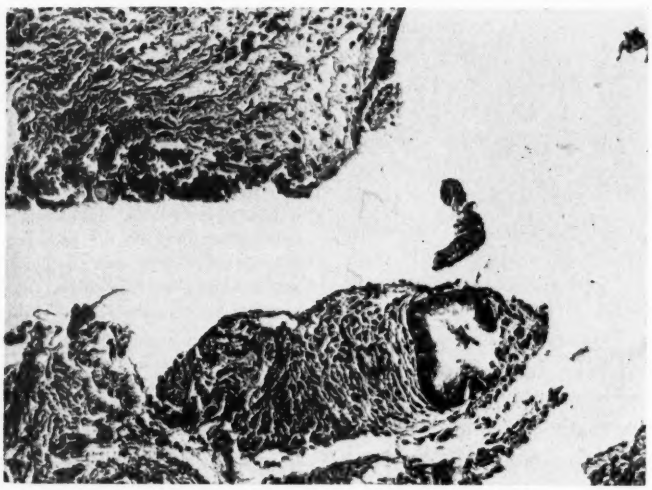

Fig. 2. Endometrioma of the sciatic nerve showing a typical endometrial gland surrounded by spindle and stellate stromal cells (hematoxylin and eosin; x150).

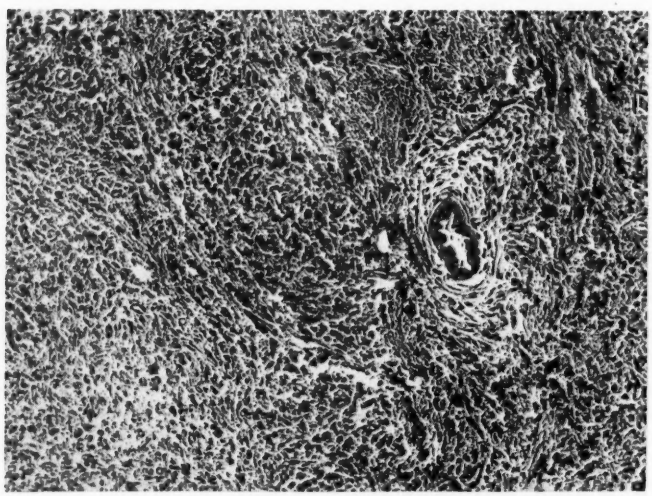

Fig. 3. An endometrial gland with its surrounding stroma appears in a mass of fibrous tissue which is richly impregnated with granules of hemosiderin deposited during ancient and repeated menstrual bleedings (hematoxylin and eosin; x150).

Pathologic Aspects.—The tissue removed at operation consisted of irregular fragments aggregating approximately 3 cm. in diameter. Grossly tough and fibrous, they were streaked here and there with dark-brown and

light-yellow zones of pigmentation. Microscopically, the bulk of the material exhibited fibrous-tissue proliferation with sizable aggregates of lymphocytes which were particularly related to the vicinity of the small blood vessels. Much of the tissue was impregnated with granules of hemosiderin which varied in color from light orange to dark brown in the hematoxylin and eosin preparations. Some of these granules were located within the cytoplasm of phagocytic histiocytes; others appeared to be lying free among reactive connective-tissue cells and the collagen fibers. A certain amount of hyalinization in these zones indicated a prolonged tissue reaction to repeated depositions of the pigment.

Scattered here and there, and illustrated in Figures 2 and 3, were endometrial glands lined by tall cells and surrounded by dark-staining, plump spindle cells which are characteristic of endometrial stroma. The combined picture was that of endometriosis with a tissue reaction from recurrent menstruation with dissection of tissues by menstrual blood and the products of glandular secretion.

Comment

From the previous recital of the facts of this case it is obvious that the diagnosis was difficult to establish, and we were misled by the presence of multiple protruded intervertebral disks and the relief of symptoms of this patient following removal of these disks and the successful fusion of the two lumbar joints. Although endometriosis was suspected as being the cause of this condition throughout our observation of this patient, repeated pelvic examinations failed to reveal any evidence of pelvic endometriosis. Because of this fact, speculation on the possible pathogenesis of ectopic endometrial tissue in the sciatic nerve seemed inevitable. Although the pathogenesis of uterine adenomyoma is related to direct invasion of the uterine wall by the glands and stroma of the adjacent endometrium, such an explanation cannot apply to the situation found in the case we are reporting. Likewise inapplicable is the implantation theory which might explain, by tubal regurgitation of endometrium, the familiar chocolate cysts of the ovaries and the peritoneal seeding of the cul-de-sac. Lymphatic embolization seems unlikely inasmuch as retrograde flow would have to be postulated to explain the carriage of endometrial tissue from the pelvis to the thigh. Metastasis via the blood stream always remains as an unprovable histogenetic possibility but, in our opinion, a remote one since among other things it postulates passage of the endometrial tissue through the lungs.

To us the most logical explanation for the occurrence of endometriosis of the sciatic nerve is metaplasia from the pelvic peritoneal mesoderm. It has been observed, for instance, that endometrial deposits in pelvic lymph nodes are subcapsular rather than more deeply placed. Current opinion accordingly discounts the notion that lymphatic embolism produced them and promotes the notion that they arose from the adjacent peritoneum by a process of metaplasia. By the same token, origin of the lower limb buds from the mesoderm adjacent to the pelvic peritoneum could account for the origin of such endometrial foci therein. The growth of the limbs then could effect the migration of such foci to the sites indicated.

The observed clinical phenomena of periodic pain and swelling relate to the fact that endometrial tissue, wherever located, responds with proliferation, differentiation, decidual reactions and menstruation to the action of ovarian hormones.

In conclusion, we have presented one case of endometrioma of the sciatic nerve without evidence of pelvic endometriosis that produced a picture of sciatic pain of a cyclical nature. The diagnosis was delayed because of the absence of pelvic endometriosis and the finding of multiple protruded intervertebral disks in the lumbar region. The only similar case which we could find in the literature, and one which parallels our case quite well, is one reported by Denton and Sherrill.[11]

Traumatic Interventricular Septal Defect

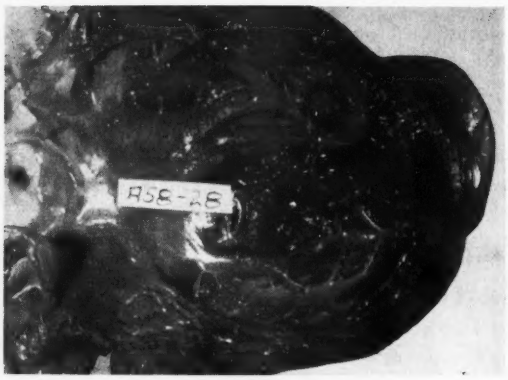

Fig. 1. Septal defect seen from the left ventricular side. The edges of the defect are smooth.

● *Evidence of external trauma to the chest need not be present with serious trauma resultant in the heart. This interesting case report of a healthy young man demonstrates the rare situation of an interventricular septal rupture in an apparently normal heart subsequent to an automobile accident. The availability of surgical procedures to correct such traumatically-induced defects as interventricular septal defects, aneurysms of the ventricular wall, and lacerations of the mural portions of chambers increases the necessity of accurate evaluation and diagnosis of these sequelae.*

WITH increasing automobile travel, the incidence of traumatic injuries is constantly rising and the heart is frequently involved by non-penetrating blows to the chest. In most cases such cardiac injuries consist of contusions or lacerations of the mural portions of the chambers. Interventricular septal damage is uncommon and is usually associated with much more severe damage in other portions of the heart. Cases of septal rupture in hearts normal before the trauma and without other cardiac injuries are rare. However, their recognition is important since surgical techniques have now been developed to correct these defects.

Pollock,[1] in 1952, reviewed the world literature and found twelve cases of isolated septal rupture to which he added another. All of these, and a fourteenth case reported by Cary,[2] were proved by autopsy. Guilfoil[3] recorded the first case established by cardiac catheterization in 1953. Two other cases proved by this means have been reported by Crow and Brogdon.[4] Successful repair of two such defects has been accomplished, one by Varco and Lillehei,[5] and the other by Pierce.[2]

The following case is reported to alert physicians once more to the possibility of cardiac damage when the chest shows no evidence of trauma and to present the pathologic findings in this unusual condition.

RILEY D. WOODSON, M.D.
Minneapolis, Minnesota

From the Department of Pathology, Minneapolis General Hospital, Minneapolis, Minnesota.

Fig. 2. Defect as visualized in cut surface through the interventricular septum. The linear character of the laceration is evident.

Report of Case

H. R., a twenty-eight-year-old ex-Air Force flight engineer, while driving his automobile late at night, fell asleep and struck a lamp post at a speed estimated to be greater than 50 miles per hour. He had been in good health prior to the accident, and a physical examination less than one year prior to admission indicated no cardiac abnormality.

On admission to the hospital he was in obvious shock, bleeding severely from a laceration of the neck and tongue. The pupils were equal and dilated, reacting to light and accommodation. The chest revealed no evidence of trauma externally, and no rib fractures could be palpated. The lungs were clear to percussion and auscultation. The left heart border could be percussed 9 cm. to the left of the midsternal line; the right border was at the midsternal line. A grade 4 crescendo systolic murmur was heard at the left fourth intercostal space adjacent to the sternum and was quite well localized to an area having a circumference of 10 cm. The murmur was barely audible at the base of the heart, could not be heard at the apex, and did not radiate to the back. No thrill was felt. A2 was reported as louder than P2. The rhythm was regular but over 120 per minute. The abdominal examination was negative. Examination of the extremities revealed fractures of the proximal one-third of the right femur, a compound fracture of the right tibia, a fracture of the right patella, and a bimalleolar fracture of the right ankle. Initial x-ray examinations revealed the lung fields to be clear, the heart of normal size, and no rib fractures. An electrocardiogram revealed a sinus tachycardia with left axis deviation. The PR interval was 0.14 to 0.16 seconds. T was flat in leads 1 and negative in AVR and AVL.

The patient was transfused, taken to the operating room, and the compound fracture of the tibia irrigated and reduced. He was returned to the ward in relatively good condition. However, within twenty-four hours he developed severe respiratory distress due to the accumulation of viscid secretions which necessitated an emergency tracheotomy. At this time his state of consciousness was noted to have changed markedly. He became confused and within five hours markedly somnolent; within ten hours he was comatose. Forty-eight hours after his admission, moist rales were noted diffusely over both lung fields. The cardiac murmur remained unchanged and the heart rate continued to be rapid. The clinical impression at this time was left heart failure and the patient was digitalized rapidly with cedilanid. Within six hours after completion of digitalization the rales cleared, the respiratory rate had dropped to 16 per minute and his state of consciousness improved.

On the third day many small petechiae were noted on the neck and trunk. Somnolence returned and the ventillatory drive was markedly diminished with respirations shallow and irregular. A surface skim of urine revealed many fat droplets. During the next three days the patient showed varying degrees of consciousness. The cardiac findings remained unchanged. The heart size by x-ray also remained unchanged but the lungs showed diffuse congestive changes and the liver enlarged to 5 cm. below the costal margin. Urinalyses, electrolyte balance studies, and hematological tests were maintained at normal values but the serum bilirubin rose to 3.3 mg. per cent. Other liver function studies gave normal values. The patient was maintained on daily injections of intravenous digitoxin. Blood and intravenous fluids were given as needed. Oxygen was administered under pressure on several occasions. By the seventh day the patient was being intermittently assisted with the Bird respirator because of continuing respiratory deficiency felt to be related to central nervous system damage from the fat emboli. There seemed to be gradual improvement during the eighth and ninth days of hospitalization, but

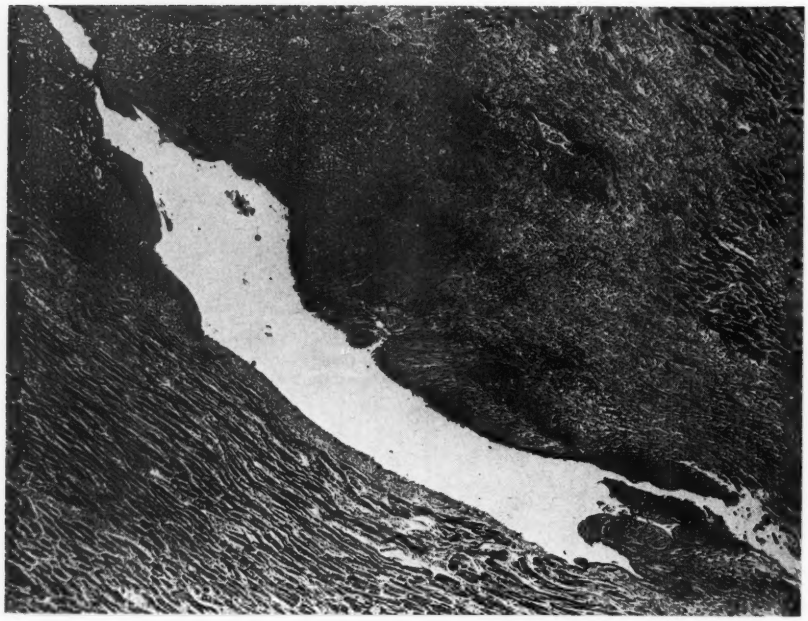

Fig. 3. The defect is parallel to direction of fibers. Portions of attached thrombus are evident (x30).

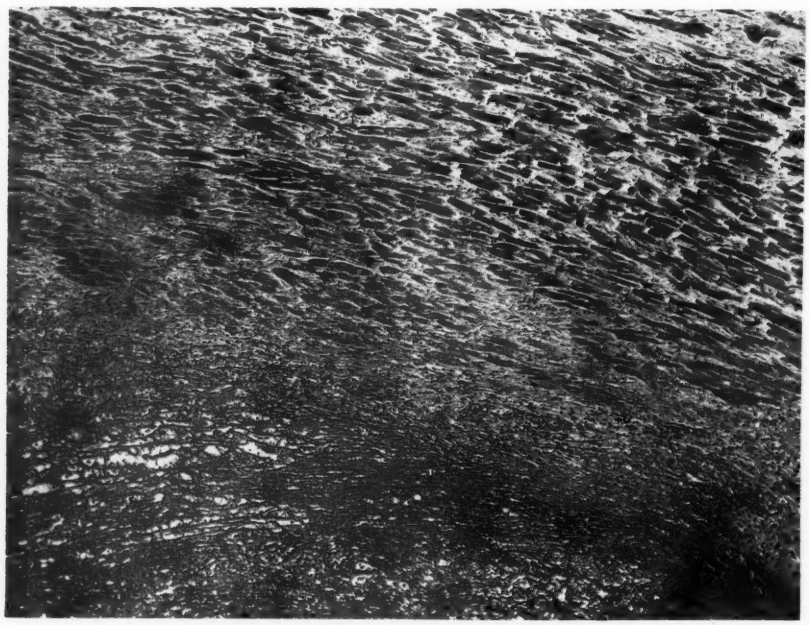

Fig. 4. Beginning organization of the attached thrombus is evident (x90).

on the morning of the tenth day the patient became ashen, a pulsus alternans suddenly developed, and within two minutes he expired.

Autopsy.—The postmortem examination was conducted approximately eleven hours after death. The external examination revealed scattered traumatic injuries of the head, neck, and extremities with a Kirschner wire in the right lower leg. The peritoneal, pleural, and pericardial cavities were free of excess fluid or adhesions. The heart weighed 410 grams. The epicardial surface was smooth and glistening. The ventricles did not appear hypertrophied. On opening the heart, both atria and their appendages were normal. The endocardial surfaces of both right and left ventricles were smooth and glistening. There was no evidence of performation or contusion of the mural surfaces of the ventricles. All valve leaflets were thin and pliable with no traumatic damage to the leaflets or chordae tendineae. The valve ring circumferences were within normal limits. Upon examination of the interventricular septum, a 2.4 cm. linear tear was found perpendicular to the caudocephalic axis of the heart which extended completely through the septum. This lesion was approximately midway between anterior and posterior wall and at the junction of middle and lower third (Figs. 1 and 2). Enmeshed in the rent was antemortem clot, and in one area of the free margin of the rent a thin rim of fibrosis was noted. Both coronary arteries were normal.

The lungs were diffusely nodular with purulent material in the nodules. The spleen weighed 500 gm. and appeared congested. The liver weighed 2300 gm. showing a nutmeg surface on section. The kidneys were swollen bilaterally with a combined weight of 380 gm. and also appeared congested. The brain showed scattered small petechial hemorrhages through the deep white matter, corpus callosum, the brain stem, and the cerebellar peduncles. With the exception of the fractures, the rest of the gross examination was within normal limits.

Microscopic examination of the tissues revealed passive congestion of the liver, spleen, and kidneys. The lungs showed patchy areas of bronchopneumonia. Special stains revealed fat emboli in the glomerular and cerebral capillaries.

In the heart, the interventricular septal defect was noted to be parallel to the direction of the main bundles of muscle fibers. There was antemortem thrombus adherent to the edge of the tear which showed beginning organization (Figs. 3 and 4). Sections away from the defect were entirely normal.

Discussion

At the beginning of isometric contraction, the interventricular pressure rises precipitously while the septum begins rotating about itself in a caudocephalic axis. If at this juncture a blow is sustained, one can postulate that since the tension is greatest in the I-V septum, it is this portion of the musculature which will rupture. One would expect the force to separate rather than fragment the myocytes, and the photomicrographs demonstrate the linear nature of the lesion with the sheer in the axis of the fibers and perpendicular to the caudocephalis axis of the heart. This corresponds with the majority of cases adequately described for comparison which have so far been reported.

Gore[6] has emphasized the need of caution in classifying lesions of the heart as traumatic in origin pointing out that even in young individuals pretraumatic disease may exist in the heart. We feel this case to represent solely a traumatic lesion since the previous history was negative and the pathologic findings, both gross and microscopic, are consistent with a lesion of approximately ten days' duration. The myocardium away from the septal defect shows no evidence of antemortem pathology.

The high incidence of trauma to the heart in automobile accidents has been discussed in many articles but the majority of such cases show injury of the chest wall as well. This case dramatically illustrates the severe traumatic cardiac lesions that can develop in the absence of any evident trauma to the thorax.

Summary

The pathology in a rare case of traumatic interventricular septal defect is presented which illustrates the severe cardiac pathology that may occur with no evidence of thoracic injury.

Auto-immunity in Thyroid Diseases

The author reviews the literature on auto-immunity in thyroid disease. He points out that there are two different antigens stimulating antibody formation in thyroid disease and suggests that there may be more. It is possible that spontaneous myxedema may be the end result of auto-immunity and thyroiditis. A correlation between chronic liver disease in women and thyroiditis-like alterations in their thyroids leads the author to suggest that there may be a pathogenic similarity here.

HORROR AUTOTOXICUS was the term Ehrlich used to describe what he considered a biological law—the inability to produce antibodies against the tissues of one's own body. For many years this concept was immunologic gospel, though reports appeared from time to time raising doubts about its validity. In recent years however evidence has accumulated for the existence of auto-antibodies in certain diseases. A prominent example is auto-immune hemolytic anemia.

The present interest in auto-immunity and thyroid disease stems from two approaches to the search for auto-antibodies in thyroiditis, both developing within the past four years. One reflects the work of Witebsky, Rose and co-workers in Buffalo, who were interested in antibodies to thyroglobulin produced in the rabbit. The other reflects the efforts of Roitt and Doniach to demonstrate that the elevated serum gamma globulins observed in Hashimoto's thyroiditis was due to increased circulating antibodies to thyroglobulin.

Long before these two groups sparked the present surge of interest in thyroid antibodies, a flicker or two of light on the subject was seen, but not pursued.

As early as 1908, Marinesco demonstrated a positive complement-fixation reaction between aqueous extracts of thyrotoxic thyroid gland and the serum of the patients from whom the glands were taken. His student, Papazolu,[1] extended these observations in 1911, observing complete or almost complete complement fixation with thyrotoxic gland extracts in twenty-six of thirty-eight

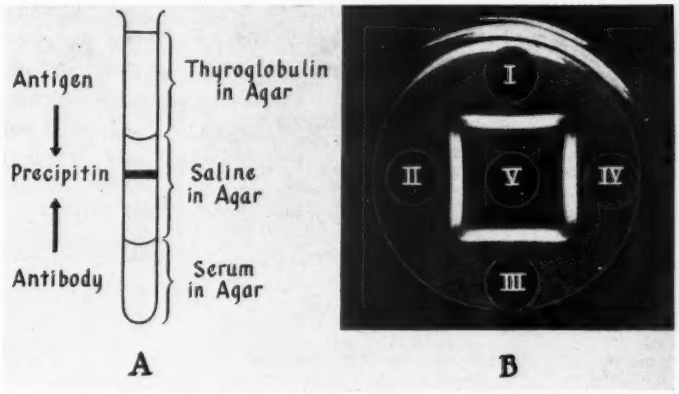

Fig. 5. A. Diagram of thyroglobulin precipitin test by a modified Oudin technique. Antigen and antibody diffuse toward each other through the saline zone, forming a precipitate when they meet in suitable proportions. (From Roitt and Doniach, Proc. Roy. Soc. Med., 50:958, 1957.)

B. Identification of thyroglobulin as the active antigen in the saline extract of thyroid using the diffusion-precipitation technique of Ouchterlony in agar gel. The five wells in the agar plate were filled as follows: I, Thyroglobulin, purified (5 mg./ml.). II, Thyroid extract (1:10). III, Thyroglobulin, purified (10 mg./ml.). IV, Thyroid extract (1:20). V, Hashimoto serum. The precipitation lines resulting from union of antigen and antibody after diffusion through the agar form a square. The confluence of the precipitation lines at the corners shows the identity of the antigens in the crude thyroid extract and the purified thyroglobulin. (From Doniach and Roitt, *J. Clin. Endocr. & Met.*, 17:1293, 1957.)

patients with Basedow's disease, but not in normal controls. He suggested that Basedow's disease was not only a state of hyperthyroidism but also of dysthyroidism.

In 1915, Beebe[2] treated Graves disease with thyroid antiserums, achieving a modicum of success.

In 1927, Hektoen, Fox, and Schulhof[3] observed the development of precipitating antibodies in the serum of rabbits receiving injections of saline extracts of thyroid, presumably thyroglobulin, from another species. These precipitins were organ-specific, reacting only to thyroid extracts, but not species-specific. They reacted to thyroid extract from a species different from the one used to stimulate the formation of antibodies.

In 1942, Lerman[4] injected human thyroglobulin into rabbits and detected circulating precipitins to rabbit thyroglobulin. Myxedema occurred in the immunized rabbits in a few instances.

Witebsky and Rose[5,6] and associates originally produced antibodies by sensitizing one rabbit to the thyroglobulin of another rabbit. They found it necessary to use Freund's adjuvant, a mixture of mineral oil and killed mycobacteria, to enhance and prolong the formation of antibodies. They demonstrated circulating antibodies by three procedures; precipitation (PPN), complement-fixation (CF), and tanned cell agglutination (TCA). In the TCA method, red cells are exposed to a weak solution of tannic acid to facilitate the adsorption of the antigenic protein. The coated red cells are then agglutinated in the presence of antibodies to the coating protein. The PPN test, in which undiluted rabbit serum was mixed with serial dilutions of thyroid extract, was very insensitive compared to the other two tests. Antibodies were demonstrated in 38 per cent of fifty rabbits by the CF method, and in 91 per cent of thirty-two rabbits by the TCA method. These

antibodies were specific for extracts of thyroid gland and did not react with extracts of other rabbit organs such as liver, spleen, kidney, heart, lung, pancreas, or adrenal. However, the anti-

Fig. 2. Estimation of specific thyroid antigen content of rabbit thyroid glands by complement-fixation test, using rabbit antiserum containing high titer of organ-specific rabbit thyroid antibodies.

With normal rabbit thyroid a strong reaction is demonstrated with a high dilution of the thyroid extract. The other four rabbits had been previously immunized with thyroid gland extracts. Rabbit 223 had a high titer, 220 and 215 medium titers, and 224 but a trace of circulating antibodies. (From Rose and Witebsky, *J. Immunol.*, 76:417, 1956.)

thyroids. Also rabbits produced antibodies to injected extracts of their own thyroid glands.

Witebsky and colleagues[6,7] then prepared a nearly-pure rabbit thyroglobulin which was injected into the footpads of six rabbits in standard fashion. All six developed antibodies against rabbit thyroid extract as shown in Figure 1, suggesting that thyroglobulin was the constituent of thyroid extract responsible for the immunization measured by TCA.

The logical next step was to demonstrate, if possible, *in vivo* damage to rabbit thyroid glands in association with antibody formation. They[3] first showed that the measurable thyroid antigen content of thyroid glands of rabbits which had been immunized and had produced circulating antibodies was diminished, and that the decrease was related to the intensity of the antibody response of the rabbit (Fig. 2). This was verified in another group of nine rabbits in whom one-half of the removed thyroid gland was saved for

histologic examinations. These[8] revealed alterations in the histology (Fig. 3) which prompted Douglas Riggs, a colleague with special interest in thyroid diseases, to say, "That looks like Hashimoto's thyroiditis."[9] The intensity of the histologic change, like the decrease in antigen content of the opposite lobe, was correlated with the titer of circulating antibodies (Fig. 4). These studies were confirmed with purified thyroglobulin, the histologic changes being similar. Similar results were also observed when the antigenic extract was injected into the same animal from whom the portion of thyroid gland used to prepare the extract originally came. These various findings were impressive evidence, indeed, for the presence of true auto-antibodies.

While this work was being pursued, an entirely different approach to the problem was started by Roitt and co-workers in England. These investigators had the happy thought that the increased gamma globulins in Hashimoto's thyroiditis probably reflected circulating antibodies to thyroglobulin. They extracted thyrotoxic or normal thyroid glands with saline, and prepared a purified thyroglobulin antigen from this. In their earliest report[10] this antigen was layered over the serum of nine patients with Hashimoto's thyroiditis yielding detectable precipitins in seven. They later[11-13] mixed the antigen and the serum with agar so that diffusion, mixing, and precipitation occurred very slowly in a gel medium (Fig. 5A). By this technique, precipitins were demonstrated originally in twenty-five of thirty patients with Hashimoto's disease. Similar precipitin reactions were found when purified thyroglobulin was used. That thyroglobulin was the antigen in the crude thyroid extracts was shown by confluence of the precipitation lines of purified thyroglobulin and thyroid extract on an Ouchterlony plate (Fig. 5B).

The antigens in the thyroglobulin and thyroid extract preparations were also found to have identical mobilities on immuno-electrophoresis in agar. As many as three distinct antigens could be identified in purified thyroglobulin by means of the precipitin reactions. Fractional electrophoresis of the Hashimoto serum showed that the precipitins were only in the gamma globulin fraction. The serums gave negative reactions to saline extracts of human liver, kidney, spleen, lymph node, parotid gland, and brain. A narrow species specificity was also demonstrated, serums reacting only with extracts from thyroid of the chimpanzee and monkey, in contradistinction to the early observations of Hektoen and his associates using rabbit antihuman thyroid serum.[3] High levels of circulating antibody were found—values as high as 5.2 mg. antibody protein per ml. serum being recorded. The molar ratios of antibody to antigen in the specific precipitates were low (4:1 to 2:1) indicating a small number of combining sites on the antigen.[13]

By the time their clinical paper was published, Doniach and Roitt had studied 144 cases of Hashimoto's disease finding precipitins in 109 or 76 per cent. The antibody titers tended to be highest in untreated patients, lower in those treated with desiccated thyroid, and often disappeared after thyroidectomy. They also demonstrated precipitins in six of thirty-three patients with myxedema, four of six with subacute thyroiditis, and in

none of 209 other patients with thyrotoxicosis, nodular goiter, or Reidels thyroiditis.[11]

With the publication of the first preliminary report by Roitt et al in 1956, Witebsky and co-workers[14] applied their sensitive TCA technique to a series of patients, finding antibodies to thyroglobulin in 43 per cent of forty cases of thyroiditis and in 10 per cent of twenty-nine cases with other thyroid diseases. They differed in finding no antibodies in fourteen patients with Hashimoto's thyroiditis; however, it is quite apparent from succeeding reports that this is a matter of pathologic definition of disease rather than of immunologic discrepancy. Goudie and co-workers[15] and Trotter and colleagues[16] promptly verified the observations of Roitt and Doniach in Hashimoto's disease. White[17] demonstrated that fluorescein-labeled antibody from a patient with Hashimoto's thyroiditis accumulated in the colloid of the remaining acini when the serum was brought in contact with slices of the patient's own thyroid. He also showed[9] that complement-fixing (CF) antibodies could be demonstrated in nearly every case of Hashimoto's disease when he used antigen prepared from thyrotoxic gland. Trotter and colleagues[16] made the same observation, but noticed in addition that antigen from normal glands was ineffective. They suspected that the antigen of the complement-fixation reaction was different from that of the precipitin reaction, a suspicion that was borne out later as we shall see.

(From Belyavin and Trotter, *Lancet*, 1:648, 1959.)

V. Antibody-sensitive component of reaction IV.
VI. Antigen-sensitive component of reaction IV.

The early observations so far outlined, led directly to much further work of an expanded nature, and within the past year, it has become quite evident that more than one thyroid antigen is involved, and that auto-antibodies can be detected in many types of thyroid diseases besides thyroiditis.

Roitt and Doniach,[18] following the lead of Trotter and co-workers, found that the CF antibody

was distinct from the precipitin, in that absorption of precipitins from Hashimoto's serum with thyroglobulin had no effect on the titer of CF antibody. As with precipitins, only the gamma

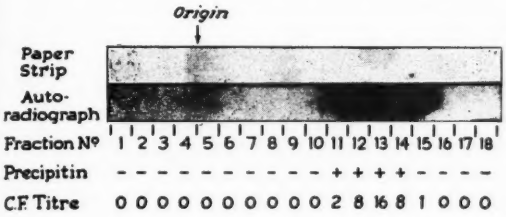

Fig. 7. Immunoelectrophoresis and autoradiography of the electrophoretic strip of a radioactive thyroid extract, showing correspondence between site of precipitating antigen, complement-fixing antigen, and radioactive thyroglobulin. (From Anderson, Goudie and Gray, *Lancet*, 1:644, 1959.)

globulin fraction of serum gave a positive complement-fixation reaction. Cell fractionation studies of homogenates of fresh thyrotoxic gland revealed the CF antigen to be localized to the microsome fraction. It is thus an intracellular antigen in contrast to thyroglobulin which is an intrafollicular antigen. The richest source of CF antigen was thyroid from hyperthyroid patients; however, they thought they detected it in normal thyroids. This CF antigen was organ-specific and cross-reacted only with thyroid from closely related species (chimpanzee and monkey).

These observations have been verified by Belyavin and Trotter[19] who also found that the CF antigen from thyrotoxic glands was localized to the microsome fraction of thyroid cells. They distinguished this CF reaction to a "microsome factor" antigen (which they called antibody-sensitive based upon the CF pattern—shown in Figure 6) from a second CF reaction to thyroglobulin (which they called antigen-sensitive and which occurred in a few Hashimoto serums). They also established that the thyroglobulin concentration of thyroid gland extracts was independent of the total complement-fixing potency. The CF reaction to thyroglobulin has been studied in some detail by Anderson, Goudie, and Gray.[20] On the basis of immuno-electrophoretic correlations (Fig. 7), and demonstration of the reaction with chemically-purified thyroglobulin, they concluded the CF antigen in non-toxic thyroid extracts must be thyroglobulin. The CF antibodies to thyroglobulin were only present in low titers and could be blocked by precipitins. They do not contribute significantly to the CF antibodies formed in response to extracts of thyrotoxic thyroid glands.

Anderson, Goudie, and Gray[21] also studied the CF reaction to extracts of thyrotoxic glands in some detail. They found the antigen equally abundant in glands from thyrotoxic patients and goitrous cretins, favoring the idea that its abundance is related to epithelial hyperplasia. They presented evidence that a single antigen-antibody system was involved and that the reaction was

auto-immune in nature. A characteristic reaction pattern was observed in which the titer of the serum was nearly constant with all reacting dilutions of extract, and conversely. Also the titer of thyroid extract was constant when tested with different positive serums. Autologous tests in which both the serum and thyroid extract came from the same individual were performed on seven thyrotoxic patients, being positive in all.

It thus seems reasonably clear at this point that two different antigens can stimulate antibodies to thyroid tissue. One is thyroglobulin to which precipitating, tanned cell agglutinating, and complement-fixing antibodies have been demonstrated. The other is an unknown substance in the microsomes of thyroid cells to which only complement-fixing antibodies have been demonstrated.

These observations have been a stimulus to reconsiderations of the incidence of thyroid auto-antibodies in the major thyroid diseases. Roitt and Doniach[18] measured thyroid auto-antibodies in large groups of patients by three techniques simultaneously—PPN, TCA, and CF with extracts of thyrotoxic glands. With the more sensitive and all-inclusive methods they found a high incidence of antibodies in various thyroid diseases (Table

I), most prominently in Hashimoto's thyroiditis and myxedema where the highest titers were found. In general, low titers were found in the other thyroid diseases and were associated with

*Including 142 women over 50 years of age of whom 16% had positive tests.

having more low titers than high. Hashimoto's cases of recent onset had roughly the same total incidence but many more with high titers of antibody. These results, added to those of the others, support the idea that spontaneous myxedema, like chronic thyroiditis, may be the end result of thyroid auto-immunization. These immunologic observations also support the inferences from histologic studies, that Hashimoto's thyroiditis and spontaneous myxedema arise from the same or similar pathologic processes.

The incidence of circulating antibodies in patients with various thyroid diseases (Table IV) is in striking contrast to that observed in patients without thyroid disease, where no matter what method or what author, the incidence figures are low (Table V).

Several other correlations have been established between pathologic anatomy and circulating antibody levels. Stuart and Allan[25] observed a direct relationship between basement-membrane irregularities in the thyroid follicles and the occurrence of high antibody titers in thirty-one patients with thyrotoxicosis, Hashimoto's disease, or subacute thyroiditis. The basement-membrane changes were widespread and severe in the cases with thyroiditis and of lesser degree in those with thyrotoxicosis. They were usually associated with lymphocytic and plasma cell infiltrations.

TABLE VI. ASSOCIATION BETWEEN RESULTS OF SKIN TESTS WITH THYROID EXTRACT AND CIRCULATING PRECIPITATING ANTIBODIES

(Data of Buchanan et al[30])

PPN Test*	Skin Test		
	Negative	Weak	Strong
Positive (15)	27%	7%	66%
Negative (37)	87%	13%	0%

*No. of cases in parentheses.

Goudie, Anderson, and Gray[26] recorded autopsy findings in seventy-seven patients without known thyroid disease who had complement-fixation tests. Nine had positive tests. Eight of these were women who had a common abnormality of the thyroid gland—lymphocytic infiltration associated with large eosinophilic flattened thyroid epithelial cells which form small acini containing little or no colloid. The ninth was a man whose complement-fixation reaction was not specific and whose gland was normal. Four of the eight women had hepatic cirrhosis. Of 486 patients with a wide variety of diseases only those with a diagnosis of liver necrosis and cirrhosis had a significant incidence of positive thyroid complement-fixation tests. Of 300 postmortem thyroids examined, eleven were from women with hepatic necrosis or cirrhosis, and seven of them showed the thyroid changes described above. A very suggestive association is evident between the thyroid abnormality and liver cirrhosis in women. Luxton[27] had observed the occurrence of post-necrotic cirrhosis in a woman with Hashimoto's thyroiditis. The hepatic fibrosis in association with plasma cell and lymphocytic infiltration tempted him to speak of "Hashimotosis of the liver." I suspect a significantly increased incidence of positive complement-fixation tests and microscopic thyroid abnormalities would be found, if looked for, in the kind of patients with liver abnormalities described by Bearn, Kunkel, and Slater[28] and by Bartholomew, Hagedorn, Cain, and Baggenstoss.[29] Many of us are suspicious of an auto-immune mechanism in the etiology of post-necrotic cirrhosis. Perhaps auto-antibodies form a common denominator between this liver abnormality and Hashimoto's thyroiditis.

It is quite apparent from this brief résumé that the original view that thyroid auto-antibodies are of importance mainly in Hashimoto's thyroiditis has had to be modified quickly. So has the original view of pathogenesis which supposed that leakage of thyroglobulin due to thyroid damage led to antibody formation, which in turn attacked and further damaged the gland, starting a chain reaction. On the other hand, the suggestion that spontaneous myxedema may be the end result of auto-immunity and thyroiditis has been strengthened.

The possibility exists that the presence of circulating antibodies in thyroid disease is an incidental by-product of the damage to the gland. However, this would not explain the experimental production of comparable lesions in rabbits immunized against their own thyroids. A more likely possibility, suggested by Roitt and Doniach, is that the antibodies act indirectly by a delayed hypersensitivity reaction. The fact that Freund's adjuvant containing killed tubercle bacilli had to be used by Witebsky and Rose to get any significant thyroid damage in rabbits, favors this hypothesis. The positive skin tests observed by Buchanan, Anderson, Goudie, and Gray[30] with thyroid extracts also favor this. They showed that intradermal injection of a saline extract of thyroid gave a tuberculin-like skin reaction in patients with thyroid disease, particularly those with Hashimoto's thyroiditis or primary myxedema. Strongly positive reactions were seen only in those with circulating precipitins (Table VI). With one exception, positive skin reactions did not occur in controls without thyroid disease. Biopsy of an area of strong reaction revealed edema and hemorrhage into the skin with polymorphonuclear infiltrations. Some such sensitization may be the essential factor in thyroid damage. Other antibodies besides those so far identified may cause the actual damage to the thyroid, those we measure being indicators but not the cytotoxic agents.

This is as far as the path goes along the autoantibody trail. Reports will be appearing "thick and fast," and what is concluded today will undoubtedly be modified tomorrow. Whatever the outcome, this is clearly a fascinating and fruitful development in the field of thyroid diseases.

Acknowledgments

I am grateful to the authors of the articles cited and to the editors and publishers of the journals in which the papers appeared, for their kind permission to reproduce their work in this review.

Addendum

Since submission of this paper, Pulvertaft, Doniach, Roitt, and Vaughan Hudson (Lancet 2:214, 1959) have reported on the cytotoxic effects of Hashimoto serum on human thyroid cells in tissue culture. Surgically excised thyroid glands were prepared by trypsin dispersal of the thyroid cells, and direct examinations for cytotoxic changes were made by phase contrast microscopy after incubation with normal and Hashimoto serum. Thyroid cells in contact with normal serum survive unchanged up to eighteen days. With Hashimoto serum, few surviving thyroid cells are seen at eighteen hours, even though lymphocytes, monocytes, and neutrophils from the same gland retain their normal appearance and motility. Replacement of normal with Hashimoto serum after incubation for eighteen hours resulted in cytotoxic changes rapidly. Hashimoto serum destroyed thyroid cells cultured from the patient's own gland as well as from thyrotoxic and non-toxic nodular glands. Thyroid cells grown in normal serum for more than thirty-six hours seemed to acquire a protective coating and could no longer be affected by Hashimoto serum. Heating Hashimoto serum at 56° C abolished its cytotoxic effect, indicating that the cause of the cytotoxic action was not the antibodies to the microsomal factor or thyroglobulin, since these antibodies are heat stable.

CIRCUMSCRIBED PULMONARY LESIONS

The following outline is offered to physicians encountering lesions of the lung, mainly as a plea against complacency in diagnosing conditions which appear to be benign but may definitely be found to be malignant upon closer observation.

Coin Lesions of the Lung

(a) Single
(b) Circumscribed
(c) Noncavitary
(d) Without distal obstructive changes

Types of Coin Lesions

Malignant—one-third
- Primary bronchogenic carcinoma
- Alveolar cell carcinoma
- Metastatic carcinoma or sarcoma
- Bronchial adenoma
- Primary connective tissue tumors
- Mesothelioma

Benign—two-thirds
- Granulomas
  - Tuberculosis
  - Fungi
- Hamartomas
- A-V fistula
- Abscess
- Hematomas

Specific Information for Diagnostic Workup in Coin Lesions

(a) Old films
(b) Skin tests
(c) Tomograms (to reveal calcium)
(d) Cytology (if raising sputum)
(e) Bronchoscopy (only if centrally located)
(f) History of hemoptysis
(g) Sedimentation rate
(h) Search for primary tumor

Calcification in Coin Lesions

If calcium is
(a) Solid or diffuse
(b) Laminated
(c) Central core
then benign.

If calcium is
(a) In flecks
then may be malignant.

Calcified Coin Lesions (Benign)

Removed surgically if:
(a) They enlarge
(b) Develop radiolucency
(c) Become symptomatic (because of spread of infection, not cancer).

After All Tests Are Completed, two-thirds or more of lesions remain a mystery (depending on cytology laboratory).
Final test—Exploratory Thoracotomy

At Thoracotomy—

Biopsy
- Enucleation (hamartoma)
- Wedge resection
- Segmental resection
- Lobectomy

One-half of specimen for pathology and
One-half for bacteriology
Definitive surgery
- Further resection or not, depending on fresh frozen tissue diagnosis.

Malignant Coin Lesions

Survival good if asymptomatic and removed early.
Absence of blood vessel invasion most important in prognosis.
Peripheral location enhances resectability.

Coin Lesion in Twenty-Year-Old Most Difficult Decision

If calcified—no surgery
Not calcified—possible surgery
- Could be adenoma, A-V fistula, abscess, or metastatic carcinoma or sarcoma.

Each case is individualized.

Summary—Coin Lesions

(a) One-third are malignant
(b) Few are diagnosable without exploratory thoracotomy.
(c) Complacency will lead to trouble.
(d) Conservative resection for fresh frozen tissue diagnosis.
(e) Risk roughly is that of laparotomy

ROBERT W. JAMPLIS, M.D., ET AL
Palo Alto Clinic

reading, Reading, READING

Dr. Randall Jarrell, in a *Saturday Evening Post* article, "The Appalling Taste of Our Age," states that words are the chief American industry. The opinion is substantiated by Dr. I. Donald Fagin's statistics published in the September 1959 issue of the *Mississippi Valley Medical Journal:* "... in 1957, more than 200,000 medical articles appeared in over 4,000 medical journals; 659 journals of medical interest were published in the United States alone."

The main points of Dr. Fagin's succinct article are the pertinent discussion of five motives for publication and six solutions to the problem of "Too Many Words" in medical literature. The solutions are given, Dr. Fagin concludes, "without much hope that they will meet with approval except by the medical *reading* public." If the seemingly inexhaustible writings are to continue to pour in, the reader must do something about his part in the communication process: "receiving" the meat of the writing that the "sender" is issuing.

The components of an effective reading pattern are these:

1. *Confidence.*—A person can read just as fast as he thinks he can. We have mental blocks on our reading proficiency, which discourage our even starting to read a given piece of literature. Here, *confidence* implies that faith which comes from a knowledge of the task to be accomplished.

2. *A Brief Fixation Time.*

3. *A Wide Reading Span.*—In connection with these two aspects of the reading process, a representative of the American Optical Company states that the average reader *can* read twenty to twenty-five printed characters at 1/100th of a second; the average reader does read ten to twelve characters at 1/25th of a second.

4. *Absence of Vocalization.*—Ineffective readers vocalize in two areas: (a) with the lips and (b) in the larynx. A third spot in which words are "said" is in the brain. Despite the controversy on the point as to whether this is a form of vocalization, the more efficient reader is not conscious of word formation as he reads; the imprint on his consciousness is an idea, the objective of most contextual reading.

5. *Avoidance of Regressions.*—At the Reading Center in New York City, the statement is made that because of regressions (going back to pick up a point), the average reader spends ten times as much time as he need spend on a given piece of reading. If this figure strikes you as incredible or exhorbitant, check yourself the next time you are aware of regressing in reading. You will, in all probability, come to accept the figure as not unreasonable.

6. *A Rhythmic Reading Pattern.*—To establish a rhythmic pattern to suit the purpose and type of the reading being done helps to break word-reading. The two-, three-, or four- fixation-per-line pattern is recommended for the beginning reader and for certain types of literature. The proficient reader may read diagonally from the upper left-hand to the lower right-hand margin, or he may fix only in the center of the lines and read directly down the center of the page. Such known patterns among some readers are usable, *depending upon the purpose of the particular reading.*

7. *A Flexible Pace.*—The "poor" reader reads everything he approaches at the same rate. In newspaper reading, the international news, the sports, the editorial page, the comics—all of these features are read without consideration of their importance to the individual reader, and usually at a plodding, pedestrian rate. However, there are those who need to "reduce speed" for fulfilment of their reading purposes.

8. *Concentration.*—This highly intangible quality of reading is contingent upon development of the other components. The old wives' tale that "The slow reader gets more out of his reading" has been disproved. Testing has shown that it is the slow reader who regresses because of lack of

concentration, the end result of the reading being minimum retention of the material read.

You can make three approaches to your reading improvement.

1. *On your own, with your every-day professional and leisure reading.*

As in any self-development, or do-it-yourself campaign, this is the most difficult of the three approaches to pursue. Confidence runs low; self-motivation peters out; empirical, inaccurate testing of possible progress is less than satisfying. However, a few suggestions:

(a) Devote a given time—ten to fifteen minutes a day will pay dividends—to losing some of the old, costly reading patterns.

(b) Draw two or three light vertical equidistant lines (depending upon width of the column) down the columns of three or four columns of the newspaper or journal you wish to read. These lines serve as your fixation points, to discourage word-reading and sweeping back to the left margin, and to encourage a rhythmic pattern.

(c) Since the purpose in reading many of the popular comics is enjoyment of the punch line in the last frame, develop better reading habits by reading the balloons (the characters' dialogue) by the line, rather than by the word. With concentration, you can read many of the shorter "speeches" in one fixation. The very nature of the majority of the comics and the style of print make this homely exercise an effective aid in reading improvement.

(d) Discipline yourself brutally to break the habit of regressing. "Going back" is a luxury almost all readers cannot afford.

(e) Force yourself to read faster by scanning short newspaper articles and magazine news items. The brevity of these features lends itself to a quick self-test on how much information and detail you are able to assimilate. Caution: keep in mind that some of the details in the articles are likely unimportant and unnecessary to your purpose in reading the particular piece; so, don't assume that fallacious notion that you should remember *everything* included in the writing.

(f) Develop a flexible pace. Determine your purpose for reading a given piece and establish a pattern to achieve that purpose.

2. *The workbook or machine approach to assist in the self-help campaign.*

There are literally scores of workbooks on the market. In price they run from seventy-five cents to around six dollars. In choosing a book, you would do well to select one that gives a great deal of space to exercises and drills involving reading. Many of these publications spend too many pages on general discussion of reading and too little in involving the reader in actual improvement. In reading, as in any other endeavor, learning results from doing, not from reading about how to do.

Electric and pneumatic reading machines are geared for variable rates, the speed to be determined by the reader. These machines have a shutter, a rectangle of reflected light, or a rod moving down the page to pace the reader.

The five or six best known of these machines range in price from thirty-five dollars to approximately one hundred dollars.

In addition to helping break inefficient reading habits, the value of pacers to the individual is twofold. They serve as a motivator; too, they give the reader rather accurate evidence of his progress.

Some use is made by individuals of the various tachistoscopic (flash meter) devices on the market. These aid in widening the reading span and reducing fixation time.

3. *Formal class training in developmental reading.*

The advantages of having formal training under the direction of a qualified teacher are apparent, especially in a skill subject such as reading. Because developmental reading encompasses considerably more than mere increase in rate, the teacher is indispensable to the individual in this training if the objectives of the course include more than just improvement of the physical aspects of the reading process.

If you contemplate enrolling in a reading course or instituting such a course in your training program, consider two or three factors well. (a) The course should be at least 10 weeks long. (b) Classes should meet more often than once a week. (c) At least thirty hours should be devoted to the training.

Purdue University's extensive ten-year experience in developmental reading has acquainted the personnel with all phases of materials, equipment, and curriculums. (Incidentally, about 1000 students take the course each semester. The average gain in rate of speed is approximately 100 per cent with some gain in comprehension). Too,

Purdue has personnel to establish or conduct developmental reading courses for educational and industrial organizations.

If you decide to improve your reading habits (the first step is the firm decision), you can. Any *conscientious, sustained* effort in reading improvement will pay dividends. Dividends in less strain in workaday reading and more pleasure in leisure reading.

E. GLENN GRIFFIN

EMPLOYMENT PROBLEMS OF OLDER WORKERS

At the turn of the century, only four out of ten persons in the United States could expect to see their sixty-fifth birthday. Now, thanks to the results of scientific research, two out of three reach that age. This extension of life expectancy has pushed the average age from forty-five in 1900 to seventy today. An examination of the same period reveals that the total population doubled, while the number in the forty-five to sixty-four age group tripled, and the number in the sixty-five and over group quadrupled. And we are still adding years of life. Eminent medical authorities report that the human body is engineered to live up to 125 years, if in good health, and they believe that the average life span of individuals born in 1975 may well be close to ninety years.

All this means one thing—that people in the United States are living longer and consequently can look forward to more years of activity and productivity. It is at this point—the growing gap between the life span of the average American and the span of his work life—that one of today's most serious social problems appears.

The problem is based primarily on the fact that personnel policies and hiring practices relating to workers aged forty or over have not kept pace with advances made in medical science or in industry, or with conditions under which people live and work today. The erection of arbitrary age barriers to employment flag down some people at age thirty-five, and even earlier in some occupations. The critical age area, however, based on studies by the U. S. Department of Labor, appears to be age forty-five. Further research by the Minnesota Department of Employment Security points out that 75 per cent of the job openings received by the Twin Cities State Employment Service offices carry age restrictions, with 54 per cent barring from consideration workers over forty-five.

A closer look at population figures of this age group reveals some dramatic statistics regarding the scope of the problem. In 1900, citizens forty-five and over numbered 13.5 million. By 1955, this figure had exploded to 47.5 million; now the U. S. Bureau of the Census estimates this age group will soar to 56.5 million by 1965.

One-third of the persons coming into the Minnesota State Employment Service offices seeking employment are over age forty-five; yet we are able to find jobs for only one-fifth of them.

When older persons are excluded from gainful employment, the proportion of producers to consumers is reduced. This reduction causes lower standards of living, restriction of earning power, loss of individual dignity and self respect, and family and social pressures—all adding up to higher taxes to cover increasing costs of assistance, relief, and welfare programs.

Far too many employers cling to the notion that theirs is a young man's business. Their attitude appears to be that time is the true measure of an individual's age. This belief overlooks the fact that some people are young at seventy and others are old at forty, and it seems to support the idea that a man can be a valuable and productive worker one day, reach a magic age, and be a dud the next day. Chronological age is not a reliable measure of a man's productive capacity and, sooner or later as more and more workers join the ranks of the forty-plus, the traditional attitudes which are responsible for age restrictions will have to give way to the simple truth that ability is the logical guide to hiring.

But while the plight of the older worker is attributable primarily to the erection of arbitrary age restrictions, other factors contribute to the problem. Decreasing opportunities in agriculture and self-employment, for example, have forced many older persons into inactivity in rural areas or into migration to urban areas where their lack of marketable skills intensifies their employment problems. This situation is serious and requires careful evaluation of work potentials and possible vocational training.

Many older job seekers often create their own problems. Because they have worked for a long period of time, many do not know how to look for a job. Many fear the changes and adjustments they will have to make. Many worry about being rejected; and when their job-hunting efforts are unsuccessful, they adopt a defeatist attitude which

only complicates their problem. Many lack a realization of their own limitations and continue to make unrealistic demands for wages, locations, or working conditions. On the other hand, many sense that they are slowing down and either talk about it too much to the employer or cover it up to their own disadvantage. Because many are insecure, they resist changes in occupation and pay and find it difficult to adjust to new people and situations.

The negative factors just outlined are surpassed by the favorable attributes of older workers. Their reliability, serious attitude, and definite desire to work are important. Probably more important is the fact that they can bring to the employer maturity; maturity based on years of experience and the development of skills, knowledge and abilities. With the combination of all these positive factors, they can offer the employer a tremendous potential.

Armed with the knowledge of the older worker and his problems, many unions, religious groups, and other organizations are counseling older workers in an effort to prepare them for the time when they may have to consider a re-evaluation of their skills for entry into other types of work.

The Minnesota Department of Employment Security is applying its research findings to actual operations. Its offices in Minneapolis, St. Paul, and Hopkins have set up special services for older job seekers, and plans are under way for extending the program to the other thirty offices throughout the state. Special services for older workers require specialized employment counseling, testing, intensive job development and other placement activities. The plan is to assist in every possible way, qualified older workers and to promote for them equal opportunities for employment in competition with other workers with similar qualifications.

The program is based on a three-way educational approach. First, Employment Service staff members are receiving training designed to equip them to work effectively with older applicants. Second, older workers themselves are being briefed regarding the best methods for conducting job search campaigns. Third, intensive educational efforts are directed at employers urging them to hire on the basis of qualifications regardless of age.

This program, established late in 1956, is moving from its formative stages and is beginning to show results. Placements of older workers have shown a definite increase. This gain is significant in that it occurred during a period of difficult labor market conditions.

It is clear, however, that more is needed than even the best service the Employment Service can offer. Our efforts must be supplemented by an aroused community consciousness as to the need for positive action in meeting the employment problems of Minnesota's forty-plus citizens.

MERLE S. KINVIG
Minnesota Department of Employment Security

AVAILABLE OPPORTUNITIES FOR BETTER HEALTH

Good health is man's most important asset, and one would naturally think that everybody would take advantage of all that medical science has to offer for the preservation and maintenance of health. Unfortunately, this is not true, for a much too large percentage of people are still not availing themselves of all these better health opportunities.

Fortunately, just during the past few decades, medical science has shown remarkable progress. Advances in medical research have resulted in the development of many new discoveries, new technical accomplishments, new drugs, and better facilities for the diagnosis, prevention, and cure of disease.

Large sums are being contributed to and spent annually by organizations engaged in medical research, public health education, and preventive medicine. Large expenditures are being made for the construction of new hospitals, clinics, and diagnostic centers, where better facilities are provided for the diagnosis and treatment of disease. Such organizations as the U. S. Public Health Service, the American Cancer Society, the polio foundation, the various heart associations, the tuberculosis associations, and many others are engaged in public health education and research for the prevention and cure of disease.

Throughout the country, industry is also contributing toward the health of employes. Industry has developed safety programs and safety devices for the education and protection of the worker. Most industries have established medical departments with medical personnel engaged in industrial medicine and surgery for the benefit of their employes. Periodic and interval physical examinations of employes are made in an attempt by industry to

properly evaluate the health of the employe and preserve his employability. Industry is continuously making an effort to retain employes on the job by proper placement at work within the capabilities of their physical condition. Industry has found that it is much more difficult to replace experienced and well trained employes than it is to replace machines.

Some would wonder, then, why more people do not take advantage of all of the above mentioned health opportunities. This appears to be due to several reasons. Fear, lack of knowledge or misinformation regarding medical matters, prejudice, complacency, procrastination, neglect, and the financial status of the individual tend to control people's thinking relative to health matters.

As far as preventative medicine is concerned, there are many concepts to be considered. Primarily, there is the acceptance by the patient. A survey shows that only about five per cent of patients seek out their family physician to seek medical care or advice in preventing disease. People in apparent good health do not seek out their family physician strictly for the purpose of maintaining their "well" state of being.

Many physicians have tried to encourage well patients to have their eyes examined, to have a urine examination, to have tests or x-rays for tuberculosis, to have examinations for heart disease, tests for diabetes, and periodic physical examinations for the detection of disease in the early stages. Who takes advantage of such preventive techniques? Too often, not the patient who is having difficulty in seeing from glaucoma or the worker who does not like to wear protective goggles. Too often, not the man who is coughing, nor the man whose family is known to have diabetes, nor the patient who is overweight or is having symptoms of heart disease or high blood pressure. These people, like so many others, seem to be more afraid of learning something is wrong than they are of preventing serious consequences. Fear of finding out is actually greater than the fear of actually having the disease.

As far as lack of knowledge and proper information to guide people's thinking and prejudice concerning medical and health matters is concerned, efforts are constantly being made by the various public health services, foundations, research medical centers, and by the medical profession to properly inform the public authentically regarding health problems. However, these efforts are being nullified to a considerable extent by the tremendous amount of misinformation given the public through commercial advertising of medical products, treatments, cures, and so forth, via the radio, television, newspapers, and other publications. A survey will show that by this exploitation the American public spends annually for these useless drugs, nostrums, cold remedies, vitamins, and others, enough money for all their medical bills for good medical care.

As for complacency, procrastination, and neglect by the individual relative to health matters, only continued efforts in public health education are needed. There are still large numbers of children and young adults who have not yet had polio shots and other immunizations. Relative to the cost of medical care and the economic status of the individual as a deterrent factor in the acceptance of the opportunities available for proper and adequate medical care, this factor is in reality not true. It depends to a great extent on the importance which the individual puts on what he should spend for the preservation and maintenance of good health. It depends on where he puts the cost on his monthly budget list. Statistics will show that the American public spends more for cigarettes alone than it does for medical care, much more for liquor, and many times more for luxuries and recreation. Today, with the availability of prepayment insurance plans for medical and hospital care, proper budgeting should make it possible for the majority to take advantage of the opportunities for better health.

It would appear, then, that further effort should be made in educating the public of the availability of their health opportunities. The great benefits of preventative medicine should be stressed, and more people pursuaded to accept them.

Evidence exists that a periodic measurement of the health of supposedly well individuals often leads to the discovery of significant, previously unrecognized disease, that such is frequently still asymptomatic, and that, as would be expected, better results are frequently enjoyed when these diseases receive attention in the early stages.

Although health maintenance is primarily the responsibility of the individual, an industrial health program represents management's recognition of its obligation to provide a safe work environment and its opportunity to promote better health among its employes.

Management, by instituting a program of periodical examinations of employes, is attempting

to do its part in preventative medicine and health education. The value of these examinations will depend, of course, upon the scope and extent of the examinations. It will depend, however, primarily upon two things. First, the medical history which the examiner is able to obtain, and secondly, the physical examination. It is therefore important that the employe provide the medical examiner with complete details regarding his past medical history. This, along with the physical examination, many times may prove to be very beneficial to the employe. Conditions needing treatment will be brought to his attention, sometimes in the early stages, where the most good can be done. While some employes may be examined regularly by their own private physician, there may be many other cases in which the physical examination conducted in the industrial medical department may be the only one that he has had for a considerable period of time.

In this manner, management in industry is then playing a significant role in modern medicine in attempting to get more people to take advantage of all the opportunities available for better health.

O. L. McHaffie, M.D.

MEDICAL LEGAL SECTION

Attention is called to a new section on Medical Legal Opinion which appears for the first time in this number of Minnesota Medicine (page 1825). Information of interest in this field will be published each month in the future.

The subject this month is a Syllabus by the Court concerning action taken with regard to a contract with a laymen allowing him to practice the science of healing in violation of Minnesota law.

The January number will present selected quotations from Minnesota laws concerning the practice of medicine, hospitalization, Blue Cross and Blue Shield.

The February number will contain selections from Supreme Court rulings concerning the practice of medicine.

The March number will give quotations from rulings of the American Medical Association and other organized medical groups.

A QUOTATION FROM AN OPINION ON THE MEDICAL PRACTICE ACT

In an opinion handed down by Justice Jaggard of the Supreme Court of Minnesota on December 22, 1905, in the case of the State versus Oredson, the following concise statement defining the object of the Medical Practice Act was made:

"On the contrary, its plain object was to prevent the public wrong of practicing medicine without a license. The act was not enacted for the benefit of any profession or of any school or theory of medicine. It was designed to secure the public in whole and in every part from quacks, humbugs, and charlatans masquerading under the venerable and honorable titles of surgeons, physicians, and doctors, and to protect the public in a just reliance upon the one using these titles as a man of proper education and sufficiently trained in the sciences involved. A just enforcement of that act would tend to prevent the most deplorable swindling of the ignorant poor, who can least afford to pay for the luxury of deception, and who are the most likely to be the dupes of ostensible practitioners, whose competency has not been determined by law, and whose moral deficiencies are evidenced by their false pretenses. Its terms should be construed, so far as reasonably may be, so as to tend to eliminate the suffering of an individual from the misuse of inert drugs when potent ones are needed, and of powerful agencies productive of ill where proper ones might bring relief or effect a cure, so as to avoid many evils of malpractice, and so as to minimize the exposure of the community at large to the spread of avoidable pestilence. The act is at once a statute of frauds and a health ordinance."—(State v. Oredson, Supreme Court of Minnesota, December 22, 1905, 96 Minn. 509, 105 N. W. 188.)

CORRECTION

In the editorial entitled "Digitalis Treatment of Heart Disease," published in the November, 1959, number of Minnesota Medicine, page 1637, the word "rapid" was inadvertently omitted from the seventh sentence in the first paragraph. The sentence should read: "For those patients who do not require *rapid* digitalization, the whole leaf product is still the best."

President's Letter

THROUGH THE LOOKING GLASS

"The time has come," the walrus said, "to speak of many things; of ships and shoes and sealing wax, of cabbages and kings."

"Cabbages and Kings" was the title of an interesting column many years ago in the *St. Paul Pioneer Press,* edited by the late Larry "Ho" Hodgson. This column was replaced by Paul Light and more recently by "Once Over Lightly," edited by the humorous Roy Dunlap.

Now the time has come for me to write my final letter for the President's column for 1959. This has been an arduous but enjoyable task thrust upon your President during the past year. I only hope that you have enjoyed my humble efforts as much as I have enjoyed trying to submit to you something of timely interest.

During the past year, it has been my privilege to attend many meetings and banquets, too many to mention. However, one of the most interesting of all was an "Institution Bus Trip" early in November to the Fergus Falls State Hospital, the Walker (State Sanatorium), and the new Brainerd State School and Hospital.

The trip was sponsored by the Mental Health Policy Committee, of which Dr. Bernard C. Glueck, Jr., is chairman. It was established by law to advise the Commissioner of Public Welfare on all mental health program areas. The plan involves a series of visits to our institutions for the mentally ill, mentally retarded and tuberculous, with the intended purpose of becoming better acquainted with the patients, employes, and volunteers in these institutions, also with their treatment programs.

Those making the trip included Governor Orville Freeman, a group of State Senators and Representatives, members of the press, Morris Hursh, Commissioner of Public Welfare, Dr. Dale Cameron, Medical Director, Department of Public Welfare and his staff, myself and Dr. Bernard Glueck—a total of twenty-six. The trip was made in a comfortable bus loaned by the Cambridge State School and Hospital which was originally donated to our Sandstone State Hospital by the Tenth District American Legion Auxiliary.

We were all convinced that the hospitals are doing a very good job for patients within the limit of their funds. They could use more employes, the employes should be paid more money; but we didn't see any cases of neglect. At Fergus Falls, Dr. William Patterson is doing a wonderful job and has done so for many years, but he needs more professional help. He is aided a great deal by more than seven hundred men and women volunteers from the community who are doing an excellent service particularly in the new geriatrics unit.

At Walker, Dr. Mervyn Williams, the Superintendent, also has his troubles. That hospital is gradually becoming another mental institution. Walker is primarily for the tuberculous, but at present time there are only eighty tuberculous patients in the hospital. More than two hundred are classed as mentally ill, yet there are no psychiatrists on the Walker staff.

The new Brainerd State School and Hospital for the mentally retarded is a magnificent and luxurious institution. There are only eighty-eight patients at Brainerd at the present time, but over five hundred are expected by next summer when the various units are completed. Here the atmosphere is wonderful and particularly supplemented by more than 150 volunteers from the Brainerd area.

In conclusion, it would appear that the next session of the legislature will face a problem financially. There must be a reappraisal of top medical salaries and hospital administration salaries. It may not be more costly either. With the best staff possible and full complements of workers, the number of patients will go down.

"HEALTH" SESSION OF CONGRESS BEGINS JANUARY 4

In Roman mythology, Janus was the member of the diety with two faces in opposite directions capable of observing the past as well as the future. January, the month named in honor of this Roman god, will also mark the beginning of a crucial period in the future history of medical practice in the United States.

The second session of the 86th Congress will convene January 4, 1960. Observers close to the Washington scene predict that many of the items of unfinished business pertaining to health will receive the full treatment when Congress convenes in an election year.

A number of those observations and their possible implications were recently prepared by the Washington office of the AMA in its regular monthly summary of news. Because of the importance of this pending legislation, every physician is urged to acquaint himself with the following facts.

The U. S. Chamber of Commerce and two key Congressmen, all opponents of the so-called Forand bill, recently issued separate warnings that an all-out effort will be made to get the controversial legislation through Congress next year.

In its weekly report to members, the Chamber predicted there will be "a powerful attempt" in the next session of Congress to enact the bill (H.R. 4700) which would increase social security taxes to help pay for the cost of the Federal government providing surgical and hospital care for social security beneficiaries.

The Chamber warned that passage of the legislation would mark "a major break-through into the welfare state." It "probably would lead to a compulsory Federal program providing complete medical care for everyone," the Chamber said.

There would be "no stopping" of such a program once it got started, the report said.

The Chamber called upon communities to find orderly solutions to the problems of the aging. Otherwise, solutions "will surely be imposed from Washington," the report added.

Similar warnings were voiced by Reps. Richard M. Simpson (R., Pa.) and Thomas B. Curtis (R., Mo.), key members of the House Ways and Means Committee where the bill was put on the shelf last session.

Strong Counter Drive Urged

Rep. Curtis urged that the medical profession and other leading opponents make a strong counter-drive in an all-out effort to block passage of the bill next session. Unless there is such action, he said he would have to "regretfully" predict that legislation along the lines of the pending bill probably will be enacted in 1960.

Rep. Simpson said that H.R. 4700, and similar legislation affecting the medical profession, "make it imperative that every doctor keep informed on legislative issues before Congress." He also urged that physicians "become patriotic political forces" by giving "their informed viewpoint" to lawmakers at all levels of government.

Rep. Simpson said it "is important" that opponents of H.R. 4700 develop "appropriate alternatives" to solve the health care needs of the aged.

He promised to continue to cooperate with the medical profession to guard "against the disastrous consequences of compulsory national health insurance."

Keogh-Simpson Revival Expected

House Democratic Leader John McCormack of Massachusetts expressed hope that Congress next year will stamp final approval on another bill of particular interest to physicians. He praised the Keogh-Simpson bill (H.R. 10) as "meritorious legislation" and said it "should be enacted into law next year." The measure, which was passed by the House last spring but left hanging in the Senate Finance Committee, would provide income tax deferrals for self-employed persons setting aside money for private retirement plans.

Five-Point Government Partnership Health Program Proposed

A National Republican Committee on Program and Progress proposed a far-reaching health pro-

gram to be carried out by the Federal government in partnership with states and local governments.

Its goals would include: enlarging the capacity of medical schools so that 3,000 more doctors could be graduated each year, providing more hospital and nursing home beds, and supplementing hospital facilities with clinics, day-care centers and more visiting nurses to care for patients in their own homes.

The progress of medical science would be furthered by continued Federal support for basic medical research. But such Federal support would be given under conditions to encourage maximum non-Federal spending on medical research and to prevent "too great a diversion . . . of doctors required for the equally urgent needs of teaching and medical practice." It was estimated that expenditure of $1 billion a year—equally divided between the Federal Government and non-Federal sources—would be required by 1965.

Other recommendations included: vigorous Federal support of preventive health programs, and expansion and greater flexibility of voluntary health insurance programs.

"A free people and a free medical profession can achieve these goals with the wise support of government, without bureaucratic restrictions or interference with the physician-patient relationship which has made American health services a model for the free world," the Republican Committee stated.

The Committee proposed a five-point "partnership" program: (1) short-term Federal aid for construction of medical school buildings, (2) changes in the present hospital construction program to encourage renovation and repair of outmoded hospitals, (3) Federal guarantees for mortgages to finance construction of private nursing homes on a basis assuring high standards of quality in construction and operation, (4) encouragement of construction of diagnostic and outpatient facilities in rural areas and the building of mental health clinics, and (5) Federal aid to cities "in more effective planning and coordination of health services."

PROBLEMS OF AGED AND AGING AIRED IN SENATE SPEECH

Unless Americans recognize and meet the problems of elderly citizens, the cost to the Nation in years ahead will be "too fantastic to contemplate," according to Senator Pat McNamara (D. Mich.), Chairman of the Senate Subcommittee on Problems of the Aged and Aging.

In a speech to the Senate, McNamara cited the rapidly growing population of elderly persons and said that "if medical progress continues, there is no basic reason why human beings cannot live to the age of 125.

"With this dramatic trend, today's problems of aging will seem like minor ripples as compared with the floods of tidal proportions to come," he said.

His speech was in the nature of a progress report on the work of the Subcommittee since it was created by Senate Resolution in January. Extensive hearings have been held in Washington, and following the adjournment of Congress, the Subcommittee will conduct on-the-spot hearings in cities across the Nation.

Life Expectancy Increases

McNamara said that life expectancy in the United States today is about seventy, compared with forty-eight only a little more than fifty years ago. Another forty years is expected to see life expectancy rise to 82. Today there are more than 16 million persons over sixty-five, while there were only 3 million in 1900.

"If we continue to relegate old people to the sidelines—financially, medically and socially—the financial burden to this country just in terms of institutions for the aging will be too fantastic to contemplate," Senator McNamara said.

"We have made it possible for more people to live into the so-called 'golden years' but without adequate incomes, health care, housing and without a recognized role in the community life of the Nation."

Financial Problems of Aging Cited

Senator McNamara said the primary issue facing the aging today is how to maintain a decent American standard of living on a heavily reduced income.

He pointed out that official estimates show an elderly couple needs at least $2,300 a year to live in an urban center in modest fashion. Yet, he said, the average couple on Social Security receives less than $1,500 a year.

"The income of a large proportion of the 16 million Americans over sixty-five ranges from

mere subsistence to desperation and despair," he said.

"Today, benefits from Social Security are apparently not intended to cover most of the living expenses of retired men and women. And we have only begun, in some areas of employment, to create adequate private pension arrangements."

Alternatives Must Be Explored

"In one way or another, a price will have to be paid to meet this growing problem, and both the public and private sectors of America must begin now to explore the alternatives open to us."

Senator McNamara said the problem of health in later years also was a matter of extreme importance and noted that one committee witness had described it as "just as much a public health problem as Strontium 90 in milk or polio in children."

According to Senator McNamara five major points emerged from discussion of the health needs of the elderly.

First: Medical care needs to be reorganized so as to prevent deterioration rather than to merely repair damage. *Second:* Miracles have been wrought in so many cases in the rehabilitation of stroke victims, heart patients, and other sufferers of crippling diseases that an investment in rehabilitation will pay off many times over, not only in dollars, but in human welfare. *Third:* Aged persons in this country require about two and one-half times as much hospital care as the younger age groups. *Fourth:* The large majority of older people in this country do not have adequate hospital and surgical insurance, although in recent years there has been an increase in the number who purchase some kind of voluntary health insurance. Too much of this is inadequate as to benefits, as well as too expensive. *Fifth:* The biggest problem in the medical field for the elderly is the financing of medical care out of a reduced and often merely subsistence income. The subcommittee was urged to study carefully the proposed solutions in this critical field of financing medical costs.

"Over the past decade, there has been a slow but steadily growing recognition of the aging challenge," noted Senator McNamara.

"We hope that the work of this Subcommittee will lay the foundations for a systematic consideration by the Senate of the needs of our older citizens and the contributions they can continue to make to the Nation.

"There is no panacea for these problems, but we do intend to deal with the human values and the proper public policies designed to add life to years, not merely years to life."

HOSPITAL STAYS SHOW POST-WAR DECLINE

Seven out of every ten persons admitted to hospitals stay seven days or less, according to the Health Insurance Institute.

Some 88 per cent of all admissions stay fourteen days or less and 96 per cent stay thirty days or less, the Institute added in its report on a U. S. National Health Survey of hospitalization in the nation over a twelve-month period.

Several studies have indicated that the average length of hospital stay per patient has declined considerably in the post-war years. Programs of all health insurance organizations have been expanded to meet the needs of modern hospital services.

A recent survey of 188 insurance companies disclosed that all provided policies with benefits for more than thirty days of hospitalization, and that 174 companies had policies with benefits for ninety days or more.

More than 123 million Americans had hospital expense insurance at the end of 1958. Insurance companies, Blue Cross, and independent health care plans paid benefits of $2.6 billion in 1958 for hospital care alone, out of a total of $4.7 billion in health insurance benefits.

Women Lead in Hospital Admissions

The National Health Survey revealed that women were hospitalized more frequently than men but stayed for a shorter period of time. Women were hospitalized at a rate of 123 per 1,000 to 74 per 1,000 among men, but stayed about seven days on the average to eleven days among men.

The higher rate of admission among women was attributed generally to maternity which probably also played a significant part in the surprising finding that the highest hospitalization rate by age group came in the fifteen to twenty-four bracket where 137 out of every 1,000 experienced a hospitalization episode. The lowest rate was among children under fifteen where fifty-three out of every 1,000 were hospitalized.

Midwest Tops Hospitalization Rate

By region of the United States, the highest hospitalization rate was in the Midwest, where 105 of every 1,000 persons entered the hospital during the year. The West had a rate of 100, the Northeast followed with ninety-seven, and the South had the lowest, ninety-five.

Of all admissions to the hospital during the year of the study, six out of ten were surgically treated and four of ten were not surgically treated. Surgical patients stayed, on the average, 7.5 days while non-surgical patients stayed 10.3 days.

The study showed that ninety-nine out of every 1,000 persons in the United States were hospitalized during the year, and that they stayed in the hospital an average of 8.6 days.

HOSPITAL COSTS UP

According to the American Hospital Association, the average cost per patient day in the nation's non-federal short-term hospitals has risen steadily in the post-war years. Below is the average cost by year:

Year	*Average Cost Per Patient Day*
1949	$14.33
1950	15.62
1951	16.77
1952	18.35
1953	19.95
1954	21.76
1955	23.12
1956	24.15
1957	26.02
1958	28.17

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

HENNEPIN COUNTY MAN GIVEN ONE-YEAR PROBATIONARY TERM FOR REPRESENTING HIMSELF AS DOCTOR

On November 2, 1959, Robert P. Selisky, 35, 5260 Hampshire Ave. N., Crystal, Minnesota, was sentenced by the Hon. John A. Weeks, Judge of Hennepin County District Court, to a term of one year in the Minneapolis Workhouse pursuant to the defendant's plea of guilty, entered on September 30, 1959, to an information charging him with violating the basic science law by attaching the word "doctor" to his name with the design of indicating that he was engaged in the practice of healing. However, after sentencing Selisky the Court stayed the execution of the sentence and placed him on probation for a period of one year. When questioned by the Court prior to being sentenced, Selisky stated that he is a high school graduate and has completed three years of college. He added that he is presently employed by a Minneapolis musical records firm. After the questioning of the defendent was completed, his attorney made a plea for leniency on the grounds that Selisky is not addicted to dexedrine but only used it as a "crutch" to enable him to meet some emotional crisis such as financial trouble or marital difficulties.

The defendant was arrested on August 30, 1959, by officers of the St. Louis Park Police Department, after he had telephoned the Mike Zoss Drugs, 8024 Minnetonka Blvd., saying that he was Dr. Norris and ordering 100 dexedrine tablets for an alleged patient. Because neither the name of the patient nor the name of the doctor could be verified by the pharmacist the authorities were contacted which resulted in Selisky's arrest after he arrived at the drug store and paid for the tablets. In a written statement taken from the defendant subsequent to his apprehension he admitted that he had previously been arrested in Minneapolis for attempting to purchase drugs in a similar manner. When asked his reason for wanting to obtain dexedrine tablets Selisky replied that he had been addicted to these pills from 1942 to 1945 and that he has been endeavoring to get rid of the habit since that time. When the Minnesota State Board of Medical Examiners was contacted in reference to the matter, a representative of the Board signed a criminal complaint, issued by the Hennepin County Attorney's office, charging Selisky with violating the basic science law, which is a gross misdemeanor.

The defendant has two prior convictions, both being in the Municipal Court of the City of Minneapolis. On September 1, 1954, Selisky was held for police officers at the point of a gun by a Minneapolis man who claimed that the suspect had knocked down his porch railing. Although Selisky was incoherent and acted as though he had been drinking, no odor of alcohol could be detected from his breath and he later admitted to the police that he had been taking seconal and benzedrine. On the following day the defendant was convicted by the Court of the offense of disorderly conduct whereupon he was sentenced to sixty days in the Minneapolis Workhouse, the sentence being stayed and the defendant placed on probation for one year. However, on September 18, 1954, Selisky was again arrested, his probation was revoked and he was committed to the workhouse. On August 26, 1956, Selisky was arrested on a charge of violating the City Drug Ordinance in Minneapolis. The defendant was convicted of that offense and Judge Lindsay G. Arthur sentenced him to a one-year term in the workhouse but stayed the execution of the sentence for the same period of time. Selisky holds no license to practice any form of healing in the State of Minnesota and has not taken training in medicine.

HIGH WCCO LISTENERSHIP CONTINUES

"Doctor's House Call" mail response to the five-minute radio program featuring Dr. James Rogers Fox continues high.

The same is true for "Your Health," heard each Sunday morning at 8:05 a.m. on WCCO. This program features a discussion of timely health topics between Doctor Fox and Maynard Speece.

Recently offered to "Your Health" listeners were "Questions and Answers on Arthritis" by the Arthritis and Rheumatism Foundation, and "Teaching Johnny To Swim" published by the American Red Cross. In each instance mail requests for individual listeners topped the one thousand mark. Requests for these materials were processed by the staff of the Minnesota State Medical Association.

MOVIE TAGS MEDICAL ASSISTANT AS "DOCTOR'S PR AMBASSADOR"

The key role played by the physician's medical assistant in creating good public relations is emphasized in a new film now available for showings to medical societies and medical assistants groups.

Entitled "First Contact," the twenty-six minute dramatic color film shows the mistakes a new office assistant can make unless she is properly trained for her job and points out that medical assistants groups provide opportunities for increasing on-the-job efficiency.

Dr. F. J. L. Blasingame, Executive Vice President of the American Medical Association, who appears in the film, says the medical assistant is a valuable ally in providing better patient care. Says Doctor Blasingame:

"The medical assistant is the doctor's public relations ambassador—often she has first contact with the patient. Her understanding of good doctor-patient relations and her practice of the techniques that create good will are manifold in their value to her physician and the medical profession.

"The professional medical assistant can make it possible for the doctor to concentrate his time on the scientific side of his practice."

In the film Doctor Blasingame comments on the growth of a new national organization, the American Association of Medical Assistants, dedicated to educational improvement and medical profession cooperation. The AMA passed a resolution commending the aims and objectives of the AAMA in December, 1956.

"First Contact" was premiered before five hundred members of the American Association of Medical Assistants holding their third national convention in Philadelphia, October 16. Prints of the 16 mm. film are available to medical societies for showings through AMA's Department of Medical Motion Pictures and Television and to medical assistants groups through the headquarters of the American Association of Medical Assistants in Chicago at 510 North Dearborn Street.

The film, produced for AAMA in cooperation with AMA as a special service of Wyeth Laboratories, also can be obtained by writing directly to the Wyeth Film Library, Box 8299, Philadelphia 1, Pennsylvania.

HAVE YOU HEARD THE NEW "DOCTOR, TELL ME"?

Public health education in Minnesota assumed a new dimension when the new five-minute "Doctor, Tell Me" radio series sponsored by the Minnesota State Medical Association was inaugurated during the week of October 25.

Nineteen radio stations throughout the state of Minnesota have adopted the new format which features Doctor James Rogers Fox answering questions as asked by Miss Audrey June Booth. A number of stations have already expressed their approval of the new series.

Eight stations are continuing to schedule the traditional fifteen-minute program series heard once each week. Many of the stations participating in this project have scheduled "Doctor, Tell Me" for the fourth consecutive year. Because the demands upon the broadcasting industry for public service time are many, those stations who continue to schedule "Doctor, Tell Me" are indeed worthy of a word or note of thanks.

Physicians and county medical societies are urged to extend their appreciation to radio stations within their area who schedule "Doctor, Tell Me." The future of "Doctor, Tell Me" could depend upon your simple thank you.

Stations which have scheduled the new Monday through Friday "Doctor, Tell Me" series are:

Alexandria	KXRA	10:50 a.m. Monday through Friday
Benson	KBMO	Right before signoff news at sunset
Brainerd	KLIZ	2:55 p.m. Monday through Friday
Crookston	KROX	4:05 p.m. Monday through Friday
Detroit Lakes	KDLM	2:25 p.m. Monday through Friday
Duluth	KDAL	6:30 p.m. Monday through Friday
Ely	WELY	6:05 p.m. Monday through Friday
Fairmont	KSUM	
Faribault	KDHL	6:55 p.m. Monday through Friday
Litchfield	KLFD	9:25 a.m. Monday through Friday
Little Falls	KLTF	9:55 a.m. Monday through Friday
Mankato	KYSM	6:05 p.m. Monday through Friday
Marshall	KMHL	10:10 a.m. Monday through Friday
New Ulm	KNUJ	10:35 a.m. Monday through Friday
Pine City	WCMP	3:02 p.m. Monday through Friday
Red Wing	KCUE	9:15 a.m. Monday through Friday
Redwood Falls	KLGR	6:10 p.m. Monday through Friday
St. Cloud	KFAM	3:30 p.m. Monday through Friday
Windom	KDOM	4:30 p.m. Monday through Friday

These stations have scheduled the fifteen-minute "Doctor, Tell Me" program once each week:

Albert Lea	KATE	7:00 p.m. Wednesday
Eveleth	WEVE	5:15 p.m. Sunday
Grand Rapids	KOZY	5:15 p.m. Saturday
Pipestone	KLOH	4:30 p.m. Sunday
Thief River Falls	KTRF	7:00 p.m. Sunday
Willmar	KWLM	4:45 p.m. Sunday
Winona	KWNO	
Worthington	KWOA	4:30 p.m. Sunday

Medical Legal Opinion

● *The purpose of this section entitled Medical Legal Opinion is to publish news of recent litigation concerning medical practice as well as to cite past actions and opinions of the Court in medical legal matters as a means of refreshing our knowledge of such procedures.*

GRANGER v. ADSON et al, No. 29476,
Supreme Court of Minnesota, November 3, 1933

Syllabus by the Court

1. The plaintiff, a layman, in conducting a "health audit" for a fee for which he furnished his subscribers with the results of urinalyses and blood pressure tests, and either himself advised, or passed on to the subscriber advice from the pathologist who made the urinalyses, as to whether the results showed a normal or abnormal state of health and whether the subscriber should see a physician, in some cases advising as to diet, exercise, and habits, was practicing medicine unlawfully in violation of section 5717, Mason's Minn. St. 1927.

2. In so doing he is practicing the science of healing in violation of Mason Minn. St. 1927, section 5705-1, which defines the science as including the diagnosis or analysis of the condition of human health.

3. Plaintiff's contract with his pathologist was illegal and in violation of statute and the public policy of the state.

Appeal from District Court, Hennepin County; Frank E. Reed, Judge.

Action by John Granger against A. W. Adson and others, individually and as members of the State Board of Medical Examiners. From an order sustaining a demurrer to the complaint, plaintiff appeals.

Affirmed.

Thompson, Hessian & Fletcher and Carleton F. Boeke, all of Minneapolis, for appellant.

Harry H. Peterson, Atty. Gen., and F. Manley Brist, Sp. Asst. Atty. Gen., for respondents.

LORING, Justice.

This is an appeal from an order sustaining a demurrer to plaintiff's complaint in an action to enjoin the defendants from interfering with a contract which plaintiff had with a Dr. Grave. The complaint alleges that plaintiff, who is a layman, conducts what is termed a "health audit" in the city of Minneapolis. For a fee of $10 per year, he contracts with his "subscribers" to furnish four urinalyses and a blood pressure test each year. The urine samples are sent in by mail, as a general rule, and plaintiff then turns them over to Dr. Grave, a pathologist with whom he has a contract to furnish the results of the analyses to him. According to the plaintiff, if an analysis shows serious abnormal condition he advises his subscriber to consult a competent physician; but if the abnormality is slight he advises him in regard to proper diet, habits, and exercise, should the report of Dr. Grave advise such. Plaintiff's complaint specifically denies that he is practicing medicine or that the conduct of a health audit business consists of the practice of medicine. The defendants, who comprise the state board of medical examiners, advised Dr. Grave that plaintiff was engaged in the practice of medicine contrary to the laws of the state of Minnesota, and at once to desist from making urinalyses for the plaintiff on the ground that it was illegal for Dr. Grave to furnish plaintiff with the results thereof for the benefit of the plaintiff's subscribers. He accordingly desisted, and this action followed.

1. It is the contention of respondents that Granger was engaged in the practice of medicine contrary to the provisions of section 5717, Mason's Minn. St. 1927, and that he was engaged in the practice of healing as defined by the basic science law, Mason Minn. St. 1927, section 5705-1. It is alleged in the complaint:

> "It is true that in some cases where an abnormal condition is not indicated but certain minor disturbances appear, plaintiff, after consultation with the pathologist, and repeating the advice given him by the pathologist, advises the subscriber as to certain improved habits of either diet, exercise, or living. Under no circumstances does plaintiff ever advise the taking of any medicine or any treatment, but suggests to all subscribers whose reports are repeatedly abnormal that they should consult their own physician. *** That a urine analysis and blood pressure test furnish a convenient, reliable and accurate indication of the state of a person's health."

In our opinion, advising the subscriber for a fee as to certain improved habits of diet, exercise, or living, although not accompanied by any medical prescription or treatment, is a violation of section 5717. State v. Edmunds, 127 Iowa, 333, 101 N.W. 431; Heintze v. State Board, 107 N.J. Law, 420, 153 A. 253. Diet, exercise, and mode of living are agencies for the relief of disease; indeed, they are the only known relief or treatment of some diseases. It further appears that the urinalyses and blood pressure tests are important as indicating the condition of a patient's health, and when an abnormal condition is indicated the opinion of the pathologist is passed on by the plaintiff to his subscriber.

In his complaint, the plaintiff sets out some twenty-two items whose presence, absence, or quantity must be considered in determining the result of the analysis. The analysis and the test form a basis for a diagnosis. Necessarily, the question of whether the analysis results in indications showing normal or abnormal conditions is a matter of professional medical opinion. Deductions must be drawn from the result of the analyses, and these deductions are of value only when made by a medical man. It cannot be otherwise. The pathologist is, of course, a licensed physician, and in this case is said to be an expert in his line. Obviously, if he were in direct contact with the subscriber as a patient, he would be practicing medicine in doing exactly what the plaintiff hired him to do. The results of his work the plaintiff passes on to his subscribers. It is settled law in this state that:

"The science of diagnosing human diseases and human ailments has come to be a distinct branch or department of the medical profession; the diagnostician limiting his efforts to a discovery of the disease or ailment from which a patient may be suffering, its character and location, leaving the treatment thereof to some other physician or surgeon. This is a matter of common knowledge. And it requires no discussion or argument to demonstrate that the physician who thus applies his learning and energies is performing a highly important duty of the profession, and is engaged in the practice thereof, though he prescribes no drug and administers no specific treatment." State v. Rolph, 140 Minn. 190, 194, 167 N.W. 553, 554, L.R.A., 1918D, 1096.

If Dr. Grave was practicing medicine in what he did and in determining for the plaintiff whether the condition of the urine was normal or abnormal, then, in our opinion, the plaintiff was practicing medicine when he passed on to his subscribers the result of the analyses and the advice of the pathologist. It was as much practicing medicine for the plaintiff to engage Dr. Grave to do this for him as it would have been if he had attempted himself to perform these analyses, as he in fact did in the case of the blood pressure tests. To pass on to his subscribers advice as to whether or not the tests indicated a normal or abnormal condition, and whether or not the subscriber should consult his physician or be content with the advice which plaintiff might give in regard to diet, exercise, or mode of living, was practicing medicine. In Re Disbarment of Otterness, 181 Minn. 254, 232 N.W. 318, 73 A.L.R. 1319, we said that a corporation or layman could not indirectly practice law by hiring a licensed attorney to practice law for others for the benefit or profit of such hirer. We are just as firmly convinced that it is improper and contrary to statute and public policy for a corporation or layman to practice medicine in the same way. The obligation of Dr. Grave under his contract was to plaintiff, not to the subscribers. Plaintiff might engage anyone to perform these analyses. What the law intends is that the patient shall be the patient of the licensed physician, not of a corporation or layman. The obligations and duties of the physician demand no less. There is no place for a middleman.

We see nothing in this to prevent life insurance companies from furnishing gratuitous examinations to their policy-holders. They charge no fee, and make the examination in furtherance of reduction of hazard. Neither do we see any objection to the employment by physicians of technicians and other experts, the results of whose work the physicians interpret as a help to diagnosis.

2. Mason Minn. St. 1927, section 5705-1, defines the practice of healing as including the diagnosis or analysis of the condition of human health. As above stated, the plaintiff has alleged in his complaint that the analyses and tests which he furnishes his subscribers constitute a convenient, reliable, and accurate indication of the state of a person's health. It is so obvious that what the plaintiff does in this regard is practicing healing within the provisions of the statute quoted that it is unnecessary further to discuss that subject.

3. It follows that the contract between the plaintiff and Dr. Grave was in furtherance of plaintiff's violation of these statutes. It was illegal, against public policy, and void, and no injunction will lie to prevent interference therewith.

The order is affirmed.

Minnesota Blue Shield—Blue Cross

Minnesota Blue Shield has provided benefits for the delivery of over 150,000 new Minnesotans. The number of obstetrical claims paid by the Plan from its beginning in 1947 through September, 1959, totals 158,646.

Obstetrical benefits provided by Blue Shield as of September 30, 1959 total over $9,629,000. This figure is equal to an average obstetrical payment of slightly more than $60. For approximately the first five years of operation the Plan A obstetrical allowance was only $50. During 1953 this benefit was increased to $60 and in 1954 Plan B was made available with an obstetrical allowance of $100. The average obstetrical payment has increased steadily as the number of Plan B family contracts has increased.

The number of obstetrical services paid by Blue Shield as of September 30, 1959 is equal to approximately 18 per cent of the total number of participant subscribers enrolled as of the same date, 871,795.

During the first nine months of this year Blue Shield paid $1,153,426 for 17,174 obstetrical claims, an average of over $67 per claim.

Ten months have passed since Minnesota Blue Cross started notifying members as to the intent of the Blue Cross contract as related to routine physical examinations or diagnostic studies. To date, all non-group members have been notified as to the exclusion and all group members will be notified by December 1, 1959.

Statistics to date indicate that clarification of the intent of Blue Cross benefits as related to diagnostic and physical examinations with doctors and members has apparently been successful in curbing a certain amount of needless use of Blue Cross contracts. This in turn has resulted in the reduction of the number of persons hospitalized per 1,000 Blue Cross contracts in effect.

A significant stablization in the number of services provided occurred in the areas of medical care. This is the category in which Blue Cross provides diagnostic and physical examinations of members hospitalized for conditions of illness or injury on an in-patient basis.

Richard T. Crist, president of Minnesota Blue Cross, said, "Even though the percentage of decrease might not appear to be too great, such a favorable trend indicates that we are going in the right direction of our objective . . . that of attempting to stabilize rates for Minnesota Blue Cross members."

Crist further explained that success in curbing needless use of Blue Cross benefits was largely a result of cooperation on the part of doctors and Minnesota Blue Cross members. "Several thousand personal phone calls were made to doctors during the first nine months of 1959, at which time we requested clarification as to the nature of the diagnosis and hospitalization," Crist said. "In almost 100 per cent of the cases, the doctors were extremely helpful."

Crist said that "Blue Cross owes a 'thank you' to the members and doctors of Minnesota for cooperating in what apparently has been a successful project . . . a project though apparently successful did not result in denying Blue Cross hospital benefits to those who were sick and needed care."

Crist also pointed out that reserves for contingencies and future hospital care of members now exceed four million dollars and operating expense for the first nine months of 1959, hit an all time low of 4.6 per cent of subscriber income.

HEART ASSOCIATION BEGINS DIRECT PUBLICATION OF JOURNALS

Direct publication by the American Heart Association of its two scientific journals, *Circulation* and *Circulation Research*, will begin with the January, 1960, issues. The journals were previously published by a private publishing firm.

Under the new arrangement, *Circulation* will regularly feature symposia on a broad range of subjects relating to cardiovascular diseases. The first symposium, consisting of various papers on the subject of congestive heart failure, will be carried in the January, February and March, 1960, issues of the journal.

As in the past, other sections of *Circulation* will be devoted to original articles and practical reviews by leading cardiologists, abstracts of significant international contributions to cardiologic problems, book reviews and news notices of particular interest to clinicians and cardiologists. Issued monthly by the Association since 1950, *Circulation* is edited by Dr. Herrman L. Blumgart of Boston, Professor of Medicine, Harvard University.

Additional symposia for publication in forthcoming issues are planned on coronary heart disease, surgery in acquired valvular disease, angina pectoris, myocardial infarction, degenerative cerebral vascular disease, cardiac surgery, regulation of the cardiovascular system in health and disease, and recent developments in supplementary diagnostic techniques.

Circulation Research is the only publication devoted exclusively to reports on fundamental research studies as they apply to the broad field of cardiovascular medicine and surgery. Inaugurated by the Association in 1953, the journal is issued bimonthly and edited by Dr. Carl F. Schmidt of Philadelphia, Professor of Pharmacology, University of Pennsylvania Medical School.

Committee Action

COMMITTEE ON PULMONARY DISEASES

Minutes of Meeting
June, 1959

Dr. John F. Briggs, in opening the meeting, announced the subject for discussion as "Pulmonary Function Studies," to be presented by Dr. Robert Rossing and Dr. Ward Fowler.

Dr. Rossing defined the scope of the evening's discussion. He and Dr. Fowler had decided to cover the subject in two meetings, with the first meeting to include the basic physiology of pulmonary function tests and the testing technique. The second meeting will include more direct clinical application and interpretation of these tests.

Dr. Rossing showed several slides and gave credit to the book entitled "The Lung" by Julius H. Comroe, Jr., M.D., et al, which he had used extensively for slide material. He highly recommended this book to the committee members interested in a study of pulmonary physiology and its application.

The first slides outlined the four primary lung volumes as (1) tidal volume; (2) inspiratory reserve volume; (3) expiratory reserve volume; and (4) residual volume. He discussed the various terms denoting the four capacities of the lung, the best known of which is the "vital capacity"—the total amount of air that can be expelled from the lungs by forceful effort following maximal inspiration. He defined the "functional residual capacity" as the amount of air remaining in the lung at the end of an expiration. Even at the end of maximal expiration, Dr. Rossing explained, a certain amount of air which is in the lung cannot be expelled. Lung volumes can be measured by a spirometer and some can be measured by direct methods. However, the measurement of functional residual capacity usually is not incorporated as part of a routine clinical pulmonary function evaluation.

Dr. Rossing also discussed "dead space"—the amount of air moved with each breath which does not come into effective contact with alveoli and pulmonary capillaries; it is wasted ventilation. Types of respiratory dead space according to one of the slides shown by Dr. Rossing, are found in: conducting airways—"anatomic" dead space; alveoli with no blood and ventilation in excess of blood flow—"physiologic" dead space.

Dead space was originally measured in cadavers. The measurement of anatomic dead space in a living individual is usually done with a nitrogen meter. The patient takes a single breath of oxygen. Then he exhales into a nitrogen meter. The volume of air is measured up to the point at which nitrogen first appears. Measurement of physiologic dead space depends on comparing the carbon dioxide content of expired air with the carbon dioxide content of alveolar air. Dead space, Dr. Rossing went on, does have some real clinical significance. Sometimes patients with marked respiratory insufficiency are unable to take deep breaths. At times, tracheotomy is advisable to reduce the dead space.

Dr. Rossing then brought up the question, "What does the lung do?" Lung function may be broken down, for terms of discussion, into four activities:

1. *Ventilation*—The actual transport of air into the lungs.
2. *Distribution*—The partition of air so that each segment (and, ideally, each alveolus) obtains an equitable share of ventilation.
3. *Diffusion*—The transport of oxygen and carbon dioxide across the alveolo-capillary membrane from alveolus to capillary blood.
4. *Circulation*—The process of supplying each pulmonary capillary with an equitable share of blood flow.

Dr. Rossing said that pulmonary ventilation involves work, and an elaborate set of muscles has been provided us. The work of breathing that must be done can be defined as force times distance, or as pressure times volume. His next slide, illustrating the elastic work done in the lung, showed the difference in force needed to move a block (which was attached to a wall by a spring) when the block is resting on a frictionless surface, and when the block is resting on a rough surface. Additional work is needed to overcome friction. Similarly, there is friction in the lungs—primarily of air as it passes through the airways. There is also tissue friction within the lung itself. The two types of work have been described by the physiologist as pulmonary compliance and pulmonary resistance.

Measurement can be made of the elastic properties of the lung. It is defined as the increase in volume which results from each unit change in pressure. Measuring the volume of air which enters the lung with each unit of pressure measures the lung's compliance.

A patient with a fixed maximum respiratory

force, as his compliance decreases, will be able to effect less of a volume change than a patient with a more compliant lung. By applying this same force, as his resistance increases, he will be able to move air more slowly. Therefore, we measure the amount of air which the patient can move with a single breath and the rate at which he can do it.

A patient with pulmonary fibrosis, for instance, has reduced pulmonary compliance and can move a good deal of air less than the average patient. The tests which are available to measure specific resistances to breathing are useful in recognizing conditions in which there is a reduction in pulmonary compliance.

One of the succeeding slides showed spirograms of normal patients and patients with pulmonary fibrosis, asthma, and emphysema. The patient with asthma took ten seconds to accomplish what the normal patient could do in three or four seconds. By measuring the time component, the doctor knows how rapidly the patient can move air. It is also important, Dr. Rossing added, to measure total vital capacity.

Tribute was paid to Dr. Myers and the charts he developed which are still being used today. Dr. Myers was one of the first to call attention to the importance of measurement.

The measurement of time to be used. Dr. Rossing went on to say, can be one second, and the volume of air expired in the one second can be expressed as a ratio to the patient's total vital capacity. Dr. Fowler has recently stressed the measurement of the mid-expiratory flow rate. Another measurement used is the early flow rate, in which an attempt is made to estimate peak flow rate right at the beginning of expiration.

The important thing, as brought out by Dr. Rossing, is that some sort of time estimate be made as to how air comes out of the lung. This type of measurement enables the doctor to classify difficulties as restrictive and obstructive. Restrictive difficulties are those in which the total vital capacity is primarily affected. This can be related to a reduced compliance. Obstructive difficulties are those connected with asthma and emphysema, where the essential difficulty is the patient's inability to force air through the obstructed airways.

After study of total vital capacity, Dr. Rossing said, people begin to ask questions about the relative ventilation of the two lungs. It becomes especially important when the patient is being considered for surgery, in which one lung or a portion thereof must be removed. This gives rise to bronchospirometry.

Dr. Sumner S. Cohen, being called on for a discussion of the technical factors involved in bronchospirometry, stated that it is developed as a means of determining the relative part each lung is contributing to the total breathing capacity. This is helpful under many conditions particularly with the recent extensive development of thoracic surgery. Dr. Cohen stated that sometimes it is essential to know the relative part contributed by each lung—in cases of bilateral disease or in patients in the older age group.

Bronchospirometry is done by introducing a double barreled catheter, similar to bronchoscopic tubes. It can be done with the patient in an upright or supine position. Dr. Cohen said that the tube is introduced with the patient in an upright position. Two balloons are inflated—all the air from the left side goes through one part of the tube. That is then connected with a double spirometer. The resistance factor has been removed, as far as possible. The resulting graph can subsequently be interpreted. Dr. Cohen emphasized that this is primarily to give the relative function of the two sides and is not a good method of getting total actual values. It is done under abnormal conditions and does not represent what the patient can normally do. At present, he added, Carlen's tube is used because resistance is not so great.

Dr. Cohen showed a slide illustrating the type of tracing obtained by bronchospirometry, indicating measurement of air flow of the two lungs in relation to each other. The slide was done on a patient who was being checked because of her requirement for bilateral resection. On initial testing, she had 60 on the right and 40 on the left. It is usually true, Dr. Cohen indicated, that the right is a little better than the left.

Dr. Cohen stated that during his training, it was believed that the patient should lie on the side to reduce the movement of one lung. However, it has now been shown that ventilation is improved on the side on which the patient is lying.

Dr. Ward Fowler, in presenting his part of the program, discussed the oxygen hemoglobin dissociation curve and stated that the principal function of the lung is to exchange oxygen and carbon dioxide. The over-all rates at which the lungs do this are not often issues, because the problem is the supply of oxygen. If oxygen is not supplied to the brain, a person is dead in five minutes. Under ordinary circumstances, as long as people are alive and functioning, the over-all supply of oxygen is adequate. The problem in evaluating pulmonary efficiency is the efficiency with which this process is accomplished—the level at which these gases are maintained.

Dr. Fowler went on to say that the end result of taking in oxygen is getting oxygen into the blood for transport to the tissues. He then discussed hypoxemia—the lack of oxygen in the blood. Since blood is similar in all arteries, any blood can be examined to see what the levels of oxygen are. The usual clinical evaluation of hypoxemia is by the observation of cyanosis. Nor-

mally, it is necessary for most observers that saturation be down from the normal 95 per cent to 80 some per cent before cyanosis can be detected visibly. Visible cyanosis is a very advanced problem basically in terms of how efficient the lung is. There is a more efficient procedure to find out how well the lungs are exchanging oxygen. This becomes technically difficult, however; there is no procedure simple enough to be done in office practice. Measuring tension, Dr. Fowler pointed out, is quite difficult. Another approach is the measurement of oxygen saturation. This must be done very accurately. Saturation is the content of oxygen over the capacity of the hemoglobin. One hundred per cent saturation means that the hemoglobin contains all that it possibly can contain. This requires arterial blood, and the arterial puncture, according to Dr. Fowler, is not particularly difficult. Blood can then be analyzed for oxygen, and this process is within the realm of any laboratory.

Other methods used to determine oxygen saturation are manometric or photometric techniques—such as the spectrophotometric. These are becoming increasingly available in hospital laboratories. All require direct samples of blood from an artery. There are also bloodless methods —one of which works on the principle of reflected light.

Dr. Fowler referred to the ear-oximeter developed by Dr. Wood, which has the advantage of continuous readings. However, the initial cost is high and the technical maintenance almost prohibitive, unless it is needed eight hours a day every day.

Another problem discussed by Dr. Fowler was the measurement of the level of carbon dioxide. There is no simple, easy way of going about this in terms of measurement, he stated. There are bloodless methods which Dr. Fowler believes will be the methods of the future. If one has the proper means of analyzing how much carbon dioxide is in the expired air, it is easy, he said. There are machines on the market—such as the infra red analyzer. This machine is not much more difficult to operate today than an electrocardiograph. It will run constantly for several years before needing maintenance. However, Dr. Fowler added, it is fairly expensive. When used on a patient with emphysema, unfortunately, the particular sample of air which is obtained when the patient breaths out, is not the sample the doctor wants. The sample is from the overventilated part of the lung. Serious mistakes can be made if this is not recognized.

A procedure which a number of laboratories all over the world are working on is adapting the infra red analyzer to the old procedure of rebreathing.

The usual method of measuring carbon dioxide is by plasma combining power, which was first introduced by Dr. Van Slyke. This method is still used by the medical profession, although abandoned by Dr. Van Slyke. One is able still to get a fairly good answer without serious technical difficulties.

When the carbon dioxide combining power is normal, Dr. Fowler added, there is neither acidosis nor alkalosis. With experience and with understanding, the carbon dioxide combining power can be very useful, and the doctor can determine a great deal about acid-base balance. He believes the bloodless methods will come into wide clinical use.

In summarizing his discussion, Dr. Fowler stated that as yet nothing basically new in the field has appeared since recognition of CO_2 combining power. However, we are now moving quite rapidly. There are some methodologies suitable now for large institutions with many patients. Many of Dr. Fowler's clinical colleagues are ordering these tests on a routine basis for their patients. He added that Dr. Myers no doubt had a very good picture of the whole area of pulmonary function studies. Dr. Fowler believes that the lungs are as important as the kidneys or any other part of the body. In the last ten years, there has been a revival of interest in the lung here and all over the world. He attributes this increased attention to better chest methods in many areas—better thoracic surgery, for example. It becomes necessary for the doctor to make decisions involving lung surgery. There has been an increasing interest in the diseases of the lung as people get older. He added that it is regrettable that no one in the United States has an accurate record of the incidence of emphysema. This is not a rare disease. Dr. Fowler likened it to tuberculosis as it was regarded fifteen to twenty years ago. Although the etiology of pulmonary emphysema is not known, this does not mean, Dr. Fowler said in conclusion, that one must cease trying to identify it early and attempting to use the therapeutic measures which are available.

Dr. Briggs called on *Dr. Baldry* for comments on the status of chronic bronchitis in England. In Dr. Baldry's opinion, there is a difference in definition of that disease between our two countries. He is sure there is a lot of chronic bronchitis in America, even if it is not known by that term. He went on to say that he believes the greatest thing they have at the moment to stop chronic bronchitis in Great Britain is to stop people from smoking. However, he added, that cannot be the whole answer. There are atmospheric problems in England—such as the humidity and pollution of the air. They are working on the problem of a cleaner atmosphere.

Dr. Briggs then called on *Dr. J. A. Myers* for comments on the early research in pulmonary diseases. Dr. Myers referred to a critique written

by John Hutchins of England in 1847. He also discussed the contribution of Ernest Graham during World War II. Many soldiers were dying from flu pneumonia, and Dr. Graham was appointed Empyema Commission Chairman. Under his direction, open surgery on the chest was restricted to those patients whose vital capacity was at a satisfactory level.

Dr. F. F. Callahan mentioned his experiences during World War I. There was a tremendous amount of empyema, and it was standard procedure at that time that if fluid was found in the chest, the physician would operate.

Dr. Ralph West was called upon to comment on the subject from the veterinary standpoint. He said there was little on which he could report since the new procedures for studying pulmonary functions had not been applied in his field. Dr. Fowler questioned Dr. West about the relation of veterinary medicine to the problem of pulmonary emphysema in human beings. Dr. Fowler mentioned a research conference on pulmonary emphysema held in Colorado last summer. A "heaving" horse was to appear on the program, but unfortunately it expired. In that connection, Dr. West mentioned the case of southern horses brought into the midwest regions where they develop heaves, which is definitely a type of pulmonary emphysema.

Dr. Baldry commented that in many people with emphysema *per se,* unless they have had pulmonary chronic bronchitis, there does seem to be a constitutional factor involved.

Dr. Briggs then called on *Dr. Dean S. Fleming* who gave a report on a tuberculosis survey now being conducted among Mexican migratory workers in the Hollandale area. The survey is being made with the cooperation of the Christmas Seal organization and the Department of Employment and Security. Tests were given to 469 migrants and eighty-nine local people. The Mexicans were 39 per cent positive, and the local people 23.5 per cent positive.

Dr. Fleming stated that in general the children show negative findings. Beginning with the fifteen to nineteen year age group of migrants, 65 per cent were reactors. In early adulthood, almost 80 to 90 per cent reacted positively. The positive reactors have been x-rayed, but the results are not yet known. The Health Department hopes to obtain from this survey some age distribution of positive reactors. It may be much simpler, Dr. Fleming added, to x-ray all adult migrants.

LONGEVITY—BLOOD PRESSURE

Both life insurance companies and doctors will have to change their "sights" on blood pressure as a result of the largest statistical investigation ever made of the effects on longevity of increased blood pressure. This investigation covered the mortality experience over the years 1935-54. Its findings, just published under the title, "1959 Build and Blood Pressure Study," were made the first subject of discussion at the annual meeting of the Society of Actuaries held in New York City early in November, 1959.

Speaking of the findings on blood pressure, Dr. John J. Hutchinson of the New York Life Insurance Company, said, "Although this was not a clinical study, its implications should be of value to physicians. The consistent pattern of increased mortality from heart and circulatory diseases associated with slight increases in blood pressure emphasizes that clinicians cannot ignore the significance of small elevations in blood pressure. It is not reasonable to regard such variations as being within normal limits."

The actuaries agreed that even small elevations in blood pressure are associated with distinctly higher mortality and that this was the most notable finding of the four-year study. Most life insurance companies will have to reexamine their blood pressure ratings, they said, since the extra mortality found among persons with slight elevations in blood pressure may require the charging of an extra premium as a matter of fairness to other policyholders. The study, which covers nearly 4,000,000 persons, suggests that the incidence of elevated blood pressure is much higher than has been generally supposed.

The same comprehensive investigation revealed that persons with elevated blood pressure who were also overweight were subject to still higher mortality. This was likewise true of persons with elevated blood pressure and albuminuria.

On the other hand, the actuaries reported that during the past 60 years, there has been relatively little change in the excess mortality associated with overweight alone, except that tall overweights appear in recent decades to have become better risks. Accordingly, no major changes in life insurance ratings for overweights are anticipated. However, the ratings for underweight are expected to be lowered, because the mortality among underweights has improved considerably as compared with a generation ago when tuberculosis and pneumonia were the principal causes of death among such persons.

Moderate and marked overweight continues nevertheless to result in a serious impairment of longevity. Men weighing 35 pounds over average are subject to at least 25 per cent extra mortality, while men weighing as much as 50 pounds over average may experience up to 75 per cent higher mortality. The lowest mortality at ages over thirty is found among those 15 to 20 pounds below average weight which may, therefore, be considered as the best weight.

It is noteworthy, according to Mr. Lew, that nearly half of all men and women over thirty are 20 per cent or more above their best weights, although only about 6 per cent of all men and 11 per cent of all women weigh 20 per cent or more in excess of average.

Persons moderately or markedly overweight who reduced to about average weight were found to experience normal mortality for about ten years following reduction.

INSTITUTE OF LIFE INSURANCE

Communications

PRINCIPLES OF ETHICAL DRUG PROMOTION

We, members of the Pharmaceutical Manufacturers Association, recognizing our responsibilities and obligations to promote the public welfare and to maintain honorable, fair, and friendly relations with the medical profession, with associated sciences, and with the public, do pledge ourselves to the following statement of principles:

1. Prompt, complete, conservative and accurate information concerning therapeutic agents shall be made available to the medical profession.

2. Any statement involved in product promotional communications must be supported by adequate and acceptable scientific evidence. Claims must not be stronger than such evidence warrants. Every effort must be made to avoid ambiguity and implied endorsements. Whenever market, statistical or background information or references to unpublished literature or observations are used in promotional literature, the source must be available to the physician upon request.

3. Quotations from the medical literature or from the personal communications of clinical investigators in promotional communications must not change or distort the true meaning of the author.

4. If it is necessary to include comparisons of drugs in promotional communications, such comparisons must be used only when they are constructive to the physician and made on a sound professional and factual basis. Trademarks are private property that can be used legally only by or with the consent of owners of trademarks.

5. The release to the lay public of information on the clinical use of a new drug or of a new use of an established drug prior to adequate clinical acceptance and presentation to the medical profession is not in the best interests of the medical profession or the layman.

6. All medical claims and assertions contained in promotional communications should have medical review prior to their release.

7. Any violation of these principles brought to the attention of the President of the Pharmaceutical Manufacturers Association shall be referred by him to the Board of Directors.

(Passed by the Pharmaceutical Manufacturers Association Board of Directors, May 24, 1958)

HOW MANY MORE MEDICAL SCHOOLS?

No one can predict exactly the number of physicians needed in the future or the number of graduates needed to maintain a constant ratio between the two. The Bayne-Jones report recommended at least 8,700 medical graduates by 1970. The Surgeon General's Consultant Group on Medical Education recently recommended 10,400 M.D. graduates by 1975.

The following discussion is not based on either of the above estimates but rather upon a simple linear projection derived from past experience. These estimates of the future physician requirements correlate the expected population growth with a physician-population ratio of 132 physicians per 100,000 population which has prevailed over the last several years. Physician requirements computed on this basis and using the Census Bureau's Series II population estimates are shown in the first table.

Since 1930 the annual number of medical school graduates has averaged approximately 30 per 1,000 licensed physicians. The number of graduates projected in an estimate for succeeding years based on this rate is as follows:

Population Estimates	Physicians Needed (M.D.)	Graduates Needed (M.D.)
1960—180,126,000	237,766	7,133
1965—195,747,000	258,386	7,751
1970—213,810,000	282,229	8,467
1975—235,246,000	310,523	9,315
1980—259,981,000	343,175	10,295

ASSOCIATION OF AMERICAN MEDICAL COLLEGES

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

DISMISSAL OF ANTITRUST CHARGES

Of course, all of us at Lilly are pleased by the Court's decision that the poliomyelitis vaccine antitrust suit was so completely without basis that it was not even worthy of jury consideration. When the suit was first brought, we labeled it "complete nonsense," and we never had any doubt as to what the result would be.

We cannot help being deeply concerned that reputable business firms can be subjected to this kind of baseless attack. The harm done in terms of damage to public reputation by the mere bringing of the suit is incalculable. The waste of company executives' time and the expense of litigating such insupportable charges are deplorable.

Indianapolis, Indiana
December 1, 1959

EUGENE N. BEESLEY, *President*
Eli Lilly and Company

NOTE: In the United States District Court in Trenton, New Jersey, the Justice Department had charged that the five defendant manufacturers had conspired to fix prices of the vaccine. Judge Phillip Forman agreed with the defense attorneys that the Government had not proved its case and dismissed the suit without sending it to the jury.

Keogh-Simpson hearings end, 1459
Keogh-Simpson passes house, 610
Larson, Doctor, addresses Group Health Association of America conference, 1461
MD offers Forand "prescription," 1459
Major closed panel health care plans merged, 1111
Married women physicians stay with medicine, 279
Medical and voluntary health insurance plans for senior citizens accelerated, 757
Medical cost rising while price index holds firm, 60
Medical testimony plays major role in "pill bill" suit, 1642
Medicare benefits exceed $185 million mark, 1287
Medicine and third parties, 611
Minnesota governor urges greater medical care for the aged, 58
Minnesota labor views AMA medical care report, 449
Minnesota Board of Medical Examiners has busy year in 1958, 1285
Minnesota State Medical Association Foundation is formed, The, 451
More social security means a bigger staff, 138
New definition of disability hearing asked, 1459
New insurance claim forms simplified, 60
Now it's prescription insurance, 1642
People want to choose own doctor, survey shows, 58
Physicians are targets for income tax checks, 278
Physician's entertainment expense deductions defined, 278
Physicians warned to stop abusing insurance, 60
Problems of aged and aging aired in senate speech, 1820
Recent medical legislation trends reviewed, 758
Rural physician survey made in Pennsylvania, 140
Senator Humphrey is also health bill minded, 450
Senator Morse attacks organized medicine, 1460
State of medicine under socialization in England, 138
These figures speak for themselves, 278
U.S.-Group Health conduct prepaid mental care experiment, 758
Unionization of hospital employes in Minnesota may set national pattern, 607
Who needs a Forand bill? 278

Medical-Legal Opinions

Granger v. Adson et al, No. 29476 (basic trial case pertaining to the Medical Practice Act), 1825

Meetings and Announcements

1959 rural medical scholarship winner named, 627
AMA annual meeting will feature 450 physician speakers, 626
American Association on Mental Deficiency plans Minneapolis meeting, 1480
American College of Surgeons, Meetings of the, 1301
American Orthopsychiatric Association, 1851
American Urological Association award, 808
Arthritis and Rheumatism Foundation awards, 806
Asia-Pacific Academy of Ophthalmology, 1658
Automobile trauma symposium planned, 1484
Awards for obstetric papers, 808
Blue Earth Valley Medical Society, (Jan.) A-50
Clinics for crippled children, 1480
Continuation courses, (Jan.) A-52, 286, 470, 1122, 1846
Course for care of chronically ill patient, 1482
Course in conduct of labor and delivery, 806
Course in industrial eye problems, (Jan.) A-52
Doctors' nurses organize, 1124
Exhibition of art works by American physicians, 628
Eyes in industry course announced, 1652
Fellowships for study of arthritis and related diseases, 1656
"Fight alcoholism day" observed, (Jan.) A-52
Hearing Society announces award competition opening, (Feb.) A-52
International Academy of Proctology award contest, 1851
Mayo Clinic annual staff meeting, (Jan.) A-48
Mayo Clinic reviews dates set, (Jan.), A-48 (Feb.), A-52
Medical alumni dinner planned, 1482
Medical social work scholarships, 286
Minnesota Academy of Occupational Medicine and Surgery, 1652
Minnesota Obstetrical and Gynecological Society, (Jan.), A-52
Monograph prizes offered by the American Academy of Arts and Sciences, 627, 1850
"NAME" organized, (Jan.), A-54
National Society for Crippled Children and adults offers grants, 1126
Neurophysiology research funds available, 627
New publication, The Journal of Nuclear Medicine, 1656
New York University Postgraduate Medical School, 284, 1302, 1484
Northern Minnesota Medical Association, 1300, 1482
Openings in graduate courses, 628
Ophthalmology courses offered, 1850
Pediatric short courses, 470
Postgraduate courses in diseases of the chest, 1301
Prize essay contest for medical students announced, 1656
Program arrangement available to county societies, 284
Radiation protection motion picture for physicians, 470
Red River Valley Medical Society, (Jan.) A-50
Rehabilitation workshop planned, 1482
Research in prevention of blindness, (Feb.) A-52
Results of County Medical Society elections: Blue Earth, Clay-Becker, Park Region, Red River Valley, St. Louis and Winona, (Feb.) A-54
Southern Minnesota Medical Association, 1301
Submission of bills for services rendered to army military personnel by civilian hospitals and physicians, (Jan.), A-48
Symposium on diseases of the liver and bile ducts, 628
TV show about human senses, 1658
Two fellowships offered in audiology and speech, 274
University of Nebraska postgraduate course, 1124
Venereal diseases symposium scheduled, (Feb.) A-52
World Medical Association tour, 284

Minnesota State Board of Medical Examiners

Drug addict posing as physician given seven-year prison term, 136
Hennepin County man given one-year probationary term for representing himself as doctor, 1822
Minneapolis machinist sentenced to serve three years on abortion charge, 61
Physician's license suspended for five years for narcotic violations, 451
Roseau County healer sentenced for basic science violation, 1670
Student posing as doctor given ninety-day term in St. Paul workhouse, 605
Unlicensed chiropractor sentenced at Chaska for unlawful sale of drugs, 274

Minnesota State Medical Association

Guest speakers, 613
Highlights of actions taken by the House of Delegates, 106th annual meeting, 953
Preliminary program—106th annual meeting, 443
Roster, 761
Scientific exhibits, 616
Sports events and outings, 617

when you see signs of anxiety-tension specify

Dartal®

dihydrochloride

brand of thiopropazate dihydrochloride

for rapid relief of anxiety manifestations

You will find Dartal outstandingly beneficial in management of the anxiety-tension states so frequent in hypertensive or menopausal patients. And Dartal is particularly useful in the treatment of anxiety associated with cardiovascular or gastrointestinal disease, or the tension experienced by the obese patient on restricted diet. You can expect consistent results with Dartal in general office practice.

with low dosage: Only one 2, 5 or 10 mg. tablet t.i.d. *with relative safety:* Evidence indicates Dartal is not icterogenic.

Clinical reports on Dartal: 1. Edisen, C. B., and Samuels, A. S.: A.M.A. Arch. Neurol. & Psychiat. *80*:481 (Oct.) 1958. 2. Ferrand, P. T.: Minnesota Med. *41*:853 (Dec.) 1958. 3. Mathews, F. P.: Am. J. Psychiat. *114*:1034 (May) 1958.

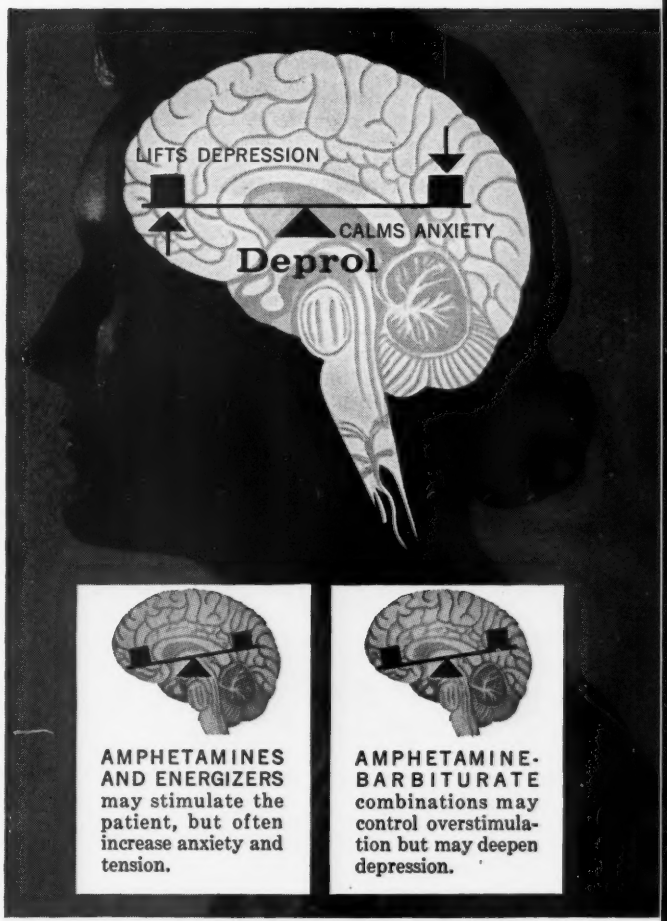
Lifts depression..

An emotionally balanced patient
Thanks to your treatment and the help of Deprol, her depression is relieved and her anxiety and tension calmed. She eats well, sleeps well, and can return to her normal activities.

..s it calms anxiety!

)eprol helps balance the mood y lifting depression as it alms related anxiety

No "seesaw" effect of amphetamine-barbiturates and energizers



While amphetamines and energizers may stimulate the patient—*they often aggravate anxiety and tension.* And although amphetamine-barbiturate combinations may counteract excessive stimulation—*they often deepen depression.*

In contrast to such "seesaw" effects, Deprol lifts depression as it calms anxiety—both at the same time.

Safer choice of medication than untested drugs

Deprol does not produce hypotension, liver damage, psychotic reactions or changes in sexual function.

Here's the ultimate of

RUBBER-REINFORCED BANDAGES!

HIGHEST CONTENT
OF HEAT RESISTANT RUBBER
AND QUALITY COTTON THREADS

The ultimate of elastic bandages based on all comparative features. The combination of quality cottons and "heat resistant rubber" threads in a perfect balance assures a finer more rugged product. Consider the thread count, rubber content,* weight per square yard, length of bandage and all contributing factors.

P&H RUBBER REINFORCED BANDAGES will be found to be the best in every respect, where comparative testing is done. After considering every quality feature then consider economy. You'll find you are way out front —in every respect.

Contains twice as many rubber threads as most other brands.

MONOGRAPH PRIZES OFFERED

The American Academy of Arts and Sciences has announced three $1,000 prizes to be awarded annually to the authors of unpublished monographs; one each in the fields of the Humanities, Social Sciences and Physical and Biological Sciences.

The final date in 1960 for receipt of manuscripts by the Committee on awards is October 1. Announcement of the awards will be made in December, 1960.

Full details concerning these prizes may be secured on request by sending a stamped self-addressed envelope to the Committee on Monograph Prizes, American Academy of Arts and Sciences, 280 Newton Street, Brookline Station, Boston 46, Massachusetts.

OPHTHALMOLOGY COURSES OFFERED

The New York University Postgraduate Medical School offers the following courses in Ophthalmology starting in February, 1960:

Ophthalmic Plastic Surgery (for specialists)—A part-time course, 2 to 5 p.m., February 29 through March 4, 1960—Covers the essentials of ophthalmic plastic surgery for the practicing ophthalmologist. Special emphasis is laid on the more common fundamental procedures peculiar to lid surgery. Under the direction of Dr. Sidney A. Fox.

Motor Anomalies of The Eye (for specialists)—A full-time course given in two parts: Part I, March 7 through 12, 1960. The course is made as practical as possible, and the relation of the muscle balance to refraction is always considered in the prescribing of glasses. Part II, March 14 through 18. The question of treatment, both operative and non-operative, and the use and limitations of each are considered. Under the direction of Dr. Harold W. Brown.

Ocular Expressions of Systemic Disease—A part-time course, 2 to 5 p.m., March 21 through 25, 1960. Covers clinical and pathological changes associated with diabetes, hypertension, nephritis, thyroid dysfunction, blood dyscrasias, and optic nerve disease. Some associated eye and skin evidences of systemic diseases are discussed. Under the direction of Dr. Isadore Givner.

Surgery of the Eye (for specialists)—A full-time course, March 28 through April 2, 1960. Consists of lectures on cataract surgery, glaucoma surgery, ocular muscle surgery, ptosis surgery, surgical treatment of retinal detachment, corneal transplantation, and plastic surgery of the eye. Practical work on technique of eye operations on the cadaver. Under the direction of Dr. Rudolph Aebli.

Ophthalmoscopy—A part-time course, 9 a.m. to 12 noon, April 25 through 29, 1960. A study of the normal fundus, congenital anomalies, diseases of the vitreous, retina, choroid, optic nerve head, and traumatic fundus changes. Under the direction of Dr. George N. Wise.

Histopathology—A part-time course, 1 to 4 p.m., April 25 through 29, 1960. Consists of lectures, demonstrations, and microscopic study of exemplary material covering the following subjects: Intraocular inflammation, pyogenic, granulomatous, and nongranulomatous; glaucoma and hypotension; trauma; intraocular tumors; fibroblastic states; vascular-metabolic states. Under the direction of Dr. A. Marvin Gillman.

For additional information, write to: Office of the Associate Dean, New York University Postgraduate Medical School, 550 First Avenue, New York 16, New York.

INTERNATIONAL ACADEMY OF PROCTOLOGY AWARD CONTEST

The International Academy of Proctology announces its Annual Cash Prize and Certificate of Merit Award Contest for 1959-1960. The best unpublished contribution on proctology or allied subjects will be awarded $100.00 and a Certificate of Merit. The winning contribution will be selected by a board of impartial judges, and all decisions are final.

The formal award of the first prize, and presentation of other certificates, will be made at the annual convention dinner dance of the International Academy of Proctology, April 27, 1960, at the Americana Hotel, Miami Beach, Florida.

The International Academy of Proctology reserves the exclusive right to publish all contributions in its official publication, *The American Journal of Proctology*. All entries are limited to 5,000 words, must be typewritten in English, and submitted in five copies. All entries must be received no later than the first day of February, 1960. Entries should be addressed to: Alfred J. Cantor, M.D., International Academy of Proctology, 147-41 Sanford Avenue, Flushing 55, New York.

AMERICAN ORTHOPSYCHIATRIC ASSOCIATION

Specialists in the behavioral sciences from all parts of the United States and Canada will focus on mental health problems of the community and society at the 37th annual meeting of the American Orthopsychiatric Association on February 25-27, 1960, at the Sherman Hotel, Chicago.

The program will include joint sessions with the American Public Health Association, the World Federation of Mental Health, the American Group Psychotherapy Association, the Society for Projective Techniques, the American College Health Association and the American Association of Psychiatric Clinics for Children.

Topics to be covered in more than seventy scientific papers include: animal research, genetics of mental disease, management of brain-damaged adolescents, total care program for psychiatric patients, special school program for emotionally disturbed children, learning problems, desegregation process and delinquency.

Further information is available from Dr. Marion F. Langer, Executive Secretary, American Orthopsychiatric Association, 1790 Broadway, New York 19, New York.

LEVOPHED MAINTAINS BLOOD PRESSURE IN BACTEREMIC SHOCK

Levophed (norepinephrine) by intravenous infusion was the only drug capable of maintaining blood pressure in an obstetrics patient with bacterial shock unrelated to blood loss, according to Dr. Harry Oxorn of McGill University.

Writing in the *American Journal of Obstetrics and Gynecology* (78:567, 1959), he reports on measures used in the management of a case of premature delivery at seven months. Bacterial shock developed seven hours after delivery of a dead fetus. The patient had experienced spontaneous rupture of the membranes two days previously.

Treatment of the bacterial shock by infusion of a plasma expander was of little help. Levophed (Winthrop) raised blood pressure, which had been unobtainable, to 120/70 and maintained it at 100 mm. for the next five days, Dr. Oxorn states. Blood pressure was extremely labile, he notes, but responded immediately to an increase in the infusion rate of Levophed.

He cites similar cases reported by another research group, which also concluded that Levophed appeared to be the only agent able to restore and maintain blood pressure. In his own case report, he says that hydrocortisone and antibiotics were given and close attention paid to fluid balance.

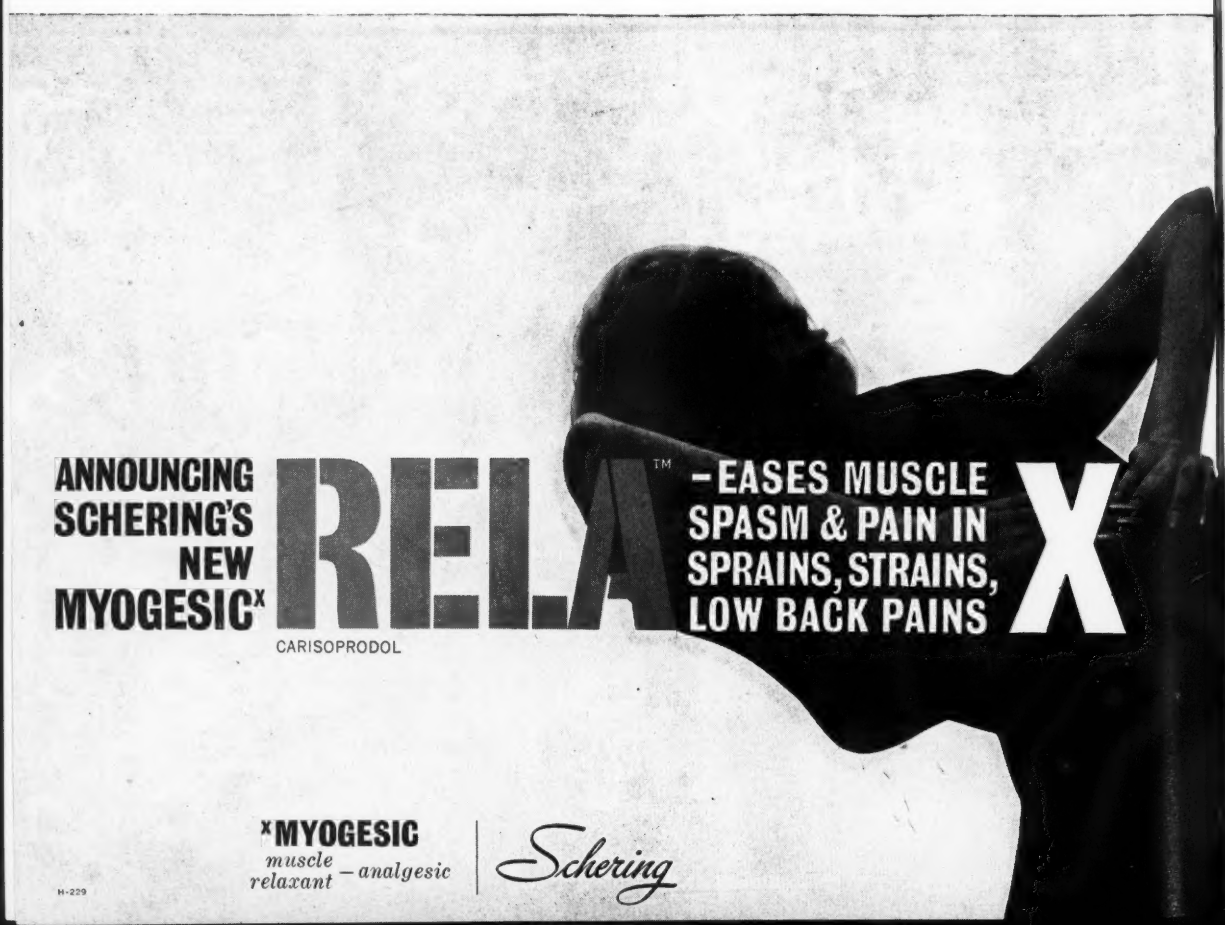
Woman's Auxiliary

ZUMBRO VALLEY ACTIVITIES

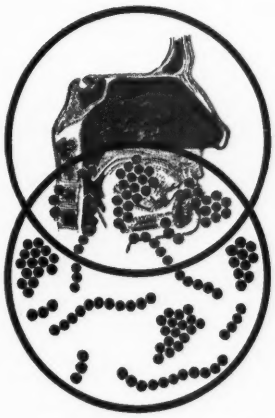
The Zumbro Valley Medical Auxiliary held its quarterly fall meeting on November 5, 1959, at the Ability Building Center, located at the Samaritan Nursing Home in Rochester, Minnesota. Mrs. M. F. Fellows of Duluth, state auxiliary president, was a special guest.

A panel discussion on the Ability Building Center and a tour of the workshop was held. Panelists were Mrs. G. M. Lowry, member of the board of directors of the ABC and one of the organizers of the project; David Griggs, managing director of ABC; Charles Timm, office supervisor; Kenneth Zubay, president of ABC; and Dr. D. J. Erickson of the Mayo Clinic.

The ABC was incorporated in 1956 and is an Easter seal affiliate. From three workers, the organization has grown to between forty-five and fifty employes, with a constant turnover as the disabled persons find permanent employment. Dr. Frank Krusen, of the Mayo Clinic, with Dr. D. J. Erickson, helped to establish the institution because of the need to place disabled persons in gainful work. Many of the employes at the center are now able to make their own living, rather than be on state aid.



The auxiliary currently is planning a Christmas party to be held at the Ability Building Center for the employes. Each month members of the auxiliary provide cookies for a special party which is held for the disabled workers who are employed at the center at that time.



The Zumbro Valley Medical Auxiliary officers and committee chairmen are as follows: Mrs. O. H. Beahrs, president; Mrs. J. E. Edwards, vice president; Mrs. D. G. Hanlon, treasurer; Mrs. John E. Verby, Secretary; Mrs. James K. Masson, press and publicity; Mrs. G. M. Martin and Mrs. D. J. Erickson, membership; Mrs. A. A. Frethem, American Medical Education Foundation; and Mrs. J. W. DuShane, legislation.

STEELE COUNTY AUXILIARY ENTERTAINS FUTURE NURSES

The Steele County Medical Auxiliary entertained high school sophomores who are interested in nursing on the afternoon of October 20 at Owatonna. Miss Melbostad, Owatonna school nurse, and Miss Pat Manley, Steele County public health nurse, spoke to the

(Continued on page 1868)

when upper respiratory congestion is complicated by bacterial invaders

TRISULFAMINIC provides logical therapy

- for the patient ill with congestion and infection of the upper respiratory tract, as in purulent rhinitis, sinusitis, tonsillitis and otitis media, when caused by sulfa-susceptible bacteria;
- because secondary invasion by such bacteria so frequently follows the common cold.[1]

the reasons for combining Triaminic with triple sulfas

Triaminic and triple sulfas are not only pharmacologically *compatible*, they are a therapeutically *logical* combination for upper respiratory infections: Triaminic for effective decongestant relief from rhinitis, rhinorrhea and sinusitis;[2] triple sulfas for well-established antibacterial action.

The advantages of Trisulfaminic in upper respiratory infections include: proved effectiveness; safety; economy; ease of administration; less likelihood of sensitivity reactions;[3] compatibility with antibiotics and other antibacterial therapy. Provided also as Suspension for additional convenience.

Trisulfaminic®

TRIAMINIC WITH TRIPLE SULFAS

Available as TABLETS and SUSPENSION

Each easy-to-swallow Trisulfaminic Tablet or 5 ml. teaspoonful of Suspension provides:

Triaminic® .....25 mg.
(phenylpropanolamine HCl 12.5 mg.
pheniramine maleate ..... 6.25 mg.
pyrilamine maleate ..... 6.25 mg.)
Trisulfapyrimidines, U.S.P. .....0.5 Gm.

Dosage:

Adults—2 to 4 tablets or tsp. initially, followed by 2 tablets or tsp. every 4 to 6 hours until the patient has been afebrile 3 days. *Children 8 to 12* — 2 tablets or tsp. initially, followed by 1 tablet or tsp. every 6 hours. *Children under 8*—dosage according to weight.

The palatability, convenience and effectiveness of the Suspension make it especially suitable for children and for those older patients who prefer liquid medication.

SENATOR HOLAND ADDRESSES MOWER COUNTY AUXILIARY

Senator P. J. Holand addressed the Mower County Medical Auxiliary on October 26 at the home of Mrs. L. G. Flanagan.

Members also discussed an essay contest for high school students and a film was shown.

DISTRICT FOUR MEETING HELD AT MANKATO

The District Four auxiliary meeting was held recently in Mankato at the home of Mrs. Alton Lindblom, Langness Heights. Mrs. Lindblom is regional advisor of the auxiliary. Assisting as hostesses were Mrs. A. M. Scheidel and Mrs. John C. Wohlrabe.

Mrs. M. F. Fellows of Duluth, state auxiliary president, and Mrs. W. P. Gardner of St. Paul, president-elect, were special guests. Mrs. Fellows brought out five points for the auxiliary program in her talk—membership, subscribing 100 per cent to the national bulletin; American Medical Foundation where money is needed for student aid and scholarships; equipment and salaries for added teachers; and legislative matters, knowing every bill concerning medicine and how it affects members; and Allied Careers, encouraging young people to take up medical careers.

Mrs. Gardner encouraged all doctors' wives to join the auxiliary and to watch for the daily radio program over KYSM to be called "Doctor, Tell Me."

District Four consists of Blue Earth, Brown, McLeod, Nicollet-Le Sueur, Scott-Carver and Waseca counties. Each was represented by officers or members of their respective counties.

WRIGHT COUNTY MEDICAL AUXILIARY

The Wright County Medical Auxiliary held its November 3 meeting in Buffalo. After dinner, the business meeting was held at the home of Mrs. Robert Sandeen.

Auxiliary officers for the year are as follows: Mrs. R. D. Thielen of St. Michael, president; Mrs. W. E. Hall, Maple Lake, vice president; Mrs. G. Purves, Buffalo, secretary-treasurer; Mrs. T. J. Catlin, Buffalo, historian; Mrs. Purves, Buffalo, Bulletin chairman; Mrs. W. P. Anderson, Buffalo, cancer; Mrs. W. E. Hart, Monticello, civilian defense; Mrs. W. T. Greenfield, Cokato, medical and surgical relief; Mrs. F. E. Ellison,

DISTRICT ONE MEDICAL AUXILIARY SESSION

A regional meeting of the Woman's Auxiliary was held at the Oaks in Winona on October 28. County medical auxiliaries in District One represented at the meeting included Rice, Steele, Zumbro Valley, Wabasha, Goodhue, Mower, and Winona.

A one o'clock luncheon preceded the program. State committee chairmen were speakers. Mrs. W. P. Gjerde of Lake City spoke on mental health; Mrs. Warren Wilson, Northfield, on medical and surgical relief; and Mrs. John W. Gridley, Arlington, on the American Medical Education Foundation.

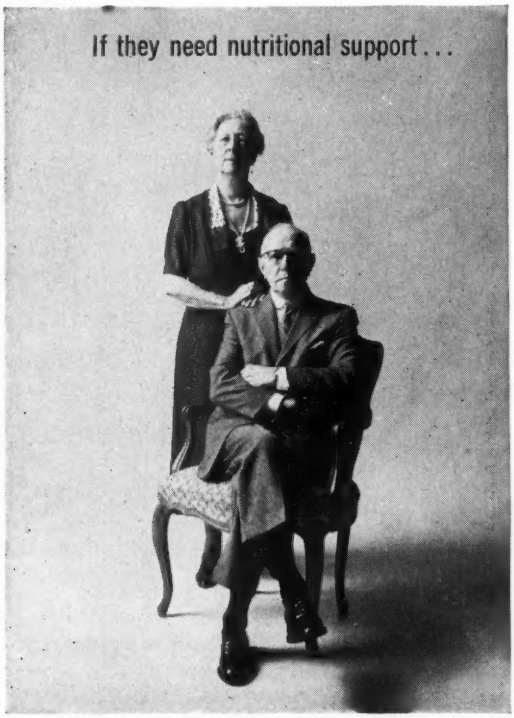
RAMSEY COUNTY AUXILIARY

Board members of the Ramsey County Medical Auxiliary met on November 10 in the Medical Arts Library, St. Paul. Mrs. Hanns Schwyzer called the meeting to order, and representatives of Community Service Committees gave reports on meetings they had attended.

Mrs. David Norman gave a detailed account of the Civil Defense meeting she and Mrs. Neil recently attended in Minneapolis. Literature and questionnaires will be distributed to the auxiliary. Members are requested to answer the questions and return them to the organization.

Mrs. Charles Froats, American Red Cross representative, told of the need for Grey Ladies and for helpers for the blood bank—the main project of the Auxiliary for the year.

Edna Imm, portrait painter, presented a demonstration of her work at the November luncheon and meeting held in the University Club.



MEDICAL AUXILIARY TEA IN GRAND RAPIDS

Members of the Range medical auxiliary from Duluth, International Falls, and the Range towns attended the organization's annual fall membership tea on Thursday, October 15, in Grand Rapids at the home of Dr. and Mrs. A. V. Grinley.

Auxiliary president is Mrs. R. T. Kelly of Grand Rapids. Other officers are Mrs. Bernard Flynn of Hibbing, vice president; Mrs. Vernon Erickson of Grand Rapids, secretary; and Mrs. Donald Nollett of Hibbing, treasurer.

Mrs. M. F. Fellows of Duluth, state president, and Mrs. Roy Pedersen of Duluth, para-medical career state chairman, were present for the afternoon.

Tea arrangements were under the direction of Mrs.

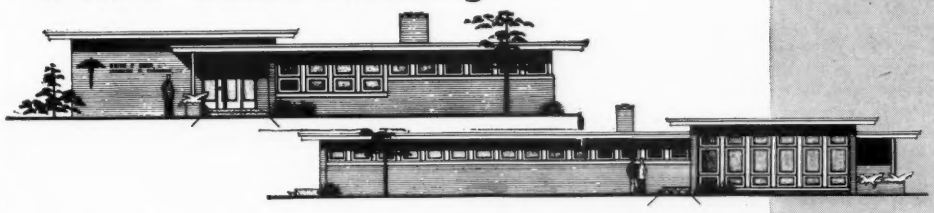
Grinley, chairman, and committee members, Mrs. R. W. Brockway and Mrs. Kelly of Grand Rapids, and Mrs. Kelly Rowles of Coleraine. Other Grand Rapids physicians' wives were hostesses.

Mrs. Andrew Sinamark of Hibbing is the auxiliary's membership chairman. Other members of her committee are Mrs. A. N. Antonow of Virginia and Mrs. L. E. Karges of Grand Rapids.

SOUTHWESTERN MEDICAL AUXILIARY

The regular meeting of the Southwestern Minnesota Medical Auxiliary was held October 26 at the home of Dr. and Mrs. Robert Sawtell of Worthington, following a dinner for members of the Medical Society and their wives at a local steak house. Special guests were Mrs. M. F. Fellows of Duluth, state president, and Mrs. W. P. Gardner of St. Paul, president-elect. Mrs. Fellows spoke to the group, giving a brief résumé of the School of Instruction and presenting the current goals of the auxiliary. Mrs. R. J. Kotval of Pipestone, vice-president, presided.



REGION THREE MEETING HELD

A Region Three meeting was held in Marshall on Tuesday, November 3, 1959, at the Marshall Cafe. Mrs. M. I. Hauge, Region Three Advisor, presided at the meeting. Representatives from three medical auxiliaries, Camp Release, Lyon-Lincoln, and Renville-Redwood, attended. Mrs. M. F. Fellows, State President, was the honored guest.

After a welcome by Mrs. R. T. Olson, President of Lyon-Lincoln Auxiliary, Mrs. M. F. Fellows gave a résumé of the fall school of instruction. Mrs. J. Strauchler, AAPS Essay Contest chairman, gave a brief talk on the essay contest and urged each auxiliary to sponsor the contest. Arrangements were made to have a spring meeting.

In Memoriam

FRANK H. CLAY

Dr. Frank H. Clay, retired, died at Winter Park, Florida, on November 6, 1959. He was seventy-five years of age at the time of his death.

Doctor Clay graduated from the University of Minnesota School of Medicine in 1909. He practiced in Winona and St. Charles and was a member of the Winona County Medical Society and the Minnesota State Medical Association.

He is survived by his wife, Alice, of Longwood, Florida; one daughter, Mrs. John Hanner, Longwood; two sons, Leland H. Clay, Beverly Hills, California, and Doctor Lyman B. Clay, Minneapolis; and one brother, Doctor R. L. Clay, Lewiston, Minnesota.

ROBERT K. GRAU

Dr. Robert K. Grau, of St. Paul, died October 31, 1959, at the age of fifty years. The deceased was a member of the staff at St. Luke's, Midway, Children's, and Bethesda Hospitals in St. Paul.

He was a member of the Ramsey County Medical Society, the Minnesota State Medical Association, and the American Medical Association. He was also a Mason and Shriner. Other memberships held by Doctor Grau included the following: American Academy of General Practice; American Association of Railway Surgeons; Midland Hills Golf Club; St. Paul Athletic Club; Midway Civic Club. He was a member of the Merriam Park Presbyterian Church.

The deceased was born in Manning, Iowa, and received his preliminary education in the Dennison, Iowa, public schools. He attended the University of Iowa, Iowa City, and obtained his medical degree from the University of Iowa.

He is survived by his widow, Sadie, daughter, Barbara Lynn, both of Falcon Heights; his mother, Mrs. Emma Grau of Dennison, Iowa, and two brothers, Dr. A. H. Grau of Dennison, and Walter Grau of Walnut Creek, California.

BENEDIK MELBY

Dr. Benedik Melby, a Blooming Prairie physician for fifty-four years, died October 11, 1959. He was eighty-one years old at the time of his death. Doctor Melby was born in Whitehall, Wisconsin, and attended high school at Merrillan, Wisconsin. He graduated from the University of Minnesota Medical School and interned at Abbott Hospital in Minneapolis. He practiced medicine for one year at Hayfield, Minnesota, before coming to Blooming Prairie in 1905. The deceased was active in civic affairs during the majority of his life time. He was a member of the Blooming Prairie board of education from 1916 to 1955 and received the "Distinguished Service Award" from the Minnesota Education Association in 1950. He was also a member of the American Medical Association, Minnesota State

Medical Association, Steele County Medical Society, Masonic lodge, Eastern Star, Shrine organization, Commercial club and Blooming Prairie Lions club.

On June 17, 1953, the Blooming Prairie community held a Doctor Melby night in honor of the Blooming Prairie physician. He was also awarded a "fifty-year pin" at the Minnesota State Medical Association meeting in 1953 at St. Paul.

Survivors include his widow, Julia; one daughter, Lois Melby of Anoka, Minnesota, and three sisters, Miss Elizabeth Melby of New Haven, Connecticut, Mrs. Ben Isbill of Auburn, Washington, and Mrs. Nellie Anderson of Auburn, Washington.

CHESTER J. OLSON

Dr. Chester J. Olson, physician and surgeon in the Belle Plaine community for thirty-four years, died October 19, 1959, following a heart attack. He was sixty-four years old at the time of his death.

The deceased was a native of Dassel, Minnesota. He was a graduate of the University of Minnesota Medical School and served his internship in a White Springs, New York, Hospital. He was also a registered pharmacist.

Dr. Olson began his practice in Belle Plaine in 1925 as an associate of Dr. F. J. von Bohland. The following year, he acquired the von Bohland practice. He was a member of the Scott-Carver County Medical Society, Minnesota State Medical Association, and the American Medical Association.

He is survived by his wife Alyce, his sister, Mrs. Elmer Dahlin, and an uncle, Dr. O. A. Olson.

KARL A. WALFRED

Dr. Karl A. Walfred, of St. Cloud, died October 22, 1959, at the age of sixty-nine years. For the past four years, Doctor Walfred had served as Stearns County coroner.

The deceased received his early education in Isanti County and was graduated from Bethel Academy in 1911. In 1917, he received his Bachelor of Science degree from the University of Minnesota. His schooling was interrupted for a period during World War I, when he served in the Army. Upon his return he continued his studies at the University, receiving his Doctor of Medicine degree in 1922.

Doctor Walfred practiced in Raymond until 1924, when he moved to Cold Spring, where he was in practice for six years. In 1934, he moved to St. Cloud and had been in practice there since.

Doctor Walfred was a member of the Stearns-Benton County Medical Society, the Minnesota State Medical Association, and the American Medical Association. He was also a member of the General Practitioners of Minnesota, a past president of the staff at St. Cloud hospital and was listed in Who's Who of Physicians and Surgeons of the World.

Surviving are a sister Mrs. Josephine Hatfield, San Francisco; and brothers Paul Anderson, Minneapolis and Dr. F. E. Anderson, Underwood, North Dakota.

The Physician's Diary

Tribute to **Dr. J. Arthur Myers** of the University of Minnesota, international authority on tuberculosis, was paid by **Dr. Willard E. Peterson** of Willmar, at the regional conference on tuberculosis in Willmar on October 28. Dr. Myers, principal speaker at the dinner meeting at the Elks Club, stressed the value of using Minnesota's strong tuberculosis control program to detect active TB, especially in view of the several recent outbreaks of the disease in different parts of the state. Dr. Peterson, president of the Kandiyohi County Tuberculosis and Health Association, presided at the four-county meeting. At the meeting were about 50 volunteer Christmas Seal workers, public health nurses, and medical and civic leaders from Kandiyohi, Meeker, Redwood and Renville counties.

* * *

Dr. A. B. Rosenfield, director of the division of special services of the Minnesota Department of Health, has been elected president of the Minnesota Public Health Conference for 1960. Other officers include **Dr. Robert K. Anderson,** professor of veterinary bacteriology and public health, University of Minnesota, first vice president, and **Dr. Stewart C. Thomson,** professor and associate director of the School of Public Health, University of Minnesota, treasurer.

* * *

Dr. Vernon G. Kuhlmann has joined **Dr. James Reinhardt** in the practice of medicine in Alexandria. A specialist in surgery, Doctor Kuhlmann was released from the U. S. Navy in July after completing his required years of service.

* * *

Dr. John F. Briggs, St. Paul internal medicine specialist, addressed the St. Paul and Minneapolis District Dental Societies at their annual combined meeting on November 10. His speech was on "The Professional Man's Dilemma."

* * *

Four members of the faculty of the Mayo Foundation have been elected to the University Senate of the University of Minnesota. They are: **Drs. O. T. Clagett, K. B. Corbin, Victor Johnson** and **R. D. Miller,** all elected by faculty ballot. Dr. Johnson also served as a Senate member last year.

* * *

Dr. Donald D. Metz, who has conducted a medical practice at the Buffalo Lake Community Clinic the past five years, has accepted a position at the Robbinsdale Clinic. He began his work in Robbinsdale on November 1, where he is now associated with **Dr. Roger Lienke** and **Dr. Frank Rice** at the Robbinsdale Clinic.

* * *

Dr. J. E. Douglass, medical director of the Mineral Springs sanatorium, Cannon Falls, was the principal speaker at the eight-county conference on tuberculosis at the sanatorium on October 20. Attending were volunteer health workers, physicians and civic leaders interested in public health problems of Goodhue, Dakota, Freeborn, Mower, Olmsted, Rice, Steele and Washington counties.

* * *

The Hennepin County Tuberculosis Association was represented by **Dr. Charles E. Merkert,** member of the board, at the recent Mississippi Valley Conference of Tuberculosis held in Springfield, Illinois.

* * *

Dr. Walter E. Hinz, associated with the Lakeland Medical Center in Willmar, attended a graduate refresher course in obstetrics and gynecology, conducted by Northwestern University's medical school.

* * *

A course for public health nurses on emotional problems of the adolescent was held November 9-10 at the University of Minnesota's Center for Continuation Study. The faculty included: **Dr. Gove Hambidge, Jr.,** Minneapolis psychiatrist, and **Dr. Carl Schwartz,** psychiatrist with the Mower County Mental Health Unit.

* * *

Dr. Robert L. Stein is now associated with **Dr. J. W. Bratholdt** and **Dr. D. R. Philp** in their medical practice in Watertown.

* * *

Dr. Harold Hermann, Minneapolis pediatrician, was the speaker at a recent meeting of the Watertown PTA. The theme of the meeting was "Adjustments to Life," and Dr. Hermann's subject was "The Parents' Responsibility in Sex Education to Their Children."

* * *

The gap between hospitals and the Duluth Rehabilitation center must be bridged, the St. Louis County Medical Society was told recently by **Dr. Frederic J. Kottke,** head of the University of Minnesota department of physical medicine and rehabilitation. Dr. Kottke declared that "Too many patients are lost between the hospital and center." These are patients who are in no condition to go to the center for care when released from the hospital, he explained. He advocated use of a psychiatrist who specializes in rehabilitation to chart a "complete rehabilitation program" for patients and creation of facilities into which bedridden patients needing rehabilitation could be transferred from the hospital.

* * *

The University of Minnesota regents have elected **Dr. Charles W. Mayo,** Rochester, vice chairman and second vice president of the board. Dr. Mayo succeeds Regent George W. Lawson, St. Paul, who died in September.

Annual Clinical Conference

Recently elected officers of the Minneapolis Obstetrical and Gynecological Society are: Doctors **Maxwell M. Barr**, president; **George W. Janda, Jr.**, vice president; and **Richard R. Fliehr**, secretary-treasurer. The Society plans four meetings during the coming year, the first meeting being held at the Minneapolis Athletic Club on December 9. **Dr. Joseph Pratt** of the Mayo Clinic will be the featured speaker, presenting "The Newer Aspects of Gynecological Surgery."

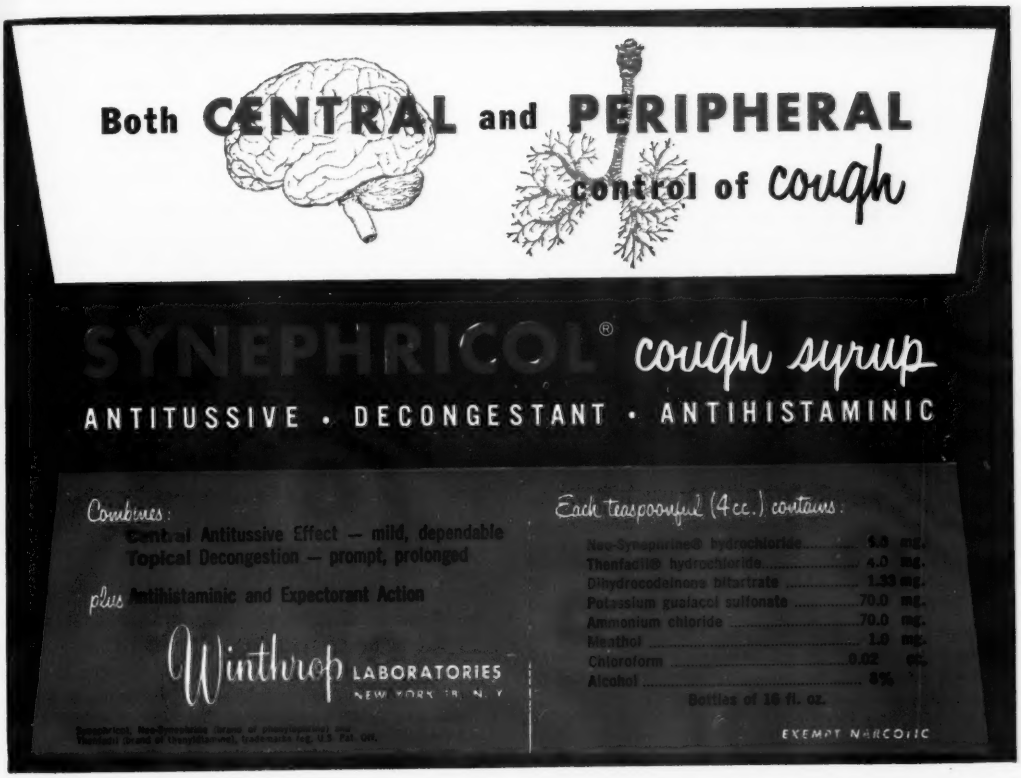
* * *

Dr. William H. ReMine, head of a section of surgery at the Mayo Clinic, and assistant professor of surgery in the Mayo Foundation, Graduate School, University of Minnesota, has been judged winner of an award for his surgical motion picture, "The Embryologic Development and Management of Branchial Cleft Cysts and Sinuses" by the American College of Surgeons. The film was shown at the clinical congress of the American College of Surgeons in Atlantic City on September 28 to October 2, and the award will be presented to Dr. ReMine at the 1960 clinical congress of the organization.

* * *

At the regular meeting of the Minnesota Society of Neurology and Psychiatry held in St. Paul on November 10, the scientific program included the following presentations: "The Anatomy of Savor" by **Dr. Edward C. Clark**, Rochester, and "Differential Treatment and Prognosis in Schizophrenia" by **Dr. Werner Simon**, Minneapolis.

* * *



The Minnesota Medical Foundation, on October 30, awarded a grant of $13,716 to the University of Minnesota Medical School's department of medicine to finance a two-year program of diabetes research. A research team directed by **Dr. Frederick C. Goetz** will use the funds to seek development of substitutes for insulin in treatment of diabetes. The funds were willed to the Foundation by the late Eva Rhodes Freeman of Minneapolis. The grant for research purposes is the first ever given by the Foundation, according to **Dr. Herman E. Drill** of Hopkins, president. Four new trustees were elected to four-year terms on the Foundation board. They are **Dr. Corrin H. Hodgson**, Rochester; **Dr. Milton M. Hurwitz**, St. Paul; **Dr. Anderson C. Hilding**, Duluth; and **Dr. John A. Anderson**, St. Paul, who was also named to a one-year term as secretary-treasurer. Also re-elected to a four-year term was **Dr. Bernard Halper**, Hibbing.

* * *

Dr. Khalil G. Wakim, a member of the Section of Physiology of the Mayo Clinic, and professor of physiology in the Mayo Foundation, Graduate School, University of Minnesota, has been elected unanimously to honorary membership in the North Central Section of the American Urological Association, Inc.

* * *

Dr. Edgar V. Allen, internist of the Mayo Clinic and professor of medicine in the Mayo Foundation, Graduate School, University of Minnesota, received the Gold Heart Award of the American Heart As-

sociation at the annual dinner of the organization at the Bellevue-Stratford Hotel in Philadelphia on October 25. The award, described as "the highest honor within the gift of the association," was conferred upon Dr. Allen by unanimous selection of the committee on awards and the board of directors of the organization, in recognition of his "outstanding contributions in advancing the objectives and program of the American Heart Association."

* * *

Two Minneapolis physicians have been appointed to the medical staff of Doctors Memorial Hospital, according to announcement by Clarence R. Chaney, vice president of the board of directors. They are **Dr. L. E. Christensen,** ophthalmologist, and **Dr. Fred Bedford,** general practitioner, who recently returned after practicing in Montrose, Colorado. There are now seventy-seven doctors on the hospital's staff.

* * *

Dr. **Sumner Cohen,** Oak Terrace, was the principal speaker at a meeting of the St. Louis County Medical Society at St. Luke's Hospital in Duluth recently. Doctor Cohen spoke on the "Responsibility in Present-Day Tuberculosis Treatment and Control." The paper was the Third Annual Arthur T. Laird Lecture sponsored by the Tuberculosis and Health Association of St. Louis County.

St. Paul physician, **Dr. William R. Heilig,** has been elected as a Fellow of the American Academy of Pediatrics. The announcement came from the Academy's international office at Evanston, Illinois.

* * *

A key speaker at the Michigan Rehabilitation Conference held recently at Traverse City, Michigan, was **Dr. Miland E. Knapp,** Minneapolis. Doctor Knapp spoke on "Research in Rehabilitation." He also participated on a panel discussion on poliomyelitis research.

* * *

Stearns County Board of Commissioners recently named **Dr. S. H. Koop,** St. Cloud, as County Coroner, to serve the remainder of the term of the late Dr. Karl A. Walfred. The term will expire in 1962.

* * *

Dr. Frederic J. Kottke, Minneapolis, has been named President of the American Congress of Physical Medicine and Rehabilitation.

* * *

The postgraduate course in pediatrics under the sponsorship of the Chicago Medical Society was attended by **Dr. R. P. Groschupf,** a member of the Bemidji Clinic.

The Mindaman Orthopedic Society has elected **Dr. E. T. Evans,** Minneapolis, as President for the coming year.

* * *

Drs. Albert Schroeder, Hreidar Agustsson and **Detlof Olson** have announced the appointment of **Dr. C. Sherman Hoyt,** to their practice of pediatrics in Minneapolis.

* * *

Dr. John D. Hagen, of the Austin Clinic, recently attended a postgraduate course at the University of Kansas, Kansas City, Kansas. The theme of the course was Cardiology or the Study of the Heart and Blood Circulation throughout the Body.

* * *

Participating in an advanced seminar in dermatology was **Dr. Henry E. Michelson** of Minneapolis.

* * *

Speakers at the Fall Seminar of the Range Chapter of the American Academy of General Practice in Hibbing included: **Dr. Neil Palm,** St. Paul, surgeon; **Dr. Harold Ravits,** St. Paul, dermatologist; and **Dr. Tague Chisholm,** Minneapolis, pediatric surgeon.

* * *

Dr. William Byrne, who has been engaged in the practice of general medicine in Chisholm, Minnesota, the past two years, is now associated in practice with **Dr. Ernest Sowada** in Minneapolis. He has been in his present location since August 15, 1959.

The Ramsey County Medical Society recently elected its 1960 officers. **Dr. Walter P. Gardner,** St. Paul, was elected president, to succeed **Dr. Gordon Kamman.** Other officers elected were **Dr. Charles C. Cooper,** president-elect for 1961; **Dr. Abbott Skinner,** secretary-treasurer, and **Dr. Joseph M. Ryan,** vice president.

* * *

Twenty-nine fellows of the Mayo Foundation have completed their fellowships or terminated their periods of assignment recently. They include: **Drs. B. R. Aigner, L. W. Blakey, J. R. Calverley, J. P. Glathe, R. A. Kyle, R. L. Larson, K. F. Niehaus, F. E. Roberts, J. C. Schaefer, J. E. Seay, III, R. B. Webb, Jr.,** and **R. J. White.**

* * *

Dr. Mario Fischer, Duluth, recently returned from the 15th Biennial Conference of International Union against Tuberculosis. The meeting of some 1,400 physicians from sixty-three countries was held in Istanbul.

* * *

Former Ellendale physician, **Dr. Morton O. Roan** and his wife, were recently injured in a fire in their Minneapolis apartment. The couple was not injured seriously.

* * *

Professor C. F. W. Illingworth, department of surgery, Western Infirmary, Glasgow, Scotland, gave a lecture on "Choice of Treatment and Prognostic Implications in the Endocrine Approach to Breast Cancer" at the Mayo Clinic, Rochester, Minnesota, on November 19, 1959.

* * *

Dr. John S. Lundy, formerly of the Mayo Clinic staff, left recently for Chicago where he will be associated with the Veterans Research Hospital and a private practice of anesthesiology.

* * *

Dr. Herbert W. Schmidt, Rochester, who was recently elected president of the Mayo Clinic staff, resigned that position when he was elected to the Board of Governors of the staff for a six-year term. **Dr. C. A. Owen, Jr.,** who was elected vice president, will become president of the Mayo Clinic staff. Other officers elected were **Dr. L. O. Underdahl,** secretary, and **Dr. A. M. Olsen,** and **Dr. D. W. Mulder,** councilors.

* * *

Dr. Walter C. Alvarez, Chicago, Illinois, former staff member at Mayo Clinic and emeritus professor of medicine, Mayo Foundation, was presented an award on December 3 by the New York City chapter of the American Medical Writers' Association for distinguished service in the improvement of medical communication. Ceremonies took place at the New York University School of Dentistry in Manhattan.

Doctor Alvarez, former editor of *GP,* is presently editor of *Geriatrics* and editor-in-chief of *Modern Medicine.*

* * *

Dr. Albert Schroeder and **Dr. Hreidar Agustsson,** Minneapolis, presented pediatric subjects on the program of the Camp Release Medical Society at the meeting held in Montevideo in November.

AMBENYL® EXPECTORANT

for quick, effective relief

Antiallergic, antispasmodic, demulcent
Reduces bronchial spasm and congestion
Helps thin mucus and facilitate expectoration

Each fluidounce of AMBENYL EXPECTORANT contains:

Ambodryl® hydrochloride (bromodiphenhydramine hydrochloride, Parke-Davis)	24 mg.
Benadryl® hydrochloride (diphenhydramine hydrochloride, Parke-Davis)	56 mg.
Dihydrocodeinone bitartrate	⅙ gr.
Ammonium chloride	8 gr.
Potassium guaiacolsulfonate	8 gr.
Menthol	q.s.
Alcohol	5%

Supplied: Bottles of 16 ounces and 1 gallon.

Dosage: Every three or four hours—adults, 1 to 2 teaspoonfuls; children, ½ to 1 teaspoonful.

GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Advertisers and Subscribers

Classified advertising—15 cents a word; minimum charge $3.00; key number, 25c additional. Remittance should accompany order. Display advertising rates on request.

Annual Subscription—$5.00. Single copies—$0.50. Foreign and Canadian—$5.50.

Communications concerning advertising and subscriptions should be addressed to Minnesota Medicine, 2642 University Avenue, Saint Paul 14, Minnesota. Telephone Midway 6-2641.

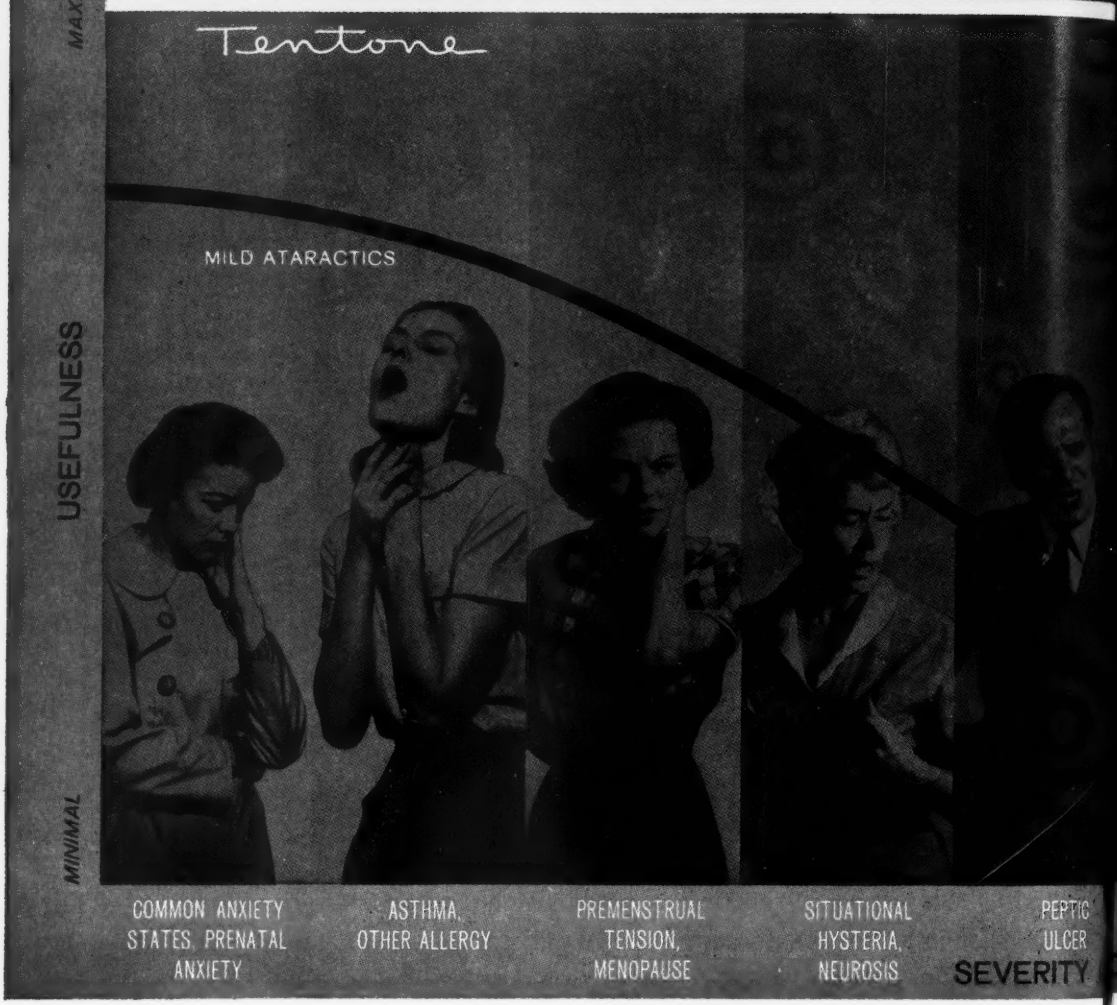
NOW even many cardiac patients may have THE FULL BENEFITS OF CORTICOSTEROID THERAPY

DECADRON—the new and most potent of all corticosteroids, **eliminated fluid retention in all but 0.3 percent of 1500 patients†, and induced beneficial diuresis in nearly all cases of pre-existing edema.**

Decadron*

DEXAMETHASONE

treats more patients more effectively



Therapy with DECADRON has also been distinguished by virtual absence of diabetogenic effects and hypertension, by fewer and milder Cushingoid reactions, and by freedom from any new or "peculiar" side effects. Moreover, DECADRON has helped restore a "natural" sense of well-being.

†Analysis of clinical reports.

when a tranquilizer is warranted.

The extended usefulness of TENTONE is readily apparent

TENTONE® Methoxypromazine Maleate is a new, distinctive phenothiazine... highly active ... for general use in mild and moderate emotional and psychosomatic disorders.

TENTONE elicits a striking, positive calming response[1,2]... with marked reduction of psychic disorientation, and low risk of blood, liver or other organic toxicity and intolerance.[1-4]

TENTONE parallels the weaker ataractics in low incidence of side effects. Freedom from induced depression is apparently even greater.[5]

TENTONE provides a broadly adaptable dosage range (30 to 500 mg. daily) to permit maximum control in cases of varying severity.

TENTONE is also indicated to relieve emotional stress in surgical, obstetric and other hospitalized patients.

CONDITION	RHEUMATIC DISORDERS	ARTERIO-SCLEROSIS, MALIGNANCY	ALCOHOL-DRUG WITHDRAWAL

Why should I use **KANTREX**® Injection* when there are so many other antibiotics available?

Because KANTREX Injection is bactericidal to a wide variety of organisms, including many that are highly resistant to the other antibiotics[3,4,10,12,13,17,18,20,21,23,24,25,27,30,33,35,37]

—organisms such as *Staph. aureus, Staph. albus, A. aerogenes, E. coli, H. pertussis, K. pneumoniae, Neisseria* sp., *Shigella, Salmonella* and many strains of *B. proteus.*

Q *But if I use* KANTREX *Injection, won't that help make bacteria resistant to it also?*

Next page, please .....

*Kanamycin sulfate injection (Bristol)

Q *But if I use* KANTREX *Injection, won't that help make bacteria resistant to it also?*

A A very good question, but it is reassuring to note that in almost two years of clinical use of KANTREX for the treatment of infections for which it is recommended, the emergence of KANTREX-resistant bacterial populations has not been a problem.

Q *My impression is that* KANTREX *is just another neomycin. Isn't that so?*

A Indeed not. The only thing KANTREX and neomycin have in common is a similar antimicrobial spectrum. Otherwise, they're very different: they have different chemical structures; the toxicity of KANTREX is "much less than that of neomycin"[14]; and clinically, KANTREX Injection is practical for systemic administration routinely, while neomycin is not.

Q *You mean that* KANTREX *Injection doesn't have the nephrotoxicity of neomycin?*

A Precisely. It's true that when KANTREX Injection is used, urinary casts – even slight albuminuria or microscopic hematuria – may appear, especially in poorly hydrated patients, but this does not reflect any progressive damage to the kidneys. These signs promptly disappear on adequate hydration or termination of therapy.

Q *Then why do you recommend reduced dosage in patients with renal impairment?*

A Because renal impairment causes an excessive accumulation of KANTREX in the blood and tissues, when usual doses are administered. Since KANTREX Injection is excreted entirely by the kidneys, renal impairment leads

to unnecessarily high and prolonged blood levels; and such excessive concentrations increase the risk of ototoxicity.

Q *Is that why we see reports of patients developing hearing loss during* KANTREX *Injection therapy?*

A Yes. A study of the few reported cases in which patients have suffered impaired hearing will show that in every instance they had pre-existing or concurrent renal impairment, yet received usual or excessive doses of KANTREX Injection. Dosage recommendations for KANTREX Injection emphasize that in patients with renal dysfunction, adequate serum levels can be achieved with a fraction of the dose suggested for patients with normal kidney function – with minimal risk of ototoxicity.

Q *Since urinary tract infections are often accompanied by renal impairment, does that mean I shouldn't use* KANTREX *Injection in such conditions?*

A Not at all. With proper precautions, KANTREX Injection is an excellent drug for the treatment of urinary tract infections, especially those due to *Proteus*, *A. aerogenes* and *E. coli*, even when renal impairment is present.

Q *What are the "proper precautions" in a patient with impaired renal function?*

A The package literature covers them in detail. First, the daily dose should be reduced in such a patient. Then, if he is going to receive KANTREX Injection for 7 days or more, a pre-treatment audiogram should be done, and it should be repeated at appropriate intervals during therapy. If tinnitus or subjective hearing loss develops, or if followup audiograms show significant loss of high frequency response, KANTREX therapy should be discontinued. However, therapy for 7 days or more

is seldom required because the clinical response to KANTREX Injection is so rapid.

Q *Why do you put so much emphasis on* KANTREX'S *"rapid action"? Every antibiotic I've heard about is supposed to be "rapid acting."*

A There is such an abundance of clinical evidence about "rapid acting" that it takes KANTREX Injection out of the "supposed-to" class.[1,2,3,7,8,9,11,15,16,19,21,22,26,29,32,33] Remember, the effectiveness of KANTREX Injection therapy can usually be appraised in 24 to 36 hours. That's definite evidence of rapid action. In fact, one group of investigators reported that "the rapidity with which bacteria are killed by this agent is reflected by the promptness of the clinical response."[29]

Q *Does* KANTREX *Injection cause blood dyscrasias?*

A In extensive clinical and toxicity studies by numerous investigators, as well as almost two years of general use, not a single instance of such toxicity has been reported.

Q *Can I administer* KANTREX *Injection in any other way than by the intramuscular route?*

A Yes. While it's usually given intramuscularly, other routes are practicable: intravenous, intraperitoneal, by aerosol, and as an irrigating solution. Complete instructions are included in the package insert.

Q *So you think I ought to use* KANTREX *Injection as my first choice antibiotic in staph and gram-negative infections?*

A Yes – because all evidence to date indicates that it is bactericidal against a wide range of organisms...rapid acting...does not encourage development of bacterial resistance...is well tolerated in specified dosage...and has not caused any blood dyscrasias.

KANTREX® CAPSULES

for local gastrointestinal therapy... not for systemic infections

Q *Why can't I use* KANTREX *Capsules for systemic medication?*

A Because there is only negligible absorption of KANTREX from the gastrointestinal tract.[3,5,6,8,28,34] Thus, capsules cannot provide effective blood levels.

Q *Then what are* KANTREX *Capsules used for?*

A Preoperative bowel sterilization, and local treatment of intestinal infections due to kanamycin-sensitive organisms.

Q *I've been using neomycin for preoperative bowel sterilization. Why should I switch to* KANTREX *Capsules?*

A Because KANTREX has been rated as "superior to neomycin" for this purpose.[6] It provides rapid and satisfactory control of coliforms, clostridia, staphylococci and streptococci; yeasts do not proliferate; stool concentrations of the drug are exceptionally high; and nausea, vomiting or intestinal irritation have not been observed.[5,6]

Q *What advantages do* KANTREX *Capsules offer me in the treatment of intestinal infections?*

A A high degree of effectiveness against most of the pathogens responsible for such infections: *Salmonella, Shigella, Staph. aureus, E. coli* and *Endamoeba histolytica.* Moreover, their use has been "remarkably free of any side effects."[31]

KANTREX®

INJECTION KANAMYCIN SULFATE INJECTION

INDICATIONS

Infections due to kanamycin-sensitive organisms, particularly staph or "gram-negatives": genito-urinary infections; skin, soft tissue and post-surgical infections; respiratory tract infections; septicemia and bacteremia; osteomyelitis and periostitis.

DOSAGE: INTRAMUSCULAR ROUTE

Recommended daily dose is 15 mg. per kg. of body weight, in 2 to 4 divided doses.

For intramuscular administration, KANTREX Injection should be injected deeply into the upper outer quadrant of the gluteal muscle.

TOXICITY

When the recommended precautions are followed, the incidence of toxic reactions to KANTREX is low. In well hydrated patients under 45 years of age with normal kidney function, receiving a total dose of 20 Gm. or less of KANTREX, the risk of ototoxic reactions is negligible.

In patients with renal disease and impaired renal function, the daily dose of KANTREX should be reduced in proportion to the degree of impairment to avoid accumulation of the drug in serum and tissues, thus minimizing the possibility of ototoxicity. In such patients, if therapy is expected to last 7 days or more, audiograms should be obtained prior to and during treatment. KANTREX therapy should be stopped if tinnitus or subjective hearing loss develops, or if audiograms show significant loss of high frequency response.

OTHER ROUTES OF ADMINISTRATION

KANTREX should be used by intravenous infusion only when the intramuscular route is impracticable. KANTREX can also be employed for intraperitoneal use, aerosol treatment, and as an irrigating solution. See package insert for directions.

PRECAUTIONS

Use of antibiotics may occasionally result in overgrowth of non-sensitive organisms. If superinfection appears during therapy, appropriate measures should be taken.

SUPPLY

Available in rubber-capped vials as a ready-to-use sterile aqueous solution in two concentrations (stable at room temperature indefinitely):

KANTREX Injection, 0.5 Gm. kanamycin (as sulfate) in 2 ml. volume.
KANTREX Injection, 1.0 Gm. kanamycin (as sulfate) in 3 ml. volume.

CAPSULES (for local gastrointestinal therapy; not for systemic medication)

INDICATIONS AND DOSAGE

For preoperative bowel sterilization: 1.0 Gm. (2 capsules) every hour for 4 hours, followed by 1.0 Gm. (2 capsules) every 6 hours for 36 to 72 hours.

For intestinal infections: Adults: 3.0 to 4.0 Gm. (6 to 8 capsules) per day in divided doses for 5 to 7 days. Infants and children: 50 mg. per kg. per day in 4 to 6 divided doses for 5 to 7 days.

PRECAUTION

Preoperative use of KANTREX Capsules is contraindicated in the presence of intestinal obstruction. Although only negligible amounts of KANTREX are absorbed through intact intestinal mucosa, the possibility of increased absorption from ulcerated or denuded areas should be considered.

SUPPLY

KANTREX Capsules, 0.5 Gm. kanamycin (as sulfate), bottles of 20 and 100.

Bristol LABORATORIES INC. • Syracuse, New York

Is one vegetable oil a better cholesterol-depressant than another?

Yes...the one the patient prefers for taste.

No leading vegetable oil can claim superiority over Wesson in its serum cholesterol-depressant effect. As a diet must be eaten to be effective, *the preferred appetite appeal of Wesson* is most important. Through the years, Wesson has been consistently favored over the next selling oil, particularly for flavor (blandness), odor and lightness of color*. Wesson *encourages* the patient to stay on the prescribed diet.

Quality and uniformity you can depend on. Wesson has a poly-unsaturated content better than 50% . Only the lightest cottonseed oils of the highest iodine number are selected for Wesson and no significant variations in standards are permitted in the 22 exacting specifications required before bottling.

Each pint of Wesson contains 437-524 Int. Units of Vitamin E.

Where a poly-unsaturated oil is called for in the diet, Wesson satisfies the most exacting requirements (and the most exacting palates!).

Wesson's Important Ingredients:

Linoleic acid glycerides	50% to 55%
Phytosterol (predominantly beta sitosterol)	0.4% to 0.7%
Total tocopherols	0.09% to 0.12%

Never hydrogenated—completely salt free

*Substantiated by sales leadership for 59 years and reconfirmed by recent tests against the next leading brand with brand identification removed, among a national probability sample.

SYMPOSIUM REPORT:

ALTAFUR in antibiotic-resistant staphylococcal infections

ALTAFUR proved superior to any other single agent against staphylococcal infections encountered in the pediatric section of a general hospital. Introduced during an epidemic of severe staphylococcal pneumonia and bronchiolitis in younger children, ALTAFUR was employed in treating a total of 59 infants or juvenile patients, most of whom had upper or lower respiratory tract involvement. Almost all had been given antibiotics without effect; 34 were judged severely or critically ill. Cures were obtained in 54 of these patients after a 3 to 10 day course of ALTAFUR. There was only one failure (results were inconclusive in the remaining four cases). Mixed infections with Pneumococcus or Streptococcus sp. also responded readily.

ALTAFUR was administered orally in varying dosage: the optimal dose is believed to be about 22 mg./Kg. daily.

Side effects were minimal in these patients, being limited to gastric intolerance in a few cases, usually controllable by giving the drug with or after meals. Laboratory studies performed before and after ALTAFUR treatment revealed no adverse influence on renal, hepatic or hematopoietic function, nor other signs of toxicity.

In vitro, staphylococci isolated in this series proved uniformly susceptible to ALTAFUR, whereas many strains were resistant to a variety of antibotics. With ALTAFUR as with all nitrofurans, the lack of development of significant bacterial resistance is considered a major advantage over other antimicrobials.

Lysaught, J. N., and Cleaver, W.: Paper presented at the Symposium on Antibacterial Therapy, Michigan and Wayne County Academies of General Practice, Detroit, Sept. 12, 1959 (published Nov., 1959)

bright new star

in the antibacterial firmament

ALTAFUR T.M.

brand of furaltadone

the first nitrofuran effective orally in systemic bacterial infections

- Antimicrobial range encompasses the majority of common infections seen in everyday office practice and in the hospital
- Decisive bactericidal action against staphylococci, streptococci, pneumococci, coliforms
- Sensitivity of staphylococci in vitro (including antibiotic-resistant strains) has approached 100%
- Development of significant bacterial resistance has not been encountered
- Low order of side effects
- Does not destroy normal intestinal flora nor encourage monilial overgrowth (little or no fecal excretion)

Tablets of 50 mg. (pediatric) and 250 mg. (adult)
Average adult dose: 250 mg. four times a day, with food or milk
Pediatric dosage: 22-25 mg./Kg. (10-11.5 mg./lb. body weight daily in 4 divided doses

CAUTION: The ingestion of alcohol in any form, medicinal or beverage, should be avoided during Altafur therapy.

NITROFURANS—a *unique* class of antimicrobials
EATON LABORATORIES, NORWICH, NEW YORK

ANNOUNCING SCHERING'S NEW MYOGESIC

RELA™ EASES STRAINS SPRAINS & LOW BACK PAINS...!

CARISOPRODOL

RELA—a new myogesic for better relaxant *and* analgesic therapy—more adept management of spasm and pain in strains, sprains and low back pains.

RELA—though a single drug—is a true myogesic and works rapidly to achieve three desired effects...

Rela relaxes acute muscle spasm
Relief of muscle spasm (96% excellent to good effectiveness)[1]

Rela provides a unique quality of persistent pain relief through its relaxant and analgesic actions
"Relief from pain was usually rapid and sometimes dramatic"[1]

Rela, through relaxation and analgesia, assures daytime ease and nighttime rest
"... A number of patients reported freedom from insomnia which they attributed to freedom from pain."[1]

indications: RELA is most beneficial in those conditions of the musculoskeletal system manifesting pain, stiffness and spasm.

safety: Studies of more than 1400 patients indicate that the toxicity of RELA is exceptionally low. In human subjects, respiratory, blood pressure or blood chemistry changes and/or renal, hepatic or endocrine dysfunction have not been reported.

dosage: The usual adult dosage of RELA is one tablet 3 times daily and at bedtime. RELA has a rapid onset of action, with relief usually apparent within 30 minutes, and persisting for at least 6 hours.

supply: RELA is available as 350 mg., pink, coated tablets in bottles of 30.

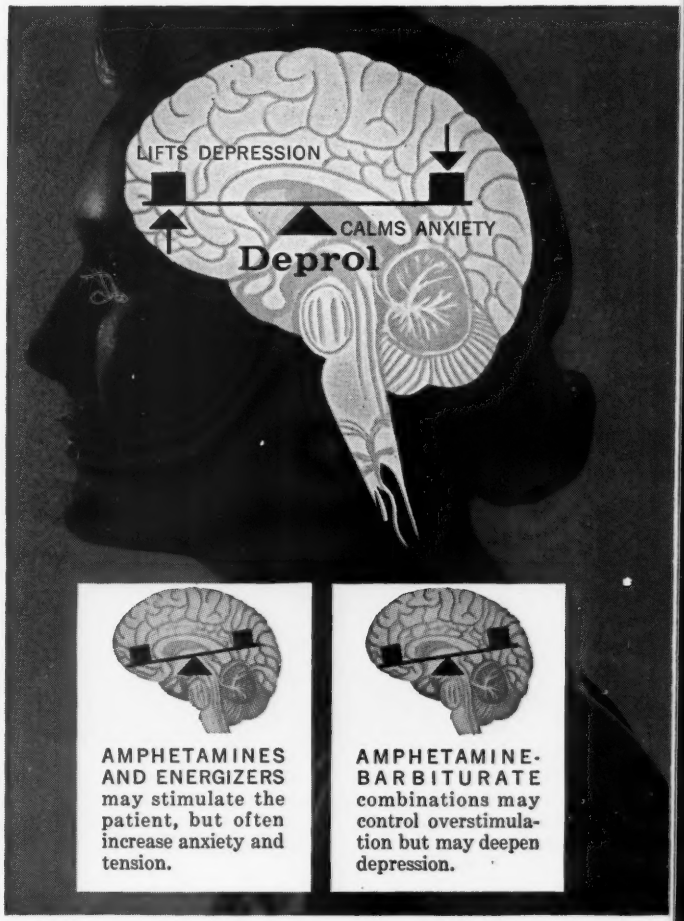
Lifts depression..s

An emotionally balanced patient
Thanks to your treatment and the help of Deprol, her depression is relieved and her anxiety and tension calmed. She eats well, sleeps well, and can return to her normal activities.

..s it calms anxiety!

eprol helps balance the mood y lifting depression as it alms related anxiety



No "seesaw" effect of amphetamine-barbiturates and energizers

While amphetamines and energizers may stimulate the patient—*they often aggravate anxiety and tension.* And although amphetamine-barbiturate combinations may counteract excessive stimulation—*they often deepen depression.*

In contrast to such "seesaw" effects, Deprol lifts depression as it calms anxiety—both at the same time.

Safer choice of medication than untested drugs

Deprol does not produce hypotension, liver damage, psychotic reactions or changes in sexual function.

SPRAINED BACK

"TIGHT NECK"

TRAUMATIC STRAINS AND BRUISES

POSTOPERATIVE MYALGIA

■ Exhibits unusual analgesic properties, different from those of any other drug ■ Specific and superior in relief of SOMAtic pain ■ Modifies central perception of pain without abolishing natural defense reflexes ■ Relaxes abnormal tension of skeletal muscle

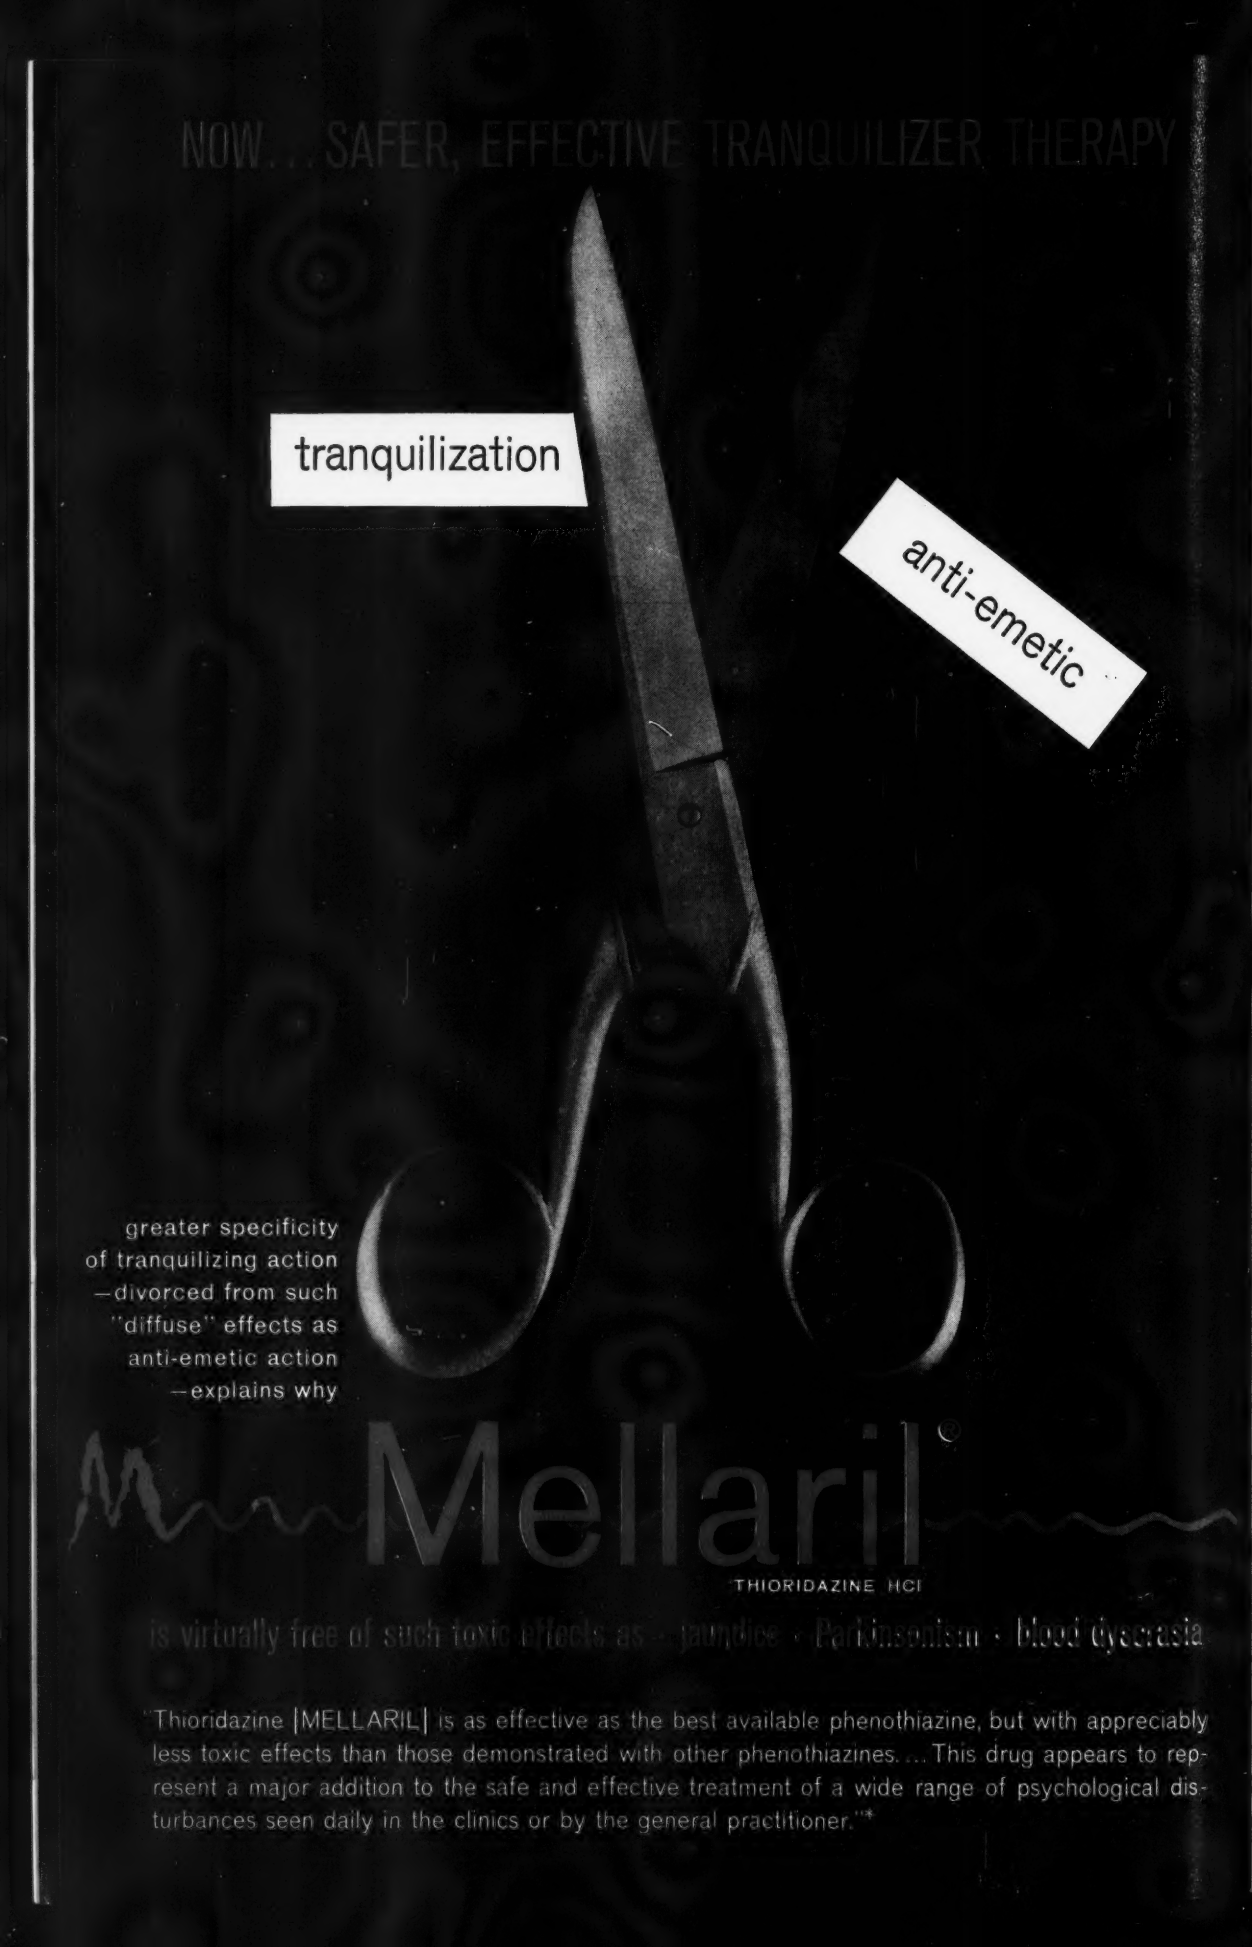
SOMA™

N-isopropyl-2-methyl-2-propyl-1, 3-propanediol dicarbamate

■ More specific than salicylates ■ Less drastic than steroids

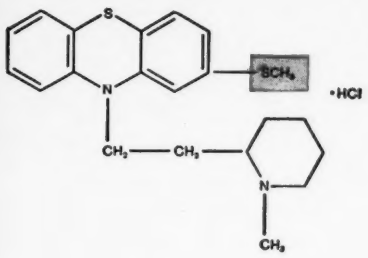
■ More effective than muscle relaxants

SOMA has an unique analgesic action. It apparently modifies central pain perception without abolishing peripheral pain reflexes. SOMA is particularly effective in relieving joint pain. Patients say that they feel better and sleep better with SOMA than with previously used analgesic, sedative or relaxant drugs.
SOMA also relaxes muscle hypertonia, with its stresses on related joints, ligaments and skeletal structures.



ACTS FAST. Pain-relieving and relaxant effects start in 30 minutes and last 6 hours.

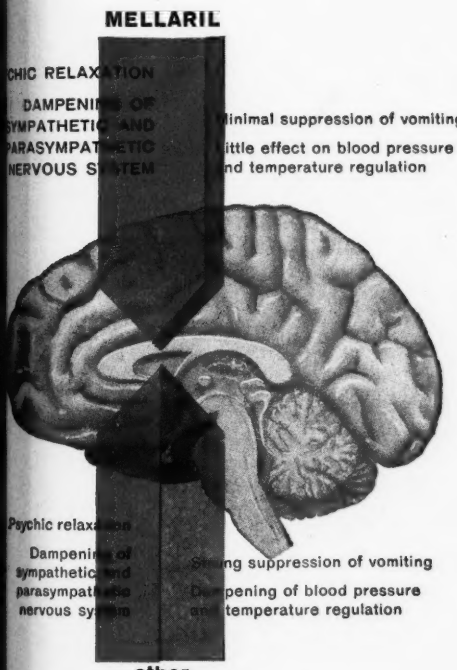
NOTABLY SAFE. Toxicity of SOMA is extremely low. No effects on liver, endocrine system, blood pressure, blood picture or urine have been reported. Some patients may become sleepy, particularly on high dosage.



EASY TO USE. Usual adult dose is one 350 mg. tablet 3 times daily and at bedtime.

SUPPLIED: Bottles of 50 white coated 350 mg. tablets.
Literature and samples on request.

WALLACE LABORATORIES, NEW BRUNSWICK, N. J.



NOW... SAFER, EFFECTIVE TRANQUILIZER THERAPY
tranquilization
anti-emetic
greater specificity
of tranquilizing action
—divorced from such
"diffuse" effects as
anti-emetic action
—explains why
Mellaril®
THIORIDAZINE HCl
is virtually free of such toxic effects as · jaundice · Parkinsonism · blood dyscrasia
"Thioridazine [MELLARIL] is as effective as the best available phenothiazine, but with appreciably less toxic effects than those demonstrated with other phenothiazines. ... This drug appears to represent a major addition to the safe and effective treatment of a wide range of psychological disturbances seen daily in the clinics or by the general practitioner."*

new advance in tranquilization:
reater specificity of tranquilizing action results in fewer side effects

The presence of a thiomethyl radical (S-CH_3) is unique in Mellaril and could be responsible for the relative absence of side effects and greater specificity of psychotherapeutic action. This is shown clinically by:

1 A specificity of action on certain brain sites in contrast to the more generalized or "diffuse" action of other phenothiazines. This is evidenced by a lack of appreciable anti-emetic effect.

2 Less "spill-over" action to other brain areas — hence, absence of undue sedation, drowsiness or autonomic nervous system disturbances.

3 A notable absence of extrapyramidal stimulation.

4 Lack of impairment of patient's normal drive and energy.

5 Virtual freedom from such toxic effects as jaundice, photosensitivity, skin eruptions, blood forming disorders.

INDICATION	USUAL STARTING DOSE	TOTAL DAILY DOSAGE RANGE
ADULTS: Mental and Emotional Disturbances:		
MILD—where anxiety, apprehension and tension are present	10 mg. t.i.d.	20-60 mg.
MODERATE—where agitation exists in psychoneuroses, alcoholism, intractable pain, senility, etc.	25 mg. t.i.d.	50-200 mg.
SEVERE—in agitated psychotic states as schizophrenia, manic depressive, toxic psychoses, etc.:		
Ambulatory	100 mg. t.i.d.	200-400 mg.
Hospitalized	100 mg. t.i.d.	200-800 mg.
CHILDREN: BEHAVIOR PROBLEMS IN CHILDREN	10 mg. t.i.d.	20-40 mg.

LLARIL Tablets, 10 mg., 25 mg., 100 mg.

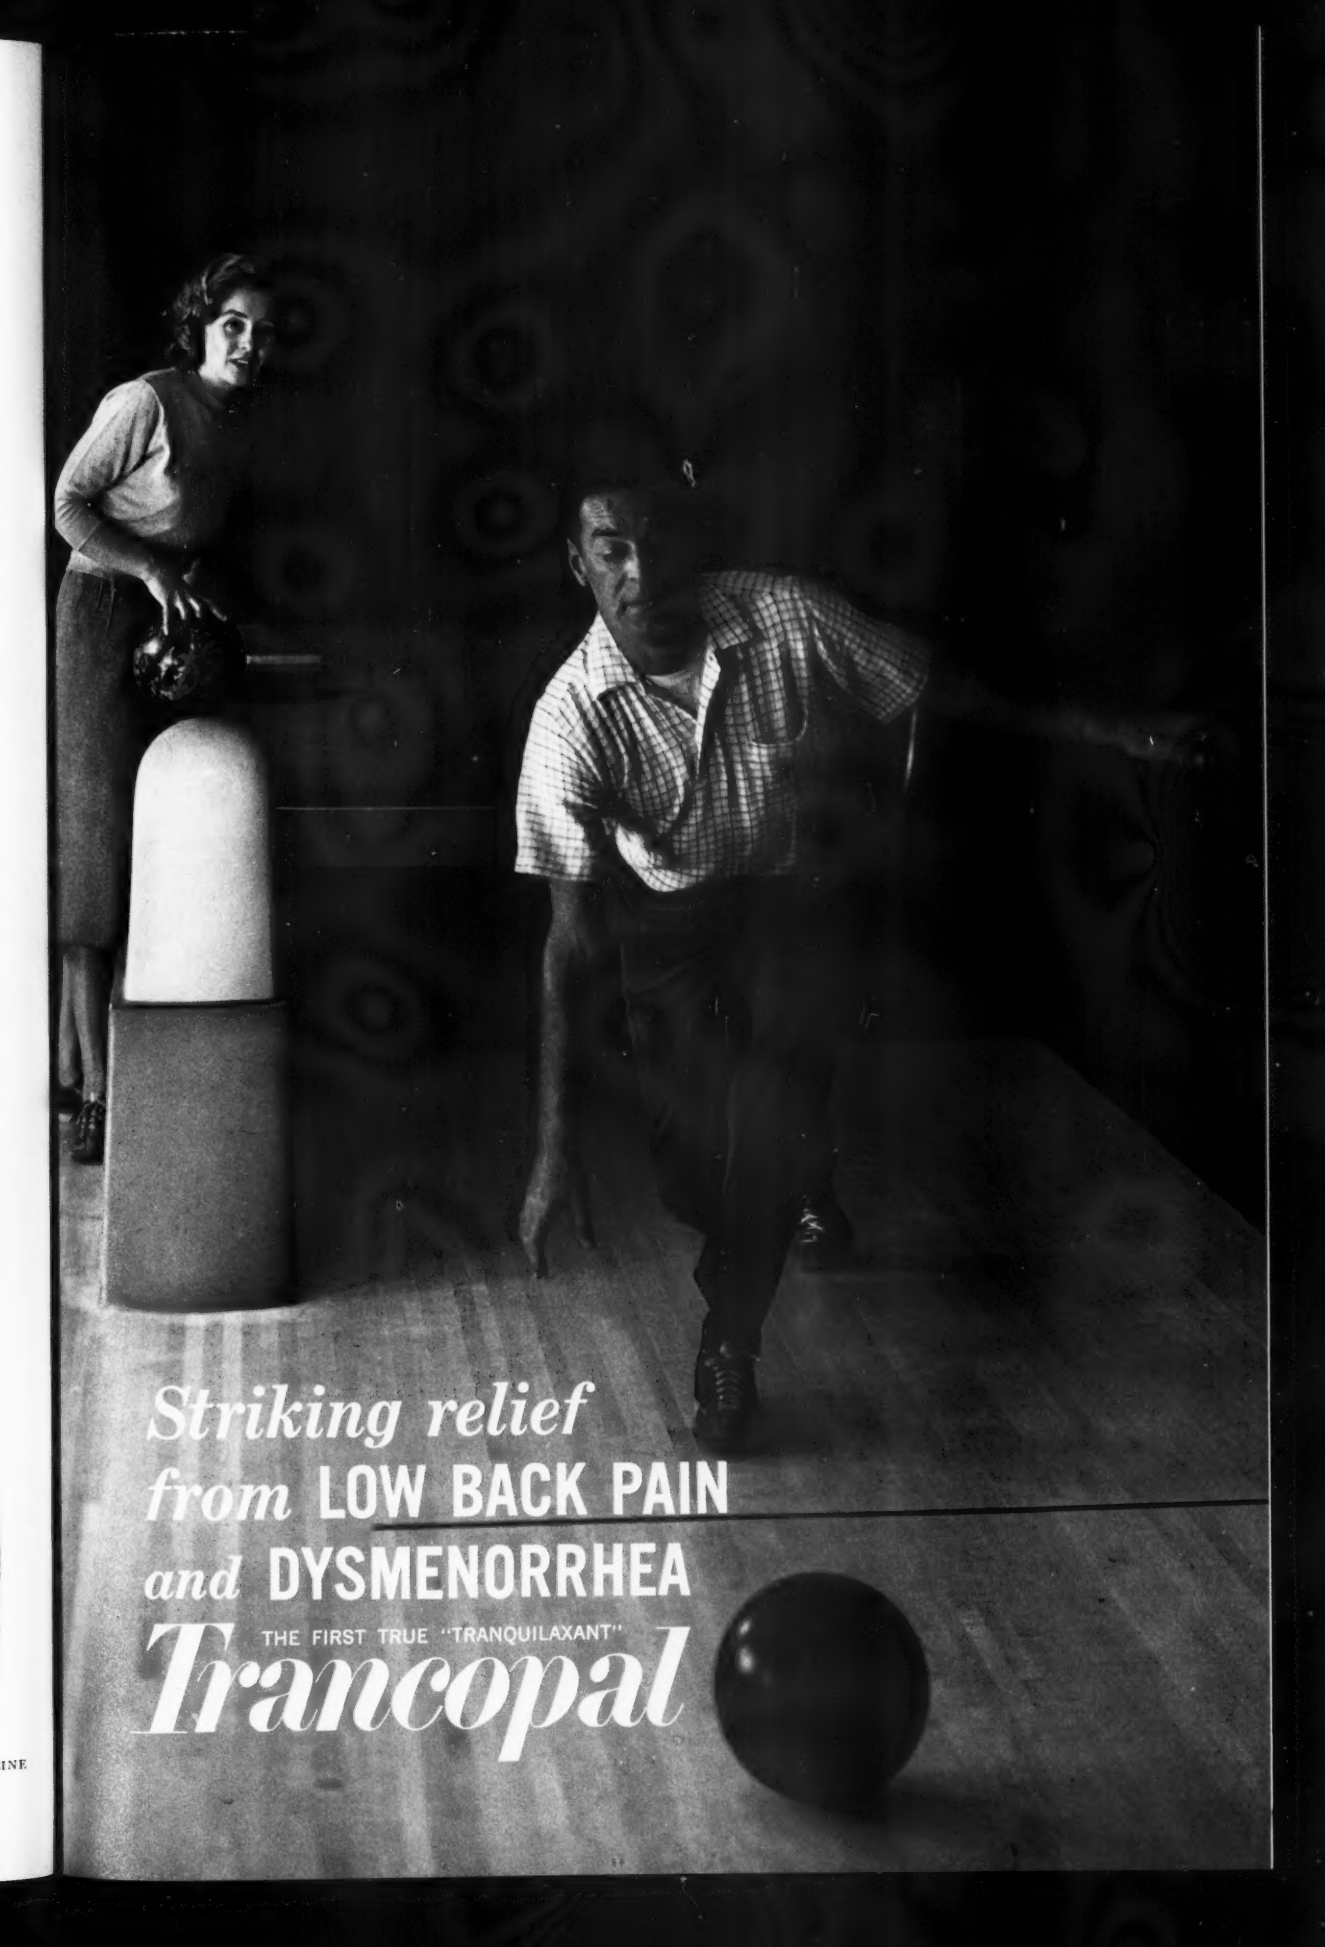
SANDOZ

NEW... to control the pain and the pathogen in acute G. U. infection

AZO KYNEX®

Phenylazodiaminopyridine HCl-Sulfamethoxypyridazine Lederle



COMPLEMENT FOR KYNEX

Adds fast-acting analgesia of phenylazodiaminopyridine HCl. Relieves burning, urgency and pain-spasm. Eases voiding and retention of infected urine.

... **to unexcelled sulfa control** of KYNEX. Lower dosage of just ½ Gm. daily... prolonged action without hazard of crystalluria... reduced toxic potential... not surpassed by any other sulfa drug, singly or in combination. Dosage: Two tablets q.i.d. first day; one tablet q.i.d. thereafter. Each tablet contains: 125 mg. KYNEX in the shell with 150 mg. phenylazodiaminopyridine HCl in the core.

LEDERLE LABORATORIES, a Division of AMERICAN CYANAMID COMPANY, Pearl River, New York Lederle

Striking relief
from LOW BACK PAIN
and DYSMENORRHEA
THE FIRST TRUE "TRANQUILAXANT"
Trancopal

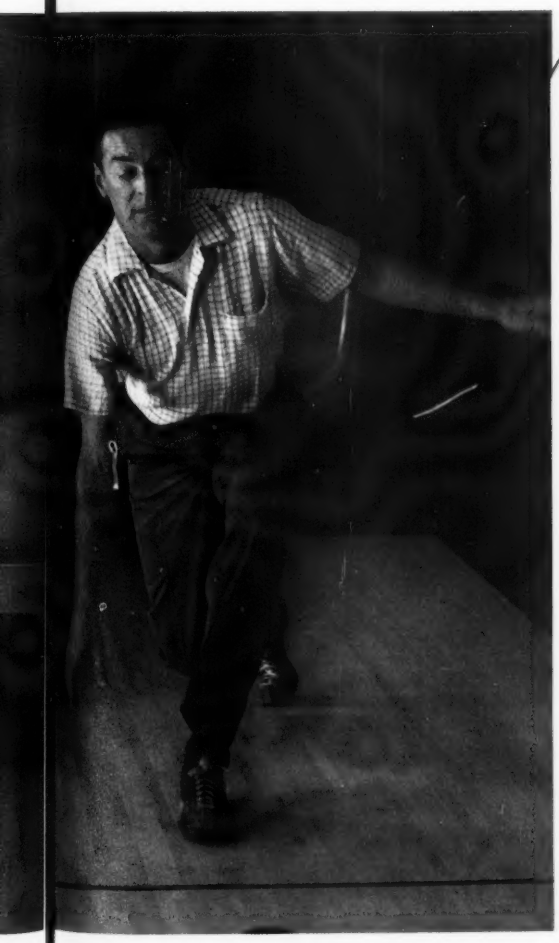
Here is what you can expect when you prescribe

for dysmenorrhea

and premenstrual tension

Case Profile*

A 28-year-old married woman, a secretary in a booking agency, complained of severe and consistent pain and cramps in the abdomen during her menstrual periods. Psychologically, she described the first two days as "climbing the walls." Menarche occurred at age 13. She has a regular twenty-eight day menstrual cycle and a four day menstrual period.



Trancopal was given in a dose of 100 mg. four times a day for the first two days of the four day period. In addition to the relief of the dysmenorrhea she also noticed disappearance of a "bloated feeling" that had previously annoyed her. She has now been treated with Trancopal for one and one-half years with excellent results. Other medication, such as codeine or aspirin with codeine, had relieved the pain, but the patient had had to stay home. Because her father is a physician, many commercial preparations had been tried prior to Trancopal, but no success had been achieved.

Before taking Trancopal this patient missed one day of work every month. For the past year and a half she has not missed a day because of dysmenorrhea.

THE FIRST TRUE "TRANQUILAXANT"

Trancopal®

for low back pain

Case Profile*

A 42-year-old truck driver and mover injured his back while moving a piano. The pain radiated from the sacral region down to the region of the Achilles tendon on the right side. X-rays for ruptured disc revealed nothing pertinent. The day of the injury he was given Trancopal immediately after the physical examination. Although 100 to 200 mg. three times a day were prescribed, the patient on his own responsibility increased the dosage of Trancopal to 400 mg. three times a day. This dosage was continued for three days and then gradually reduced over a ten day period. During this time, the patient continued to drive his truck. The muscle spasm was completely controlled and no apparent side effects were noted.

For the past six months, the patient has continued to take Trancopal 100 to 200 mg. as needed for muscle spasm, particularly during strenuous days.

**Clinical Reports on file at the Department of Medical Research, Winthrop Laboratories.*

Turn page for complete listings of Indications and Dosage.

THE FIRST TRUE "TRANQUILAXANT"

Trancopal

potent MUSCLE RELAXANT

effective TRANQUILIZER

- In musculoskeletal disorders, effective in 91 per cent of patients.[1]
- In anxiety and tension states, effective in 89 per cent of patients.[1]
- Low incidence of side effects (2.3 per cent of patients). Blood pressure, pulse rate, respiration and digestive processes are unaffected by therapeutic dosage. It does not affect the hematopoietic system or liver and kidney function.
- No gastric irritation. Can be taken before meals.
- No clouding of consciousness, no euphoria or depression.

Indications [1-6]

Musculoskeletal:

Low back pain (lumbago, etc.)
Neck pain (torticollis)
Bursitis
Rheumatoid arthritis
Osteoarthritis
Disc syndrome
Fibrositis
Ankle sprain, tennis elbow
Myositis
Postoperative muscle spasm

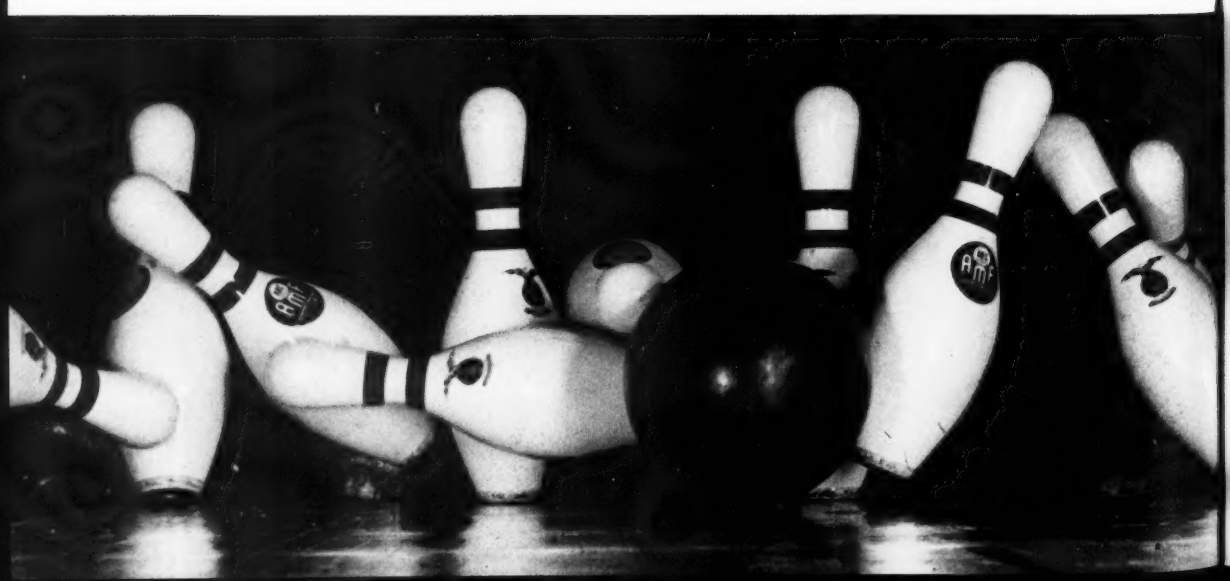
Psychogenic:

Anxiety and tension states
Dysmenorrhea
Premenstrual tension
Asthma
Angina pectoris
Alcoholism

Now available in two strengths:

Trancopal Caplets®,
100 mg. (peach colored, scored), bottles of 100.

NEW STRENGTH ▶



Trancopal Caplets,
200 mg. (green colored, scored), bottles of 100.

Dosage: Adults, 100 or 200 mg. orally three or four times daily. Relief of symptoms occurs in from fifteen to thirty minutes and lasts from four to six hours.

whenever there is inflammation, swelling, pain

VARIDASE

STREPTOKINASE-STREPTODORNASE LEDERLE

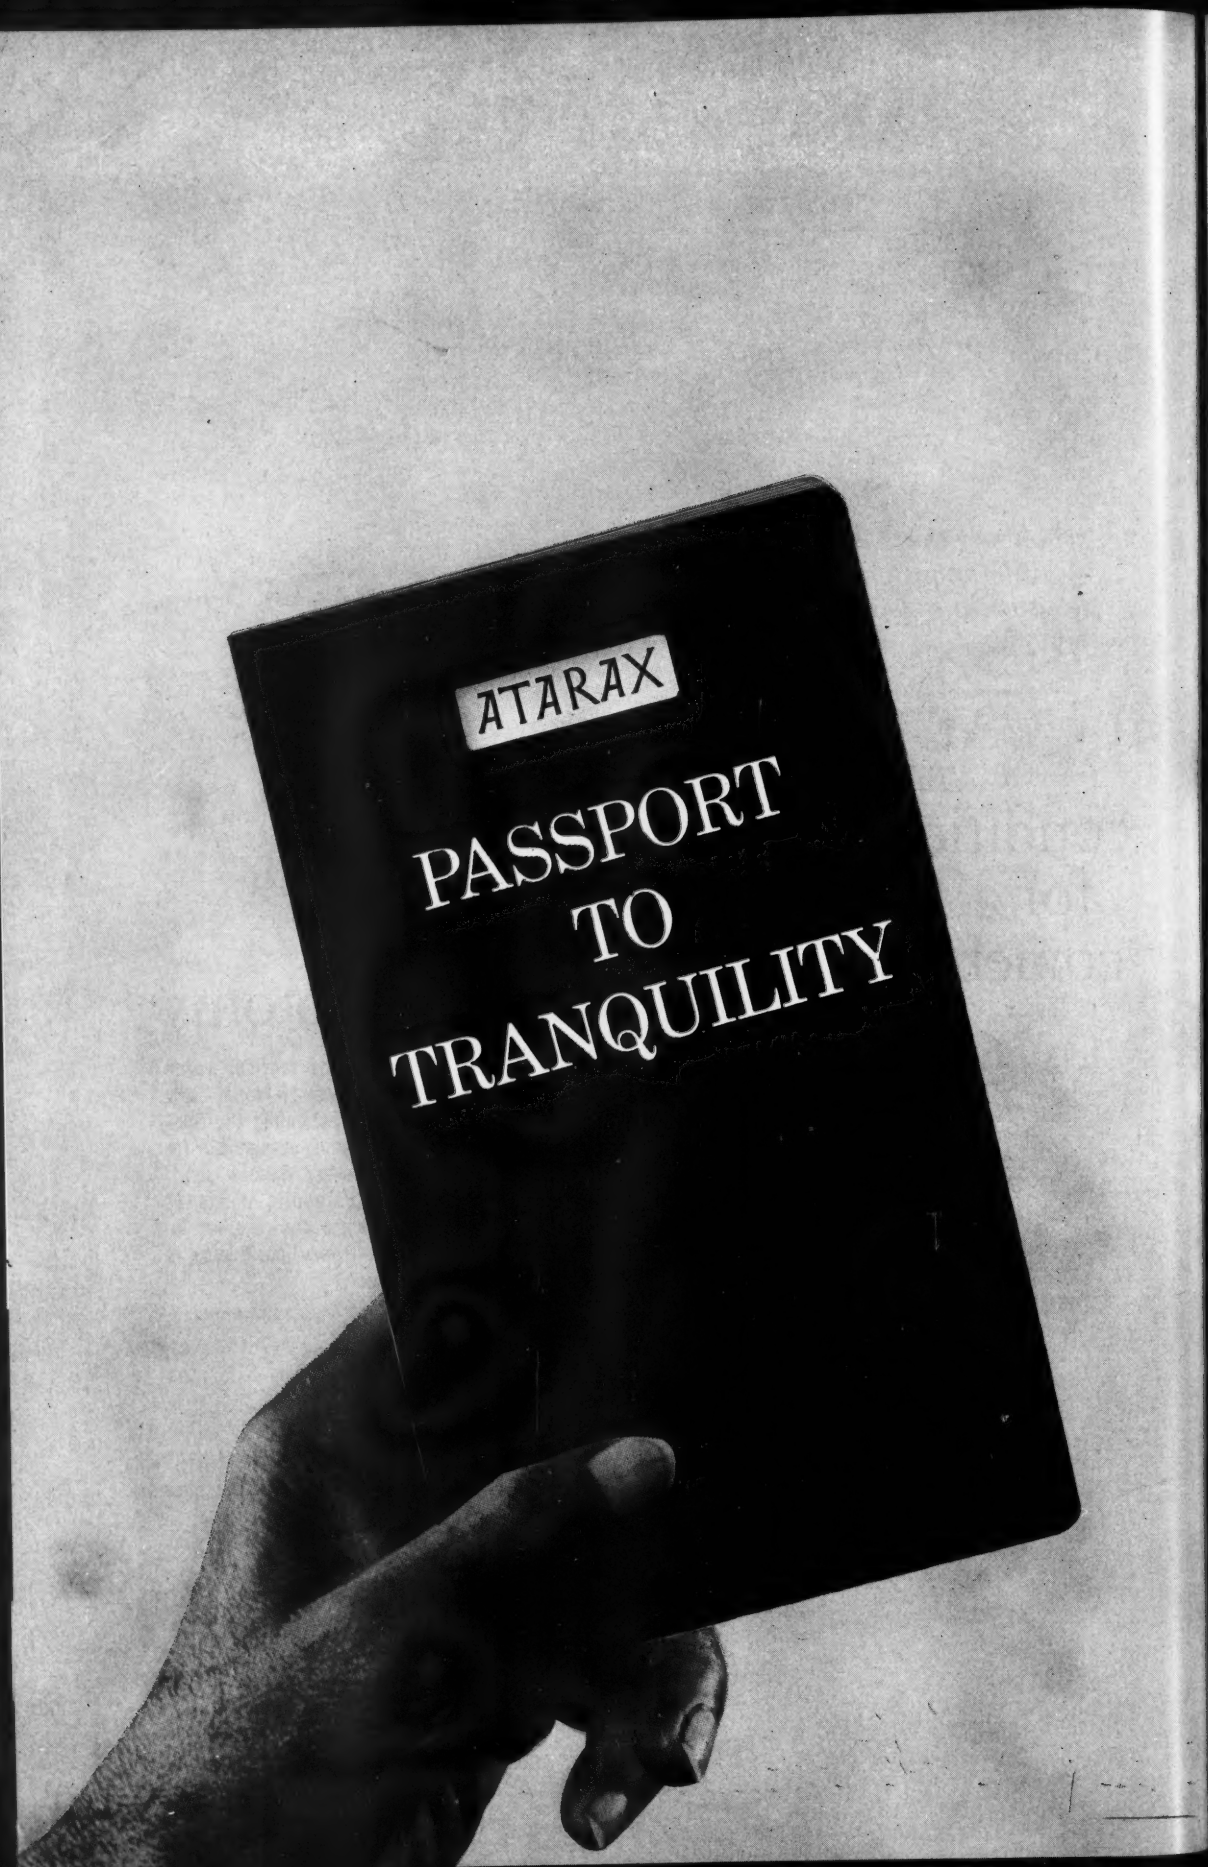
BUCCAL

Tablets

conditions for a fast comeback

as in episiotomy

VARIDASE Buccal provides a simple, natural way to faster, early healing. By activating the fibrinolytic enzymes responsible for normal recovery, VARIDASE shortens the catabolic phase of host response and reverses inflammatory reaction. Edema is reduced.



VARIDASE is not an anti-infective, but by increasing the permeability of the fibrin wall, it eases penetration of natural regenerative factors and fosters healthy tissue growth, making infection less likely.

VARIDASE Buccal Tablets contain: 10,000 Units Streptokinase and 2,500 Units Streptodornase.

Supplied: Boxes of 24 and 100.

Tetracycline-Triple Sulfa Combination (TETREX® c̄ T/S) in the Treatment of INFECTION

It is generally agreed that it is ideal to withhold antibiotic and chemotherapeutic drugs until after sensitivity tests show which antibacterial agent will be most effective. But very often, in actual practice, the physician knows that delay in starting antibacterial treatment may be detrimental to the welfare of his patient. He must then select the therapy to meet the most serious and immediate threats to the patient.

Why Combination Therapy?

Certain infections do not respond as well to a single agent as to a combination. *Hemophilus influenzae* infections, which are frequent in children, are a particularly serious threat to infants and children up to about 3 or 4 years of age since they have not yet built up any appreciable immunity. Serious complications such as influenzal pneumonia, empyema, or meningitis may develop, especially in this age group. In fact, except for those periods when meningococcal meningitis is epidemic, *H. influenzae* is the most frequent cause of meningitis.[1] This gram-negative organism is highly susceptible both to the tetracyclines and to the sulfonamides. Even in severe infections, therapeutic failure can be virtually eliminated by giving sulfonamides plus tetracycline.[1] These two agents together constitute the treatment of choice, and give better results than either alone.[2]

Sulfonamides remain the drugs of choice for all meningococcal infections, including meningitis. They readily penetrate the blood-brain barrier and pass into the cerebrospinal fluid in good concentrations.[3] In treating overwhelming meningococcal infections, and complicating infections of the upper respiratory tract caused by other organisms, the addition of tetracycline to sulfas can be valuable.[4]

In recent years the sulfonamides have again been prescribed more and more frequently. In certain serious infections, better results can be obtained with a combination of antibiotic and sulfonamide than with either drug alone (e.g., severe pneumococcal pneumonia or pneumococcal meningitis[5]). Furthermore, mixed infections, to which young children are particularly susceptible, often respond only to combination therapy such as tetracycline with sulfonamides (TETREX c̄ T/S).

Why Triple Sulfas?

Some sulfonamides, though therapeutically useful, frequently crystallize and cause renal damage. Sulfonamide mixtures are designed to prevent this effect. It is known that different substances can coexist in solution without interfering with each other's solubility. In such a solution each component behaves as if it alone were present. Thus, a much larger total amount of sulfonamide can exist in the urine without precipitating if a mixture is administered than if the same amount of only one compound is given.

Similarly, there is less danger of hypersensitivity with mixtures. The incidence of sensitization varies directly with the dosage and is limited to the particular sulfa given. Simultaneous use of several sulfa compounds, each in partial dosage, tends to keep each drug below its own sensitization level.[3] As with all sulfonamides, it is advisable to check for possible blood dyscrasias, rash, or renal toxicity during extended administration.

TETREX c̄ T/S, by combining only 167 mg. each of sulfadiazine, sulfamerazine, and sulfamethazine, practically eliminates serious renal damage and sensitization reactions due to sulfonamides while retaining the therapeutic efficacy of the total dose.

TETREX c̄ T/S can be administered with confidence in all severe and mixed infections due to tetracycline-sensitive and sulfonamide-sensitive organisms, including infections of the upper respiratory, urinary, and gastrointestinal tracts.

NIAMID*

brightens life for the aged

NIAMID gives the depressed elderly person a new sense of well-being. The family will notice a sunnier outlook, an alert interest in group activities, a renewed awareness of personal appearance, and a return of appetite. Your patient will be more cooperative and less demanding.

You can expect to see the same excellent response to NIAMID in a wide variety of depressive syndromes—acute or chronic, mild or severe, whether associated with long-standing or incurable illness, or masquerading as organic disease.

NIAMID side effects are infrequent and mild, and often lessened or eliminated by a reduction in dosage. NIAMID has not been reported to cause jaundice, and significant hypotensive effects have rarely been noted.

DOSAGE: Start with 75 mg. daily in single or divided doses, and adjust according to patient response. NIAMID acts slowly, without rapid jarring of physical or mental processes. Some patients respond to NIAMID within a few days, but for full therapeutic benefit, most require at least two weeks. NIAMID is available as 25 mg. (pink) and 100 mg. (orange) scored tablets.

Already clinically proved in several thousand patients—

control the tension–treat the trauma

...Pathibamate® 400 200

meprobamate with PATHILON® tridihexethyl chloride Lederle

greater flexibility in the control of tension, hypermotility and excessive secretion in gastrointestinal dysfunctions

PATHIBAMATE combines two highly effective and well-tolerated therapeutic agents:

meprobamate (400 mg. or 200 mg.) widely accepted tranquilizer and . . .

PATHILON (25 mg.)—anticholinergic noted for its peripheral, atropine-like action, with few side effects.

The clinical advantages of PATHIBAMATE have been confirmed by nearly two years' experience in the treatment of duodenal ulcer; gastric ulcer; intestinal colic; spastic and irritable colon; ileitis; esophageal spasm; anxiety neurosis with gastrointestinal symptoms and gastric hypermotility.

Because of individual variation in the intensity of stimuli in gastrointestinal disorders, adequate dosage for optimum control may be expected to vary as well. The dosage strengths of PATHIBAMATE-400 and PATHIBAMATE-200 facilitate individualization of treatment in respect to both the degree of tension and associated G.I. sequelae, as well as the response of different patients to the component drugs.

Supplied: PATHIBAMATE-400—Each tablet (yellow, 1/2-scored) contains meprobamate, 400 mg.; PATHILON tridihexethyl chloride, 25 mg.
PATHIBAMATE-200—Each tablet (yellow, coated) contains meprobamate, 200 mg.; PATHILON tridihexethyl chloride, 25 mg.

Administration and Dosage: PATHIBAMATE-400—1 tablet three times a day at mealtime and 2 tablets at bedtime.
PATHIBAMATE-200—1 or 2 tablets three times a day at mealtime and 2 tablets at bedtime.
Adjust to patient response.

Contraindications: glaucoma; pyloric obstruction, and obstruction of the urinary bladder neck.

CHOICE THERAPY FOR THE "OLDER" PATIENT WITH MILD TO MODERATE HYPERTENSION

℞ Veratrite®

More than 13,000,000 prescriptions attest that Veratrite continues to be the antihypertensive of choice for the older hypertensive patient. Veratrite can be prescribed safely and routinely for those who usually cannot tolerate more potent drugs.

Veratrite now contains cryptenamine which acts centrally to produce a gradual fall in blood pressure, yet improves circulation to vital organs, relieves dizziness and headache, and imparts a distinct sense of well-being. Furthermore, Veratrite achieves its effects with unusual safety and without annoying side effects.

Each Veratrite tabule contains: Cryptenamine (tannates), 40 C.S.R.* Units; Sodium nitrite, 1 gr.; Phenobarbital, ¼ gr. Dosage: 1–2 tabules t.i.d., preferably 2 hours after meals.

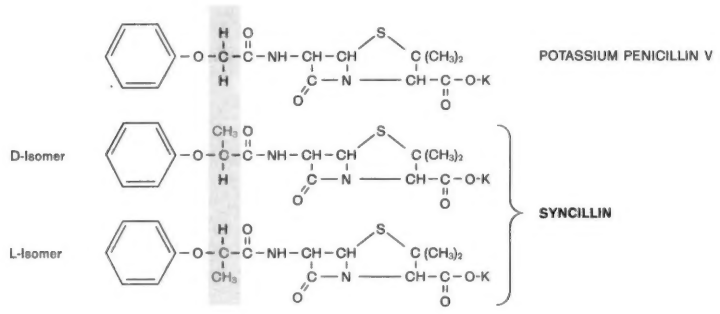
BRISTOL

ORIGIN OF A NEW SYNTHETIC PENICILLIN

In March, 1957, Dr. John C. Sheehan of the Massachusetts Institute of Technology announced the total synthesis of penicillin from common raw materials, thus solving a problem which had baffled research workers for more than 15 years. Although total synthesis was not commercially practicable, this work, sponsored by Bristol Laboratories, made possible the subsequent synthesis of new penicillins not occurring in nature. Later scientists at Beecham Laboratories in England discovered that a key intermediate (6-aminopenicillanic acid) could be produced by a fermentation process. With these achievements, large scale production of synthetic penicillins became feasible.



Organic chemists at Bristol then embarked upon an intensive program to develop better penicillins. Over five hundred were synthesized and underwent preliminary screening. Forty-six showed sufficient promise to warrant further investigation. Extensive microbiological, pharmacological, and clinical screening indicated that one compound, SYNCILLIN, had advantages of major importance over other penicillins.

SYNCILLIN is the N-acylation product of 6-aminopenicillanic acid and α-phenoxypropionic acid (the phenylether of lactic acid). It is freely soluble in water and remarkably resistant to decomposition by acid. The acid stability of SYNCILLIN is equivalent to that of penicillin V at pH 2 and pH 3 at 37° C.[1]

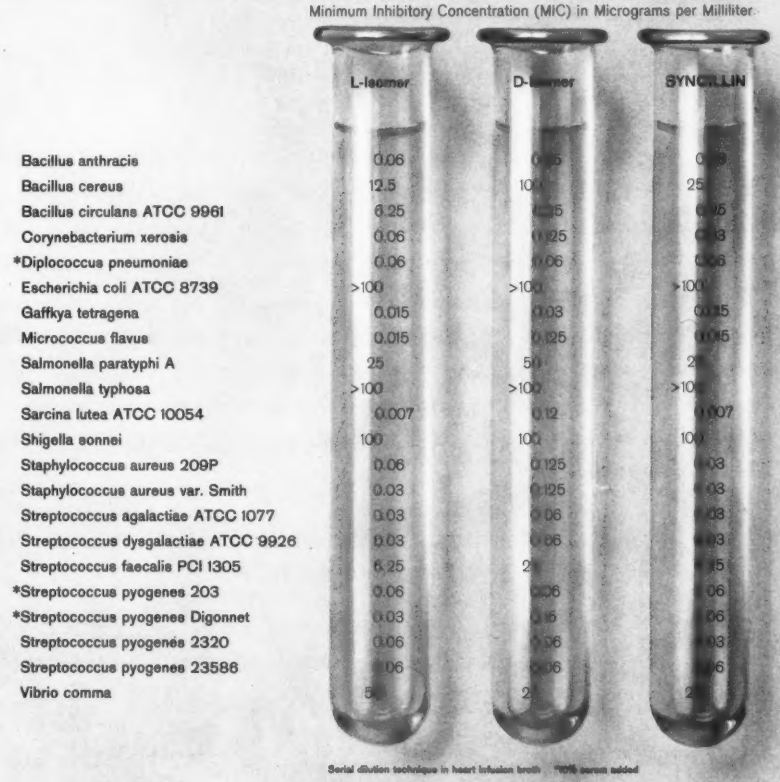
SIGNIFICANCE OF MOLECULAR ASYMMETRY AND ISOMERIC COMPLEMENTARITY

SYNCILLIN has a molecular configuration similar to penicillin V, but contains an additional CH_3 group so positioned as to render the adjacent carbon atom asymmetric. (In the formulae below, the added CH_3 group is shown in blue and the asymmetric carbon atom in red.) As a result, SYNCILLIN occurs as a mixture of two isomers.

Each isomer has been synthesized in essentially pure form and found to possess distinctive chemical and biological properties. The L-isomer is 2 to 17 times more active than the D-isomer against many of the organisms tested. As produced, SYNCILLIN is a mixture of the L-isomer and the D-isomer. As will be shown later, the antibiotic effect of the clinically available mixture, SYNCILLIN, is greater than either isomer alone against many organisms. This phenomenon is referred to here as *isomeric complementarity*.

SYNCILLIN

major therapeutic advantages accompany molecular asymmetry



ISOMERIC COMPLEMENTARITY DEMONSTRATED IN VITRO

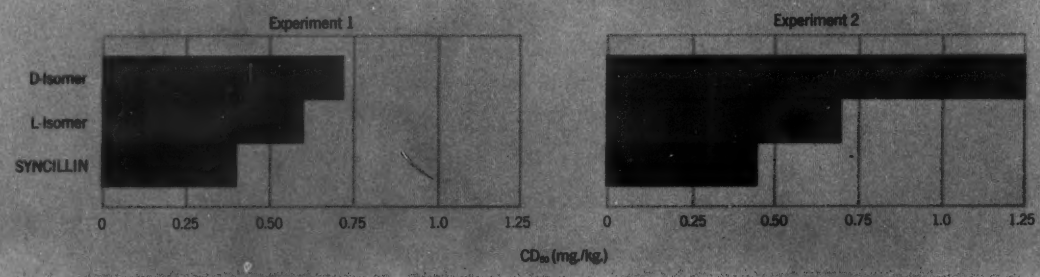
The *in vitro* minimum inhibitory concentration (MIC) of SYNCILLIN and of each of its two component isomers was determined for a variety of common pathogens and laboratory test organisms. As may be seen from Table 1, all three are highly effective against penicillin-susceptible staphylococci and against pneumococci, streptococci, gonococci, and corynebacteria; all are ineffective against Salmonella, *E. coli,* and other gram-negative coliform bacilli.

SYNCILLIN was more active against many of the test strains including some streptococci and staphylococci than either of its components. This demonstrates *in vitro* the phenomenon of isomeric complementarity.

TABLE 1

Minimum Concentrations of SYNCILLIN and Components Required to Inhibit a Wide Range of Bacteria

Serial dilution technique in heart infusion broth. *10% serum added



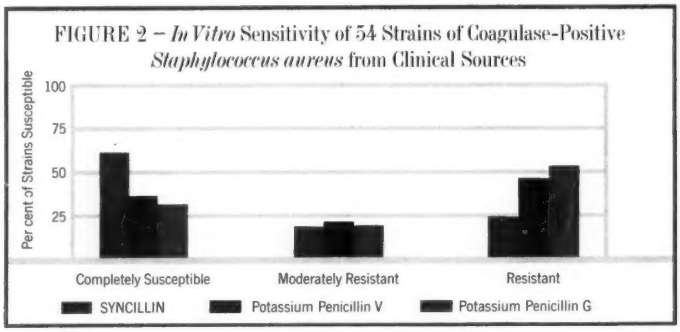
SYNCILLIN

major therapeutic advantages accompany molecular asymmetry

ISOMERIC COMPLEMENTARITY CONFIRMED IN VIVO

To determine the median curative dose (CD_{50}) mice were infected with 100 times the lethal dose of *Staphylococcus aureus*. Each penicillin being tested was administered intramuscularly at the same time, and the dose required to cure half the animals determined. The greater effect of the mixture of the two isomers (SYNCILLIN) is shown in two independent experiments. (See Figure 1.) Note that isomeric complementarity is thus confirmed *in vivo*.

FIGURE 1 — Median Curative Dose (CD_{50}) for *Staphylococcus aureus* (var. Smith) Infections

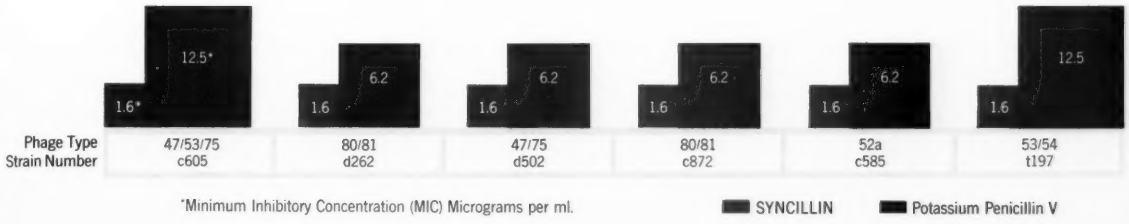


MANY STRAINS OF STAPHYLOCOCCI MORE SENSITIVE TO SYNCILLIN

SYNCILLIN has been tested against a large number of strains of *Staphylococcus aureus* isolated from clinical sources. Many organisms resistant to potassium penicillin G and potassium penicillin V proved sensitive to SYNCILLIN.

Wright[2] performed sensitivity studies on 54 strains, the majority of which were resistant or moderately resistant to penicillin V and penicillin G. Thirty-two (60%) of the strains were sensitive to SYNCILLIN, approximately twice as many as with the other penicillins. (See Figure 2.) In two-thirds of the isolates, SYNCILLIN produced inhibition at concentrations lower than those required for either of the other antibiotics. One strain was more sensitive to penicillin G.

FIGURE 2 – *In Vitro* Sensitivity of 54 Strains of Coagulase-Positive *Staphylococcus aureus* from Clinical Sources

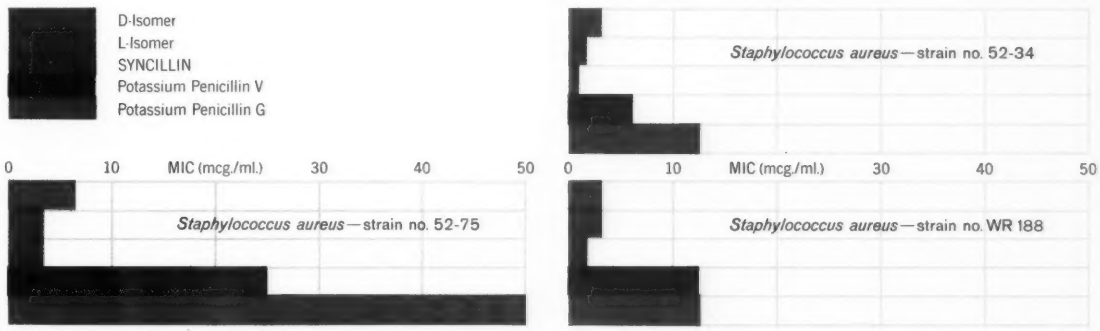


Adapted from Wright[2]

Of equal interest are the findings of White.[3] Six penicillin-resistant strains of staphylococci were isolated from hospital infections. None was sensitive to potassium penicillin V. All were sensitive to SYNCILLIN. (See Figure 3.)

FIGURE 3

Minimum Concentrations of SYNCILLIN Required to Inhibit
Hospital Strains of *Staphylococcus aureus* Resistant to Potassium Penicillin V



The efficacy of SYNCILLIN against the type 80/81 Staphylococcus (dangerous and widespread in hospitals) is worthy of special attention.

The complementary action of the component isomers is also seen with strains of staphylococci resistant to penicillins. Note that SYNCILLIN is more effective than either isomer against strains 52-34 and WR 188. (See Figure 4.) Against all three strains, SYNCILLIN is effective at concentrations below serum levels, while penicillins V and G are ineffective.

FIGURE 4

Minimum Inhibitory Concentrations (MIC) for Coagulase-Positive
Penicillin-Resistant Strains of *Staphylococcus aureus*

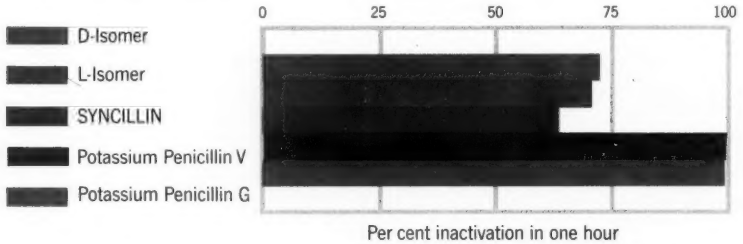
Isomeric complementarity has thus been demonstrated for:

— *certain penicillin-susceptible streptococci, staphylococci and corynebacteria* in vitro *(Table 1)*

— *penicillin-susceptible staphylococci* in vivo *(Figure 1)*

— *penicillin-resistant staphylococci* in vitro *(Figure 4)*

SYNCILLIN



major therapeutic advantages accompany molecular asymmetry

ISOMERIC COMPLEMENTARITY SHOWN BY REDUCED RATE OF INACTIVATION BY PENICILLINASE

Bacterial resistance to penicillin has been attributed to the action of penicillin-inactivating enzymes produced by the invading organisms.[4] As shown in Figure 5, SYNCILLIN is less affected by staphylococcal penicillinase than either of its component isomers – a further demonstration of isomeric complementarity. Further, SYNCILLIN is shown to be less inactivated by this enzyme than penicillin V and penicillin G.

Resistance to SYNCILLIN develops in a slow, step-wise manner characteristic of other penicillins, in contrast to the usually rapid development of resistance to streptomycin.

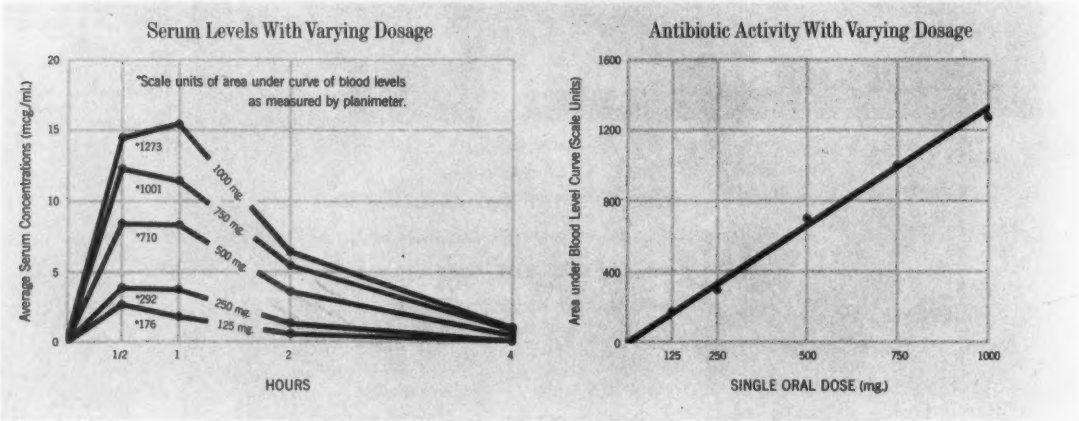


FIGURE 5—Effect of Staphylococcal Penicillinase on Different Penicillins

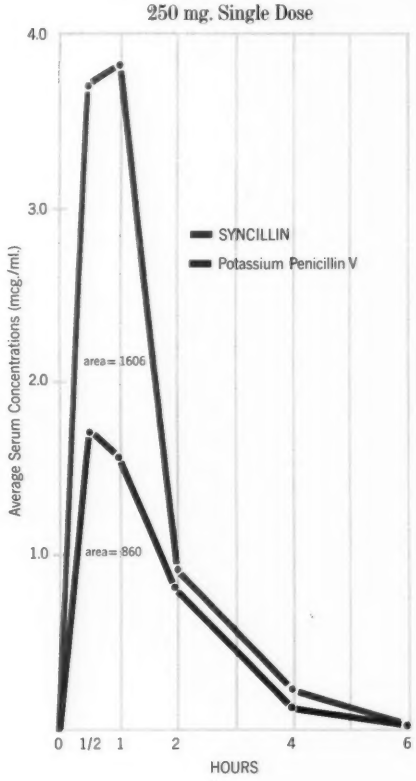
ANTIBIOTIC ACTIVITY DIRECTLY PROPORTIONAL TO ORAL DOSAGE

Cronk[5] studied blood levels after administering varying amounts of SYNCILLIN. (Figure 6.) Total antibiotic activity (obtained by measuring areas under curves with a planimeter) increases rapidly as the dose is doubled. These data show that increased dosage markedly increases serum concentration and thus may enhance the drug's effectiveness.

FIGURE 6



BLOOD LEVELS TWICE AS HIGH AS WITH POTASSIUM PENICILLIN V AFTER ORAL ADMINISTRATION

Wright[6] performed comparative crossover blood level studies on volunteer subjects receiving equivalent amounts of potassium penicillin V and SYNCILLIN. The peak concentrations attained during the first hour after administration were twice as high with SYNCILLIN.

The total antibiotic activity as measured by the area under the curves (see Figure 7) indicates an almost 2 to 1 superiority of SYNCILLIN (1606) over potassium penicillin V (860).

The higher blood levels may be of value with organisms of only moderate penicillin-sensitivity where doubling the blood concentration may be essential for effective bactericidal action. In addition these higher levels may be necessary where there is infection in areas with a poor blood supply.[7] Under these circumstances a higher blood concentration may provide the increased diffusion pressure required to deliver adequate amounts to the tissue.

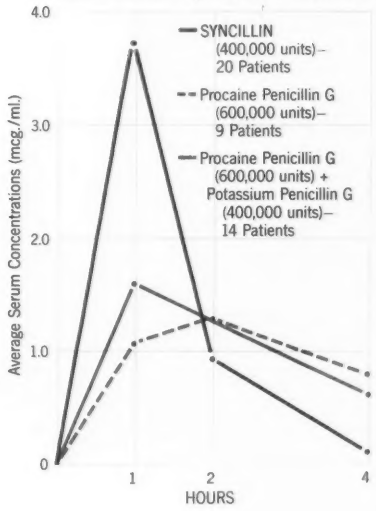


FIGURE 7
20 Subject Crossover
250 mg. Single Dose

BLOOD LEVELS MUCH HIGHER THAN WITH INTRAMUSCULAR PENICILLIN G

In addition, blood levels attained with oral SYNCILLIN[6] are much higher than those with intramuscular penicillin G.[8a, b] (See Figure 8.) Note that the level at one hour for SYNCILLIN (3.8 mcg./ml.) is more than twice as high as with procaine penicillin G, even when reinforced with potassium penicillin G (1.6 mcg./ml.). Since penicillins are *bactericidal,* these intermittent high serum levels can be clinically significant. Thus, SYNCILLIN offers the promise of superior efficacy via the safer oral route.

FIGURE 8—Serum Levels after Oral Administration of SYNCILLIN (250 mg.) and after Intramuscular Injection of Penicillin G

SYNCILLIN

major therapeutic advantages accompany molecular asymmetry

REDUCED HAZARD OF SERIOUS ALLERGENICITY BY SAFER ORAL ROUTE

SYNCILLIN has been administered in multiple doses to 437 patients and volunteers. One patient developed itching during therapy, possibly an allergic side effect. Another had a purpuric rash, but no relationship to SYNCILLIN was established. No reactions were observed in 9 patients with a known history of sensitivity to penicillin.

While the above data suggests the possibility of reduced allergenic hazard, no definite conclusions may be drawn at this time. *The usual precautions for oral penicillin therapy should be observed.* Patients with histories of asthma, hay fever, urticaria, or previous penicillin-sensitivity should especially be watched carefully. Since SYNCILLIN is administered orally, it may be expected to be safer than parenteral penicillin.

As Flippin[9] recently stated, "... it is well established that serious allergy to the drug [penicillin] is most likely to occur following parenteral administration, especially after repeated intramuscular injections; the oral route is least likely to initiate severe hypersensitivity reactions. This can be explained partly by the fact that when reactions develop following oral medication, they are usually slow enough to treat symptomatically; thus the progression of the reaction can usually be interrupted. . . . In view of the relatively high incidence of severe allergy to injectable penicillin, it would seem advisable to employ oral penicillin routinely, except in the control of infections involving the blood stream, endocardium, meninges, etc., in which cases the parenteral route remains the preferred treatment."

SYNCILLIN, like other penicillins, is essentially free of other toxicity. No hematopoietic, hepatic, or renal toxicity was observed in 210 volunteers receiving 1 gm. daily for 2 to 3 weeks.[10]

CLINICAL EFFICACY DEMONSTRATED IN PENICILLIN-SENSITIVE INFECTIONS

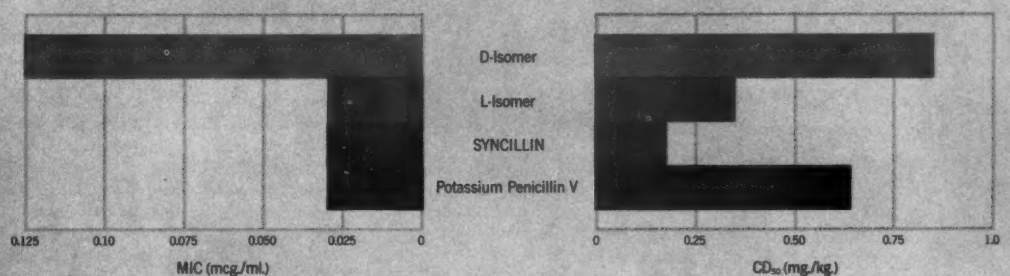
Clinical trials conducted by Blau and Kanof,[11] White,[12] Prigot,[13] Robinson,[14] Dube,[15] Ferguson,[16] Rutenburg,[17] Richardson,[18] Bunn,[19] Cronk,[5] Kligman,[10] and Yow [20] demonstrated the efficacy of SYNCILLIN in a variety of streptococcal, staphylococcal, pneumococcal, and gonococcal infections. Conditions treated included respiratory, skin, soft tissue, wound, and chronic urinary tract infections; acute gonorrhea; cellulitis; septicemia; otitis media; gingivitis; and Vincent's angina. In a few patients SYNCILLIN was used for rheumatic fever or gonorrheal prophylaxis.

One hundred seventy-two of one hundred ninety-six patients responded favorably to SYNCILLIN. The failures included 1 patient with pustular dermatoses, 10 elderly patients with chronic urinary tract infections, 1 patient with gonorrhea, 1 patient with a gram-negative infection, and 10 patients with staphylococcal infections. Lack of response of staphylococcal infections was attributed to the presence of resistant organisms or local suppurative foci requiring drainage.

SYNCILLIN

major therapeutic advantages accompany molecular asymmetry

Relatively few side effects were encountered. One patient experienced moderate itching of the skin which was controlled by an antihistamine. Another reported pruritus ani which did not interfere with therapy. Diarrhea occurred in 4 instances. There was one purpuric rash, but no relationship to SYNCILLIN could be established.



Clinical response usually begins within 24 hours in infections susceptible to SYNCILLIN. Recovery occurs in 4 to 7 days depending upon the severity of the infection. Gonorrheal infections respond very promptly to SYNCILLIN; 500 mg. b.i.d. for two days usually produce bacteriologic cures.

IMPROVED ANTIBIOTIC EFFECT FROM COMPLEMENTARY ACTION OF ISOMERS

SYNCILLIN is a mixture of isomers. The L-isomer is 2 to 17 times more active than the D-isomer against many of the organisms tested. Furthermore, the D- and L-isomers have other distinguishing chemical, pharmacological, and microbiological properties. Their *in vivo* and *in vitro* activities differ for many important pathogens. *Against many of the organisms tested, the combination of isomers* (SYNCILLIN) *is much more active than the stronger isomer alone.* This phenomenon of isomeric complementarity is not always demonstrable, for in a few instances SYNCILLIN is slightly less active.

Isomeric complementarity has previously been demonstrated *in vitro* (Figure 4) and *in vivo* (Figure 1). Figure 9 reveals a third form of superiority related to isomeric complementarity. Equal concentrations of SYNCILLIN and penicillin V were required to inhibit this growth of staphylococci *in vitro*. But, *in vivo*, a much smaller amount of SYNCILLIN *(one-third that of penicillin V)* was effective in an experimental infection with the same strain. These observations on complementary action indicated the advantage of producing the mixture of isomers as the medication to be made available for clinical therapy.

FIGURE 9 — Comparison of CD_{50} and MIC Values Against *Staphylococcus aureus* (var. Smith)

Isomeric complementarity has thus been demonstrated for:

— *certain penicillin-susceptible streptococci, staphylococci and corynebacteria* in vitro *(Table 1)*

— *penicillin-susceptible staphylococci* in vivo *(Figures 1 and 9)*

— *penicillin-resistant staphylococci* in vitro *(Figure 4)*

— *staphylococcal penicillinase antibiotic inactivation (Figure 5)*

SYNCILLIN

major therapeutic advantages accompany molecular asymmetry

Indications:

SYNCILLIN is recommended in the treatment of infections caused by pneumococci, streptococci, gonococci, corynebacteria, and penicillin-sensitive staphylococci. In addition, SYNCILLIN is effective against certain strains of staphylococci resistant to other penicillins.

SYNCILLIN, like other oral penicillins, is not recommended at the present time in deep-seated or chronic infections, subacute bacterial endocarditis, meningitis, or syphilis.

Dosage:

125 mg. or 250 mg. three times daily, depending on the severity of infection. Larger doses (e.g., 500 mg. t.i.d.) may be used for more severe infections. SYNCILLIN may be administered without regard to meals.

Beta hemolytic streptococcal infections should be treated with SYNCILLIN for at least ten days.

Precautions:

While present data suggest the possibility of reduced allergenic hazard, no definite conclusions may be drawn at this time. *Therefore the usual precautions with oral penicillin therapy must be observed.* Patients with histories of asthma, hay fever, urticaria, or previous reactions to penicillin should be watched with special care.

Diarrhea has been reported occasionally following heavy dosage. If this occurs, the interval between dosages should be lengthened.

If superinfection occurs during therapy, appropriate measures should be taken.

Since some strains of staphylococci are resistant to SYNCILLIN as well as to other penicillins, cultures and sensitivity tests should be performed where indicated by clinical judgment. As is true with all antibiotics, clinical response does not always correlate with laboratory bacterial sensitivity reports.

Supply:

125 and 250 mg. tablets, bottles of 25 and 100. 125 mg. powder for oral solution, 60 ml. vials.

Deaner®

deanol acetamidobenzoate

- 'Deaner' may be prescribed with little or no concern over side effects even in the presence of liver disease, diabetes, cardiovascular disease, and a long list of other chronic conditions, except grand mal epilepsy (only contraindication).
- 'Deaner' *is not a monoamine oxidase inhibitor;* hence it is not necessary to monitor its administration with repeated, expensive laboratory tests.
- This notable freedom from side effects endows Deaner's long-term administration with easier patient supervision, better patient cooperation, and greater safety.
- Dosage is simple—initially, 50 mg. (2 tablets) daily in the morning. *Gradually, apathy and defeat are transformed into affability and renewed interest and vigor.*

Write for details and the applicability of 'Deaner' in behavior problems of children
